Volume 41 Number 1

MECHANICAL ENGINEERING

THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

JANUARY, 1919

PUBLISHED MONTHLY BY

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

29 West Thirty-ninth Street, New York

PRICE 35 CENTS A COPY, $3.00 A YEAR; TO MEMBERS AND AFFILIATES, 25 CENTS A COPY, $2.00 A YEAR. POSTAGE TO CANADA, 50 CENTS ADDITIONAL; TO FOREIGN COUNTRIES, $1.00 ADDITIONAL

Entered as second-class matter, January 4, 1912, at the Post Office, New York, N. Y., under the act of March 3, 1879.
Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized on July 8, 1918.

THE ENGINEERING INDEX

Now Conducted by The American Society of Mechanical Engineers and Published Monthly in The Journal of the Society

THE Engineering Index, published for 25 years in *The Engineering Magazine* and its successor, *Industrial Management*, and universally regarded as the standard index to engineering periodical literature, has been acquired by THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, and hereafter will be compiled and published by this Society. The first issue of the Index under its new management appears in this number of THE JOURNAL.

As heretofore, The Engineering Index will be regularly issued in three different forms:

1. As a part of THE JOURNAL of the Society, price $3.00 a year.
2. As a separate monthly publication for libraries or individuals desiring to clip the items for indexing purposes, price $3.00 a year.
3. As an annual volume in which all the items for the year are collected, price $3.00 a volume.

These prices are all subject to change.

The Engineering Index originated with Prof. J. B. Johnson of Washington University, St. Louis, Mo., in 1883 and for 12 years was prepared under his direction and published by the Association of Engineering Societies. It was then taken over by The Engineering Magazine Company of New York and has since had the personal attention of Mr. John R. Dunlap, the president of that company, who has found it to be a widely appreciated undertaking by engineers throughout the world. The development of his magazine in the specialized field of industrial management, however, made it seem desirable to place The Index in the hands of an engineering organization covering a broader field and serving engineers engaged in more varied activities.

For some time past THE JOURNAL of the A.S.M.E. has contained an extensive list of "Selected Titles of Engineering Articles." The acquiring of the Engineering Index means that this work must be extended to cover a broader field, and in this the Society will have the fullest coöperation of the Engineering Societies Library with its wonderful collection of engineering periodicals, comprising 1100 titles from all parts of the world, in some 10 different languages.

An idea of the possibilities of this undertaking and its usefulness to the profession can be judged by reference to the following list of publications which are among those regularly received in the Library in normal times and regularly reviewed by the engineering staff of the Society in the preparation of its index material:

Partial List of Periodicals to be Reviewed in the Engineering Index.

Aero Club d'Italia, Navigazione aerea, Rome
Acetylene Lighting and Welding Journal, London
Acetylene Journal, Chicago
Aeronautical Journal, London
Aeronautics, London
Aérophile, Paris
Allgemeine Automobil-Zeitung, Berlin
American Academy of Arts and Sciences, Proceedings, Boston.
American Architect, Boston
American Association for the Advancement of Science, Proceedings, Philadelphia
American Blacksmith, Buffalo
American Ceramic Society, Transactions, Columbus
American Chemical Journal, Baltimore
American Chemical Society, Proceedings, Easton, Pa.
Industrial and Engineering Chemistry, Journal (publ. by American Chemical Society), Easton, Pa.
Chemical Abstracts (publ. by American Chemical Society), Easton, Pa.
American Chemical Society, Journal, Easton, Pa.
American City, New York
American Concrete Institute, Journal, Philadelphia
American Contractor, Chicago
Aera (publ. by American Electric Railway Association), New York
American Electric Railway Association, Proceedings, New York

Spring Meeting

The Spring Meeting for 1919 will be held at Detroit and the date has been tentatively announced as June 17 to 20.

Coming Sections Meetings

Buffalo: A meeting has been arranged for January 29, at the Hotel Statler, at 8.30 p. m. Nathan L. Lieberman will deliver an address on Horsepower Requirements of Aeroplanes and Power Consumption through Parasite Resistance.

Minnesota: On January 6 the Section will hold a regular meeting at the Midway Branch of the St. Paul Association of Commerce. Prof. Peter Christianson of the School of Mines, University of Minnesota, will deliver the address of the evening.

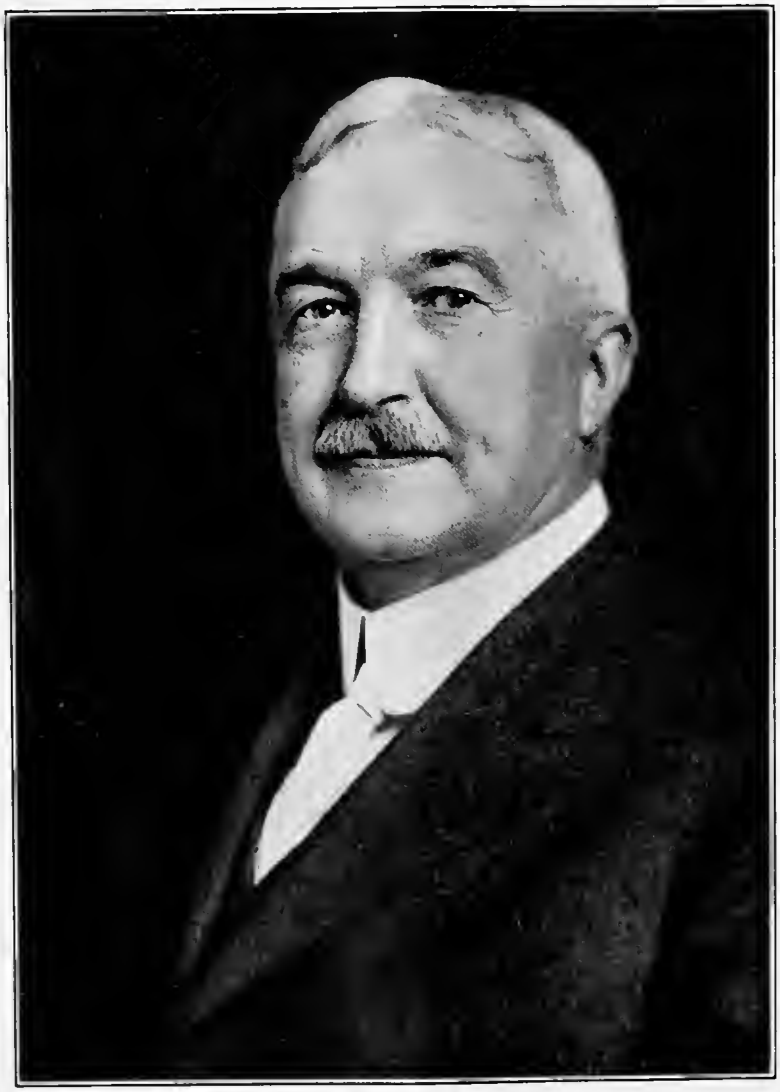
New Haven: Douglas K. Warner will speak before the members of the New Haven Branch on January 8, at 8 p. m., in the Mason Laboratory. The subject of his address will be Friction of Ball Bearings.

New York: A meeting is planned early in January at the Engineering Societies Building, at which W. W. Macon, Chairman of the Executive Committee of the New York Section, will relate his experiences abroad as a member of the delegation of technical editors.

Philadelphia: The Section will hold its monthly meeting in the Engineers' Club on January 28. William B. Dickson, Vice-President and Treasurer of the Midvale Steel and Ordnance Company, New York, will deliver an address on the subject of Relations between Employer and Employee.

San Francisco: The Section is planning an informal smoker to be held at the Engineers' Club early in January.

[illegible]



MORTIMER ELWYN COOLEY
PRESIDENT 1919
THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

MECHANICAL ENGINEERING

THE JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Volume 41 January, 1919 Number 1

THE ANNUAL MEETING

THE thirty-ninth Annual Meeting of the Society held December 3 to 6, was a meeting strong and well-rounded out in its various elements, professionally and socially, simply conducted in accord with the spirit of the times, yet an occasion of very genuine pleasure to the large number in attendance. The total registration was 1717, of whom 1040 were members.

In this number of THE JOURNAL will be found an account of many of the features, including the conferring of Honorary Membership at the opening session and the President's address; the keynote session: the evening lectures, the important business meeting and the deliberations of the newly-formed Committee on Aims and Organization, the largest committee of the Society, representative of the Sections as well as of the Society at large. Accounts of the strictly technical sessions, those devoted to machine-shop subjects, refrigeration, power plants, textiles and miscellaneous subjects are reserved for a future number.

All of the events were held in the Engineering Societies Building. On Monday and Tuesday the Committee on Aims and Organization held several conferences, the conclusions of which were summarized in a progress report presented at the Business Session on Wednesday morning by the Chairman, L. C. Marburg, and published complete in this number.

President Main's address on Tuesday evening on Broader Opportunities for the Engineer voiced the desire for greater usefulness and the need for greater responsibilities which is felt alike by those in all professions and walks of life at the present time. The evening of the President's address was made still more notable by the double distinction of Honorary Membership conferred upon Charles M. Schwab and Orville Wright, with happy and appropriate remarks interspersed by Dr. John A. Brashear.

On each of the other evenings, Wednesday and Thursday, were lectures of wide appeal covering some of the important engineering work of the Army and Navy. On Wednesday evening Lieut.-Commander William L. Cathcart spoke on the Engineering Achievements of the Bureau of Steam Engineering During the War, illustrated by many lantern slides. He was followed by Lieut-Commander D. C. Buell, who gave the first showing before a public audience of slides and moving pictures of the high-powered 14-in. navy guns with railway mount which were used effectively at the close of the war in breaking the line of communication with Metz. On Thursday evening Colonel James B. Dillard of the Ordnance Department reviewed the engineering features of heavy railway artillery of this and other countries. It is a pleasure to be able to publish liberal abstracts of all of these lectures in this number of THE JOURNAL.

Following the lecture on Thursday evening was the customary reunion and dance with refreshments, and an innovation was the decorating of the foyer floor of the Engineering Societies Building so that a social time could be in process in the large hall on this floor at the same time that dancing was in process on the fifth floor of the building, a feature that all seemed to appreciate.

PROFESSIONAL SESSIONS

Several months ago the Committee on Meetings and Program, sensing the spirit of the times in relation to labor problems, planned for a session to last throughout one day of the Annual Meeting on the human elements that enter into these problems. This session was introduced by Dr. L. S. Rowe, Assistant Secretary of the Treasury. He was followed by others who dealt with various phases of the employment question here at home. This session was attended by a large number, both morning and afternoon, and drew out a great deal of discussion. A brief account of the discussion is given in this number.

A strong session was arranged by the Sub-Committee on Machine-Shop Practice which accorded with the efforts put forth by the Society for the standardization of master gages by the Bureau of Standards as a central point during war production; and the appointment by the Department of Commerce of the Screw Thread Commission as a result of Congressional action. Papers were presented reviewing the work of standardization accomplished by the British Engineering Standards Association and of practice in this country of thread-gage making and testing. Exhibits of gage-testing apparatus were arranged in the building by the Bureau of Standards and by the Joint Gage Laboratories of the British War Mission and the U. S. Bureau of Aircraft Production.

A pleasing event was the joint session with the American Society of Refrigerating Engineers, to which both societies contributed papers in which a great deal of interest was evidenced.

As at the several recent annual meetings, the Sub-Committee on Textiles prepared a strong session covering problems that mill engineers have to deal with; and one paper in particular attracted considerable attention, outlining as it did the work of the Bureau of Standards in developing a cotton fabric for use as a covering for airplane wings in the place of linen.

A session which drew out a large amount of discussion was that at which the paper on the Weights and Measures of Latin America by Frederick A. Halsey was presented, followed by a paper on Efficiency and Democracy by H. L. Gantt.

On Friday morning, owing to the absence of several authors, the two sessions planned upon power-plant and general subjects were combined into one general session.

ADDRESS BY DR. GEORGE W. KIRCHWEY

The plan of a luncheon, followed by an address, inaugurated so successfully last year was carried out again, on Wednesday of the meeting, with an address by Dr. George W. Kirchwey, formerly Dean of the Columbia Law School, on A Message from the Legal Profession; or, as Dr. Kirchwey very modestly said, from "the profession which is concerned mostly with the past to the profession that looks mostly into the future." Dr. Kirchwey said in part:

"As I understand it now, you are passing through an enlarging experience. You are members of a profession by the same token that medicine and law are professions, by virtue of the fact that to your specialized technical training there is added a recognition of your social obligation to make that training available for the good of the larger community. That you are doing in a conspicuous degree, in a rather exceptional way as compared with other professions, because your work is primarily public work. You cannot if you would hide your light under a bushel as the parochial lawyer or the parochially minded doctor may easily do, because you are constructing works of public utility. Nevertheless, for the most part the work appears to the onlooker to be a series of jobs—a job performed for the owner who hires you whether he be Uncle Sam or a private employer. . . .

"It was due more to historic accident than anything else that the legal profession became a public institution; that there was committed to it the actual administration in the courts, and almost of necessity the actual work of amending and reframing the law in the legislatures and Congress. Thus the legal profession has been thrust forward into a position of vast public service, and therefore of public observation; and may I say generally of public appreciation? . . . .

"The doctor, too easily concealing his light under a bushel, has of late years also emerged from obscurity. It is because of recent discoveries in the field of science, the germ theory of disease, to lump it together into a phrase, and some of the larger applications, that the medical profession has suddenly been transformed from one rendering service to individuals to one rendering a wholesale service to the entire community. . . .

"I take it that the greatest achievements of the engineer are performed largely in the spirit that the lawyer argues his case in behalf of a public or private client, or the doctor treats his patients, doing it in the most genuine professional spirit, but falling short in utility to the community at large, that larger community service which the doctor is now performing and which the lawyer in his administration of justice is performing.

"Now," said the speaker, "I am going to invite you all to join the new society of engineers which I have decided since getting on my feet to create, the society of social engineers. You and a few lawyers are eligible (laughter). What I am getting at is this: that under conditions as they exist today no one can any longer wash his hands after the manner of Pilate and say, 'What is this to me? Go and deal with this case as you think best if you are interested. I am not.' That is no longer a tolerable attitude for any man who belongs to a profession and claims the dignity and the rewards that go with devotion to a profession. You have been dealing with material things and in the process have created new social problems. The enormous aggregation of men in our great cities, their congestion, has been due to the lines of transportation that you have set up and to the facilities for manufacturing that you have concentrated. You are responsible for this mess which we call modern civilization (laughter and applause) and it is up to you to get us out of that mess."

Referring to conditions of employment and labor he said there must somehow be devised by some engineering genius a method of stabilizing industry so that it shall no longer be subject to those extraordinary fluctuations which bring so much misery in their train and there must be devised some method of adjusting the relations between employer and employee so that they shall work together harmoniously to a common end.

Concluding Exercises

The Annual Meeting concluded on Friday morning with a brief service of a religious character, addressed by Rev. Edmund M. Wylie of Montclair, N. J., lately in charge of Y. M. C. A. work in Great Britain and who has visited the whole of the Western Front. At this time Dr. Hollis who was in the chair recalled that the concluding session of the previous Annual Meeting had ended in silent prayer that another year might find our boys on the way home after a glorious victory. This hope had been realized and it was only fitting that we should close this year's sessions by a few words from one of the returning soldiers, a soldier of the cross, who went to St. Mihiel with one of our divisions and was present at that great victory.

Rev. Mr. Wylie said that nothing had impressed him so much in the spirit of service which the world is learning anew as the work of the engineers. He instanced many cases of the boys at the front becoming enthusiastic about the preparatory work accomplished by the engineers, both at home and abroad. The most striking illustration was of the battle of St. Mihiel. The French had held the salient against the Germans for a few days at a cost of 14,000 lives. It was captured by the Germans; and in two days the French recaptured it and held it 40 minutes at a cost of 20,000 lives. Before the first American division made its charge the engineers had said, "You can take it with little loss of life if a certain plan is followed." The preparations were made and because of their thoroughness the Americans captured St. Mihiel with a loss of only 60 men in dead and wounded.

"So," he said, "I come back with Paul's idea, that he should make himself servant unto all men. I believe the engineer's idea is the democratizing of all service; to make oneself a servant unto all mankind. We have not only blown to pieces old dynasties but outworn creeds which have separated us (applause); and I have never known the world so united on essentials as now.

"I believe what I found characterizing the soldiers of the different nationalities properly characterizes the engineers. I have heard the British catch up their slogan, 'Carry on! Carry on!' I have stood in the valley of the Marne where Joffre stood when he said, 'Defenders of France we retreat no further, we die here.' I have stood on the heights of Verdun and have heard again the voice of Petain saying, 'Il ne passeront'—they shall not pass; and as I went down 150 miles of the lines occupied in part by the Americans I discovered not only 'Carry on!' but '*Carry through! Carry through!*' I am rejoiced to stand here, your prayer answered this day, to say that our boys are on their way home after the glorious victory."

ENGINEERING AND THE WAR

"I shall never forget the impression made on me by the late Lord Kitchener, the man who started the first movements in this great war, when he said—'Mr. Schwab, this is not a war of men; it is a war of machines, and the nation and the army that will supply the machinery of war will be the ones that will win this war, and the quicker and the more expeditiously the machinery of warfare is supplied, the quicker will this war be won.' How almost prophetic was that statement, as subsequent events developed its truth, because, after all, this war has been won for us by the splendid engineering and industrial talent of the United States."—Charles M. Schwab.

ENGINEERING IN THE PERIOD OF READJUSTMENT

"The future will have problems and trials. The contests will not be of battle, but of industry. The conquests will not be of territory or thrones, but of markets.

"Upon our ability to resume our normal lines will depend to a large degree our prosperity at home and trade expansion abroad. We were unprepared for war and it has been a stupendous task to readjust our industries to a war basis. It will be no easy task to readjust ourselves for peace. In this readjustment our vision must extend beyond the state and nation out into the broad world."—President Main.

OPENING SESSION, TUESDAY EVENING

Presidential Address on Broader Opportunities for the Engineer—Introduction of the President-Elect—Conferring of Honorary Membership on Charles M. Schwab and Orville Wright

THE opening session of the thirty-ninth Annual Meeting was held in the auditorium of the Engineering Societies Building on Tuesday evening, December 3, when Mr. Charles T. Main delivered his presidential address on Broader Opportunities for the Engineer to a large and appreciative audience. President Main's address dealt with the work of the Society during the year of his incumbency and in particular with the many war activities of the Society as a body and of the membership as individuals. A wealth of interesting facts was also brought out regarding the technical work conducted by the Society, and various national developments in which the engineering profession could be of assistance and guidance were pointed out, as well as important problems in economics to whose right solution the efforts of engineers should be directed during the coming days of reconstruction. The text of the address appears elsewhere in this issue.

At the close of President Main's address the Tellers of Election reported through the Secretary that the following officers of the Society had been elected for the coming year:

President:
MORTIMER E. COOLEY

Vice-Presidents:
F. R. LOW
HENRY B. SARGENT
JOHN A. STEVENS

Managers:
CHARLES L. NEWCOMB
F. O. WELLS
C. RUSS RICHARDS

Treasurer:
WILLIAM H. WILEY

President Main then introduced President-elect Mortimer E. Cooley in a few sentences recounting briefly his professional attainments, and as a teacher, administrator, successful engineer and one of the best types of public servants he prophesied for him unusual success in his relations with the membership.

PRESIDENT-ELECT COOLEY RESPONDS

President-elect Cooley, in responding, thanked the speaker for the sentiments he had expressed, and remarked on the tension under which he had been as the time approached for his assumption of the responsibilities of the high office to which he had been elected. He recalled the first meeting of the Society which he had attended—at Pittsburgh, in May 1881, where only 93 persons were present, contrasting it with the audience before him, and spoke of the impressions made on him by the men then active in the affairs of the Society, mentioning Professor Sweet, Dr. Brashear and Charles T. Porter by name. It would be his prayer that he might do what lay in his power to carry out the program outlined in President Main's address, which could not fail to constitute a high and memorable work in the reconstruction of this country if successfully done, as he was sure it could be.

BON VOYAGE TO PRESIDENT MAIN

At the conclusion of Dean Cooley's remarks, Past-President Ira N. Hollis arose and made a statement to the effect that a few weeks before M. Millerand, President of the French Engineering Congress, had invited the American Society of Civil Engineers to send to France a delegation of engineers to engage in reconstruction work in the devastated lands. With great generosity and kindness and that brotherly relation which it was hoped might always prevail between engineering societies, the Board of Direction of the American Society of Civil Engineers had decided that they ought to share this honor with other engineering societies, and thereupon had invited The American Society of Mechanical Engineers, the American Institute of Mining Engineers and the American Institute of Electrical Engineers to join them in this great work abroad.

The announcement he desired to make was that, through the good wishes and consent of the Council of the Society, President Main would represent the Society abroad.

"Happy is the man who has this opportunity," said Dr. Hollis, "and happy should the members of this Society be because they have so good a representative to send abroad to lend a hand to our little sister of nations on the other side who stood at Liège and turned back the German hordes that the land of freedom might be saved. Happy, too, is he who is able to extend assistance to France, the country that gave us our impulse toward democracy, by the Revolutionary War, and gave us help to end it, and end that kind of autocracy which never since has existed in Anglo-Saxon countries.

"I have risen here at the request of the Council to wish Mr. Main a splendid voyage to the other side, and that he may perform that kind of successful work that we are delighted to give to those who have saved for us and for all humanity the freedom of the individual." [Applause.]

CHARLES M. SCHWAB MADE AN HONORARY MEMBER

President Main voiced his deep appreciation of the good wishes expressed by the previous speaker, and then continued:

"It has been said many times that to win the war we must have the plants to manufacture the implements for the control of the sea and air. As soon as this country declared war there was started a gigantic program in shipbuilding—but under conditions which soon became impossible, and it was necessary for the President of the United States to select the greatest man in industrial affairs, who had the necessary knowledge, force and action, and put this man in charge, without restrictions, of this gigantic undertaking. This man he found in the person of Charles M. Schwab, and in some way persuaded him to undertake the work.

"Mr. Schwab has been honored by membership in many societies and industrial organizations in this country and in Europe, and it is our great privilege tonight to show him our appreciation of his engineering ability, keen judgment, boundless energy and great patriotism in assuming and carrying through the biggest shipbuilding plan ever undertaken, at a time when his services were also urgently needed by the Government.

"To give a little personal touch to this matter I have asked a dear old friend of Mr. Schwab, 'Uncle John' Brashear, to say a few words."

Dr. Brashear, in responding, began by stating that of all the degrees and titles he possessed, none was more highly prized by him than the one under which he had been introduced and which had been conferred upon him by his friend of many years, Mr. Schwab. He recalled many incidents of his long acquaintance with Mr. Schwab and cited numerous instances where he had shown his readiness to lend financial assistance for the furtherance of scientific projects.

"Among the men I have known who have been interested in science and engineering," continued Dr. Brashear, "are the many who had human hearts in them. Unless you have that human touch in your souls, unless that is back of your scientific work, all that you have accomplished will be less effective than if you had such impulses. [Applause.]

"Why has Mr. Schwab succeeded in his great work? Not because he was an engineer away above all the rest of his fellows, not because he had a reputation for his wonderful engineering work, great as it was, but because he had that something in his heart that won him favor among the people whom he met, and we delight to honor him because he has set us an example of the human side of engineering—an example worthy of being followed by every engineer.

It's the human touch in this world that counts
The touch of your hand and mine,
That counts far more to the sinking heart
Than shelter or bread or wine;

For shelter is gone, when the day is o'er
And bread lasts only a day,
But the touch of the hand and the sound of the voice
Live on in the soul alway.

"God Bless Uncle Charley." [Loud applause.]

President Main then formally conferred the Honorary Membership upon Mr. Schwab, who responded in part as follows:

Mr. Schwab's Acceptance of Honorary Membership

"First of all let me pay the tribute to my old friend 'Uncle John' Brashear that he deserves. I have known him since boyhood. I, like himself, have met many distinguished men in my life, and it has been a great pleasure to me to say publicly, and have it quoted all over the world, that of all the great men I have ever known I regard 'Uncle John' Brashear as the greatest of them all. [Applause.]

Charles M. Schwab

"I thank you sincerely, Mr. President, more sincerely than any words of mine may express for the honor that you have given me tonight. Very often it is the popular acclaim, many think, which makes a thing worth while having. A great scientific society like this is not usually swayed by any popular acclaim or theatrical performance or popular deed. There is nothing in life that one cherishes so much as the good opinion of the people who know him. It is not the great public reputation that brings satisfaction to the human heart of the men worth while, but it is the acclaim and approval of the people who have known him and have known what he has done, and there is no honor that I have ever received, and there is no acclaim to which my ears have ever listened, that will bring me a deeper sense of real satisfaction and pleasure than the approval of this great engineering society of the United States. [Loud applause.]

"There are some sounds that are very sweet to the ears of the real man: one of them, as I have stated, is the approval of those who know, the other is the approval of those with whom you work, and during this great undertaking, during our national crisis, an equally pleasing sound to my ears has been the sound of the workingmen throughout the shipyards and factories and engineering works of the United States when their voices above the din of the hammers could be heard saying—'We are with you, Charley; we are with you, Charley,' and I can assure you that every man, however high his station in life, will only give his best efforts under the approval of his fellow man and those with whom he is associated. [Loud applause.]

"Now I lay no claim to distinction as an engineer. I have spent my life in engineering projects—only the earlier part in actual engineering work and that long since forgotten—but I wonder if it has occurred to you that this great war for the freedom of the nations of the world and of our great and glorious nation, has been won by the work and influence of the engineers?

"I remember with much vivid distinctness my friendship for, and association with, the late Lord Kitchener, that great English general, the man who started the first movements in this great war. When I sat with him in his office and saw the look of responsibility that rested upon his face, this simple great soldier in plain suit of khaki, without any decorations, an impression was left that shall never be forgotten when he said—'Mr. Schwab, this is not a war of men, it is a war of machines, and the nation and the army that will supply the machinery of war will be the ones that will win this war, and the quicker and the more expeditiously the machinery of warfare is supplied, the quicker will this war be won.' How almost prophetic was that statement, as subsequent events developed its truth, because, after all, this war has been won for us by the splendid engineering and industrial talent of the United States.

"When I was asked to undertake the shipbuilding program, it seemed so prodigious in its requirements as to stagger the imagination, and I can assure you that after a week or ten days in touch with the project had given me a realization of what it meant, I would have given anything in the world to have been free of the responsibility that was placed upon me, when I saw the magnitude of what had to be accomplished. I feared at first that I should not have the responsibility and the right to do it in my own way, and it was not long until I feared the responsibility itself, and longed for the opportunity to share it with others.

"But I immediately found, as is always the case in a great emergency, that it was not a problem of the creation of machines and methods of doing things—that if it was to be done at all, it was to be done through what I called 'human engineering,' and that was the interest to the highest degree of the men in the shipyards who had to do the work. As a result of undertaking this work I went away from my office and everything connected with it, and spent ninety per cent of my time with the superintendents and the foremen and the workmen in the shipyards of the United States, and such a response as I received from every man connected with the industry is perhaps unparalleled in the history of any nation. [Applause.] I want to take this opportunity of saying that I know of not a single man in the whole shipbuilding fraternity—and there are 180 shipyards in existence in the United States—who is not fired with the spirit of intense enthusiasm and loyalty to plunge ahead and give the greatest possible effort, and during all that time there was never a single occasion when I was obliged or did say to any man connected with the industry—'You are not doing your best,' or 'You are not doing your duty.' [Applause.]

"The men at the head of that great enterprise were just as susceptible to the approval of the Director General and the American Nation as the workmen in the ranks were, and I have yet, as I said before, to find a man of high character, whether he be the King of England or the President of the United States, who is not pleased with the approval of the public in what he is doing. [Applause.]

"I must take this opportunity of paying a compliment to the workmen of the United States—I have never seen greater enthusiasm and greater effort upon the part of the workmen, indus-

trially, to win this war than I have found in the shipyards of the United States.

Our Accomplishments in Shipbuilding

"I must tell you briefly some of the accomplishments. The United States in no year prior to this war had ever constructed more than 400,000 deadweight tons of ships. General Goethals told me, when I started, that if the war continued on and during the year 1919 that 18 million tons of additional shipping to the world's then existing shipping would be necessary to maintain the armies in Europe, and that the plans for shipbuilding had to be on a basis that would give us at least 700,000 deadweight tons of ships for every month in the year 1919. It seemed a tremendous undertaking, but we continued to forge rapidly ahead until in the month of November, just ended, we placed in commission on the seas something over 500,000 deadweight tons of ships, and we will have placed in commission by the end of this year between 3,500,000 and 4,000,000 deadweight tons of shipping. [Applause.]

"When it was reported on the Fourth of July last that one hundred great ships throughout the United States had taken their plunge in the water, I felt that this war was won, because the workmen of the shipbuilding yards of the United States were going to their duty—and they have done their duty, and no credit should be given to the men at Washington like myself—I have always said that as long as I have a tongue to speak and ears to listen, I shall give the credit where credit is due. It is not the head man at Washington or at Philadelphia, the Director General or anybody else, to whom the credit for the successful accomplishments of this undertaking should be given—and if he had possessed all the talent and ability of the combined engineers in this great Society, he could not have accomplished it without the thoroughgoing and interested coöperation of every manager, superintendent and workman in the shipbuilding industry; and to them belongs the credit and let credit be given where credit is due. [Applause.]

"It has been a pleasure to be associated in such a great undertaking, to see its successful fruition and accomplishment, to have been a part of it, to have built ships to maintain our boys across the sea and carry them over. The real pleasure, however, is to build the ships and equip the ships to bring home those victorious boys of ours [applause], and when the history of this war is written it will not be the man who has built ships, it will not be the man who has invented and built airplanes, it will not be the men who have done all these things whose names will be written on the golden pages of this great epoch, but it will be, rightfully and honorably, the names of the boys who have made the supreme sacrifice on the battlefields of Flanders, that shall go down in the history and hearts of this great nation.

"I have been a fortunate man in my lifetime, in material things, health and friends, and one of the greatest pieces of good fortune in my business life was that I came to own and control one of the greatest ordnance works in the world, and that I could turn these works over for the use of our Government in the protection of this great country of ours, and I am proud of what it has accomplished, and I am sure you will not think I am boasting, but rather telling you something of interest in connection with this great industry at Bethlehem.

War Work of the Bethlehem Steel Company

"Since the beginning of the war the Bethlehem Steel Company has furnished the U. S. Navy with 60 per cent of all the steel for the ships and ammunition that they have received during the period of the war, and in addition to that it has furnished, besides the steel supplied to the Navy, one-quarter of all the steel for the merchant ships that have been built in the United States, and in addition to that we have furnished the Allies since the beginning of the war in Europe, and since the entry of the United States into the war, more than half of all the guns and munitions that went out of the United States or were furnished to our own nation. We have furnished to the Allies and to the U. S. Government more than 15,000 large field guns since the beginning of the war, or more than enough to furnish and arm all the soldiers of the United States sent to Europe. [Applause.]

"Now, I am sure that is a statement which will be of surprise to many of you people. I am proud of it, as proud of it as I could be of anything, because it was all in the nature of service to our country. I have reached the point in life, and all men reach it sooner or later, where there is nothing much left that brings real pleasure and excitement except the successful accomplishment of enterprising undertakings. And I do with pleasure and satisfaction dwell upon the work accomplished by our companies in this era that enabled the companies and the industries which I controlled to be so valuable in their service to this country at this time. In that I have been doubly fortunate. The next thing that I have been more than fortunate in, Mr. President, is to have had the approval of your Council and your members in the work which we have done. If it has reflected credit upon your Society and upon the members of the engineering profession, I am doubly happy and doubly grateful. [Applause.]

Orville Wright

"Mr. Wright is not going to speak this evening, so the less he says, the more honor you can give him. From the days of Darius Green down to a recent period, people have written and talked about the flying machine, but the Wright Brothers were the men who actually built the first successful machine and to them belongs the credit. [Applause.] And I feel that it is a proud thing to be recognized in the same manner and at the same time with a man like Orville Wright.

"I thank you for your warm, kindly welcome, and appreciate more than I can tell you the honor you have bestowed upon me; indeed, I can say I appreciate it more than any honor that has ever come to me. I shall appreciate it. This certificate of Honorary Membership which you have given me shall have a proud place in my household, and, what is more important, an imperishable place in my heart." [Loud applause.]

President Main then formally conferred the Honorary Membership upon Mr. Orville Wright, whereupon the meeting adjourned.

BROADER OPPORTUNITIES FOR THE ENGINEER

Presidential Address, 1918

BY CHARLES T. MAIN, BOSTON, MASS.

WE have probably witnessed the end of hostilities in the greatest conflict that the world has ever experienced. The people of this country, after some hesitation, undertook to assist in finishing the task which the Allies had begun at whatever cost or however long it might take.

It is now a time for great rejoicing, but the signing of the armistice is not the signing of the peace treaty. What kind of a peace we are to have will depend upon the wisdom with which the multitude of questions connected with the restoration and redistribution of territory and international relations are settled. The war will not be won satisfactorily unless the purposes for which it was fought, from our viewpoint, are assured.

At this time it may be well to recall why we have been at war.

President Wilson said, some time ago, "To make the world safe for democracy."

Lloyd George said, "We are fighting for a just and lasting peace."

Ex-President Taft said, "It is the struggle that is essential to liberty and Christian civilization."

Premier Clemenceau said, "Our victory and the victory of our allies means the liberation of civilization and liberty of human conscience."

Many other reasons have been and may be given why we were at war, but brought down to its final analysis, it is that this nation and other nations may live with the maximum of safety and with the greatest amount of liberty.

Probably most of us have a vague knowledge of the many issues involved and an indefinite conception as to the effect of the war on the political, social and business conditions of the world, but we can surely predict that there will be a remolding of all these so that our country will be one of greater unity of purpose and desire with a more spiritual and less materialistic view of life and greater unselfishness in the service of our country and mankind.

[President Main then reviewed the war activities of the Society, a brief statement of which has already gone to the membership in the brochure entitled "In the Service," and outlined the work of the Council and Committees for the year, which will be placed on record in the Transactions.—EDITOR.]

A BROADER VISION

With this review of what the men in our profession are doing in connection with the war and the collateral problems, also having in view the quick expansion and development of the work along comparatively narrow and restricted lines into circles of almost unlimited possibilities, we have seen how we can and must free ourselves from our former provincial attitude into one of universal outlook.

If this can be accomplished at this particular time and for this particular occasion, why should we not now and in the future exert our influence and direct our energies toward matters of broader interest?

As a class engineers have been extremely modest in their relations with business and public affairs. This has been a natural condition largely due to the education and training which they have received. The education has been along rather narrow and restricted lines of scientific work, leaving out almost entirely the broader studies of literature, common law, economics, business methods and the humanities. After graduation there is usually not much opportunity for broadening out, for it is necessary for a man, if he expects to keep abreast with the development of his profession, to spend nearly all of his surplus energy in reading and studying along the very lines which he followed in school.

Notwitstanding this, it is wise to carry along a course of reading on broadening subjects and to have an interest in affairs which are wholly outside the scientific line of study, and to be identified with engineering and scientific societies in order to get the broadest outlook of life possible. It is for this reason, in order to get a broader aspect of life and acquire a taste for wider reading and study, that it is of advantage for a young man who is to follow some scientific pursuit to take an academic course before he takes his scientific course.

I realize the impracticability for many men to spend so much time at considerable expense in preparation for their life work, but it is almost essential that a man should very early in his career acquire some knowledge of business principles and should endeavor to broaden himself so as to be able to fill with fair satisfaction the position that properly belongs to him in his profession and in the world.

It should be the aim of the engineer to render the best possible service considered in a broad sense. It should be based on facts and not theories or suppositions, and upon scientific laws, which if properly applied will give satisfactory results. Nothing should be taken for granted, and the work or statements of others should be carefully checked before being adopted.

The success of a man will depend upon his ability to produce results in an expeditious manner, which shall be accurate, and in which good judgment has been used, so that the finished product, if it be a physical structure, will be adapted to the use to which it is to be put and shall have been accomplished at a reasonable expenditure. If it be a plan for action it shall be clear and concise and adaptable to the purpose for which it is intended.

He should be able to understand men and to know them. He should be willing to share his knowledge with his fellow-engineers and inasmuch as he will do this through the Society, or other similar means, his interests and outlook will broaden and the return to him will be multiplied. Integrity and perseverance in work and business and fairness and justice to all will in the long run count for more than brilliancy in attainments. Withal he must have a good stock of imagination and judgment, which is sometimes called "horse sense" in the application of fundamental principles to every day problems.

The true success of a man is not measured by the accummulation of money, but by the success of accomplishment of work which adds something to the general good for mankind and for the advancement of the profession.

In his annual address President Hollis said:

> In the changes that are coming the engineer can no longer dwell within his technical shell, and he must prepare himself to become a citizen of the world, upon whose shoulders great economic and social burdens are placed.

And Professor Kimball has said:

> If we have not at this moment a clear vision of whither we are tending, now is the time of all times to take stock of ourselves and to redirect our course, whether this course is in conformity with time-honored definitions or not. Change is not necessarily synonymous with progress, but there is no progress without change. No one can doubt that the scientist and the engineer are to be the most important industrial figures of the near future. If we are faithful to our duties we shall be of greater importance politically and socially, but to accomplish this we must broaden our vision and get about our business, which is the industrial organization of our country.

Let us then bestir ourselves and show a greater interest and a broader vision of the opportunities which now lie before us and which will increase in number and importance in the near future.

IN THE PROFESSION IN GENERAL

We are living in a period of profound importance to the whole world. The social and political conditions and the ideals of some and perhaps nearly all the nations are in a state of flux. To a large extent this may be said of our own country. This state of uncertainty and uneasiness has overtaken many men in our own profession, and it seems, therefore, necessary for us to consider with great care if it will not be necessary in the near future to readjust ourselves to the new conditions.

There is a tendency to form new organizations to accomplish new objects, or with the hope of doing some things that the present organizations are doing in a better way. This is unfortunate, as it is unwise and inefficient to have so many agencies endeavoring to accomplish the same result. Consolidation rather than segregation, up to proper limits, is desirable.

In local communities some plan should be arranged, which would vary in different places, for the local organizations to combine on matters of common interest. The plan, however, is of less importance than the action itself. If the local societies and members of the same are active in service to the profession and to the community, a plan will be evolved by which these interests and activities can be made effective.

Organization

It was probably for this reason that the American Society of Civil Engineers, on June 18, 1918, created a Committee on Development and adopted resolutions creating the committee, a portion of which reads as follows:

> The development and application of the sciences in recent decades have caused profound changes in the social and industrial relationships of all peoples.
>
> Sociological and economic conditions are in a state of flux and are leading to new alinements of the elements of society.
>
> These new conditions are affecting deeply the profession of engineering in its services to society, in its varied relationships to communities and nations, and in its internal organization.
>
> A broad survey of the functions and purposes of the American Society of Civil Engineers is needed in order that an intelligent and effective readjustment may be accomplished so that the Society may take its proper place in the larger sphere of influence and usefulness now opening to the profession.
>
> Resolved, that a Committee be created to report on the purposes, field of work, scope of activity and usefulness, organization and methods of work of the American Society of Civil Engineers, and to make recommendations concerning these matters.

The purpose and scope of the work of the committee is thus in part defined:

> It is intended that the Committee on Development shall make a survey of the fields of usefulness which are or should be open to the Society, consider what functions may properly be assumed by the Society, define its purposes, formulate policies and methods of work to be recommended, and consider the needs in organization and constitution. This means taking stock and making plans. The resolutions contemplate an examination of present-day conditions and an outlook into the future. They involve considering the changing social and industrial relations of the times and the opportunities and responsibilities which devolve upon the Society and its membership. The relations of the Society to other societies and to the profession generally are also included. The outcome of the work of the Committee may be modifications in the activities, functions and methods of work, or in the emphasis in these matters, and possibly the addition of new ones.

Similar committees have been created by the American Institute of Electrical Engineers and proposed for the American Institute of Mining Engineers and our own Society. It is proposed that the various committees coöperate on subjects of common interest.

It is also suggested that it may be desirable to confer with representatives of local engineering societies throughout the country concerning the relations of such societies with the national societies.

The results of this work should be of great benefit to the whole profession in increasing solidarity, diminishing duplication of effort, more effective results in matters of common interest, a more representative opinion on subjects of general interest to the profession and public, the creation of a better feeling of fellowship and harmony and a much greater ability to assist in the inevitable evolution of industrial and social conditions which are soon to follow.

The advantages of unified command and action are most clearly demonstrated by the results obtained by the Allied armies under the supreme command of General Foch.

The Engineering Council is a step in the direction of coördinating the work which is of common interest to the profession. It has done much good work, but has not yet reached the maximum of its usefulness.

Within Our Own Society

In anticipation of the work of our Committee on Aims and Organization, there may be mentioned some details of operation in the minor workings of the Society which might be broadened to advantage.

A plan might be developed for increasing the financial resources of the Society by contributions or legacies to a fund, the income of which could be devoted to research work and for prizes and premiums to the younger members for good work and for any other meritorious object which might present itself.

A plan should be developed which will make a working connection between the general meetings and the local meetings.

The coöperation between the Publication and the Local Sections Committees can be greatly developed if the individual members will see the great opportunity which these committees have already provided in the equal status of papers read before local and general meetings of the Society. The members can further help the Publication Committee in conjunction with the Meetings Committee by an earlier announcement of prospective papers, so that a general program for the ensuing year can be prepared during the summer and be submitted to all of the local sections and coöperation solicited in carrying such a program to completion.

During recent years the increased responsibility placed upon young men has increased the difficulties of the Membership Committee in the proper grading of applicants for membership. It may be that the Committee on Aims and Organization could well give consideration to this matter.

As already indicated, another profitable investigation which the Society can undertake is a still closer relation between the Research Committee and our other committees, including the Engineering Foundation, with the industries and with the scientific schools having facilities for research work. It has been suggested that the Society act as a clearing house between the research facilities of the universities and the research requirements of the industries.

Most of the broader aspects within the Society are in line of extending the usefulness of any one activity through the medium of coördinating it with some other activity. The whole organization is capable of being rounded out and planned so as to produce the maximum of teamwork.

Consolidation of Technical Societies

In the Monthly Bulletin of the American Institute of Mining Engineers, March 1918, there appeared the following:

> The vision dwells in the minds of many that ultimately these four great societies, lightening the emphasis they place upon their differences, may see the time when, for the solidarity of the profession, for their best interests, as well as for increase of their influence on the country at large, they may become one great national association of engineers. With the gain in power and prestige inevitably following such an aggregation, freedom for individual development may be achieved through divisions along the lines of technical interests, which might either follow the present four grand divisions or be more minutely subdivided.
>
> An organization of this sort could and probably would be more strictly professional than any of the four have been hertofore, and through the prestige and power of its numbers could establish standards of ethical conduct for its members, violation of which would bring grave consequence.

This great vision is worthy of the most careful consideration and might be carried with safety to a point where the national societies would be gathered in under one executive head, without any one losing any vital portion of its individuality.

This would be a great step in advance and perhaps as far as we should go for some time to come.

Standardization

There is now opening up to the profession the most promising opportunity of furthering the work of national and international standardization. It is the beginning of a real great international movement for standardization.

All of our own standards committees are working under the general direction of the Standardization Committee, the sole duty of which committee is to see that the work of the various committees shall be in harmony with the general scheme, but not to prepare standards for any particular purpose.

The American Engineering Standards Committee has been

created for the purpose of harmonizing the standards of the various branches of the profession, and it is about ready to function.

Upon invitation of the British Engineering Standards Association, this Society is acting as an informal correspondence committee in the United States.

National Developments in Which the Profession Can Be of Assistance and Guidance

Although the military conditions with the Allies in Europe are satisfactory, there is a vast amount of work yet to be done in clearing up the whole situation, and our efforts should not be diminished until a satisfactory ending is reached.

It is now time to give careful consideration to the readjustment after the war, so that this country shall maintain its national and industrial integrity with due regard to our obligations to other countries. We were unprepared for war, which was a possibility, and we are unprepared for peace, which is a certainty.

The future will have problems and trials. The contests will not be of battle but of industry. The conquests will not be of territory or thrones but of markets.

Plans have been under consideration for some time in England, France and Germany for regaining the commerce lost during the war.

Upon our ability to resume our normal lines will depend to a large degree our prosperity at home and trade expansion abroad.

We were unprepared for war, and it has been a stupendous task to readjust our industries to a war basis. It will be no easy task to readjust ourselves for peace. In this readjustment our vision must extend beyond the state and nation out into the broad world.

"With courage we must face the future, confident that with a better understanding of our local and national problems, and with a closer and more systematic coöperation between the governing authorities and business institutions, continuing progress will be assured. These are not times for jealousies, prejudices and selfishness, but with a largeness of heart and bigness of vision we must unite in a common effort to help America achieve its manifest destiny."

Bills have already been presented to Congress which contemplate the creation of a Federal Commission on Reconstruction, the duties of which are far reaching. The Commission is to investigate and recommend to Congress what additional legislation or changes in legislation are desirable.

Under the Weeks' Bill the subjects are summarized as follows:

1 Problems affecting labor
2 Problems affecting capital and credit
3 Problems affecting public utilities
4 Problems resulting from the demobilization of our industrial and military war resources
5 Problems affecting our foreign trade
6 Problems affecting the continuance of existing industries and the establishment of new industries
7 Problems relating to agriculture
8 Problems affecting the adequate production and effective distribution of coal, gasoline, and other fuels
9 Problems relating to shipping, including shipyards, and especially in regard to the sale, continuance of ownership, or leasing of both yards and ships
10 Housing conditions and the disposition of houses constructed by the Government during the war
11 War legislation now on the statute books, with reference to its repeal, extension, or amendment
12 And in general all matters necessarily arising during the change from the activities of war to the pursuits of peace, including those that may be referred to it by the Senate or House of Representatives.

Under the Overman Bill the tasks named are as follows:

a The financing, regulation, control, and development of the merchant marine
b The development, financing, expansion, and direction of foreign trade
c The reorganization, financing, and readjustment of industries engaged in war work by way of reconverting them to normal production
d Technical education and industrial research as a means of developing and strengthening industry
e The redistribution and employment of labor in agricultural and industrial pursuits and the problems of labor growing out of demobilization
f The supply, distribution, and availability of raw materials and foodstuffs
g The conservation and development of national resources
h Inland transportation by rail and water
i The reorganiation of government departments, bureaus, commissions or offices with a view to putting the Government on an economical and efficient peace basis
k The consolidation of such acts and parts of acts of Congress which relate to the same subject-matter, but which now appear at various places in the statutes.

Nearly all of the problems suggested above are directly or indirectly engineering problems. The framing of laws would be greatly facilitated if the advice of the engineers were made available in furnishing many of the physical and technical facts upon which they should be based.

Nearly all of the problems of a municipality and largely of the state and nation are engineering in their nature and it should be the duty of all engineers to take an active interest in the conduct of public affairs in so far as the opportunity offers. It is always possible in the smaller way in the community and the opportunity will broaden if a man shows his ability and interest into fields of wider scope.

Our assistance will be needed now more than ever, for the tendency of the times is toward socialism and government ownership or control of all facilities which are used by the public. The arm of federal authority is reaching further and further into our personal life and affairs. We are moving rapidly in the transfer of authority from those who have a personal interest in its successful exercise to those who have only political advantage to gain.

This Society, other societies and Engineering Council are already working on some of the problems. We are not concerned with all of them at present, but should be soon. We should begin to look upon all of them with a broader vision, and should take a more active and helpful attitude toward public affairs and industrial relations which we have heretofore considered beyond the scope of our work.

One of the reasons why we have not accomplished more during the war has been the difficulty of making a definite connection or association with the military operations of the Government. It has been suggested that some arrangement might be made between the Government and Engineering Council, by which all kinds of engineering and kindred problems could be submitted to the Council. It is also suggested that Engineering Council offer its services to every Congressional Committee having problems of an engineering nature to report upon. If it could be brought about that the engineers would be invited to assist, it would be a very satisfactory arrangement.

There will probably be many commissions established on which an engineer member would be of great assistance in transmitting to the other members such technical information as they would need to understand the fundamentals of the technical portion of the problem and in directing the line of effort for obtaining the technical data required.

Before we can make a successful connection, however, we must have enough knowledge of their problems and enough imagination to be able to suggest along what lines we can be of assistance.

While we are holding our convention, the National Council of the Chamber of Commerce of the United States is being held in Atlantic City, for the purpose of formulating plans for reconstruction of business.

Readjustment of Labor and Treatment of Employees

Probably the greatest problem before the nation is the redistribution and readjustment of labor.

The following is quoted from a bulletin of the Chamber of Commerce of the United States with reference to "A New Service."

War conditions impose upon business and industry problems of great difficulty and unusualness, requiring thought and action.

The conditions of shortage of labor, the great pressure of demand for products, the shrinkage in the purchasing value of the wage, and the spread of democratic ideas have created the necessity for labor administration all along the line from the Government down to the small private manufacturers.

These developments have all come about so rapidly that their implications and necessary consequences have not been realized. The most far-sighted and intelligent opinion sees in these events the beginnings of revolutionary changes in industrial relations which will eventuate in a strong federal labor administration to control this vast machinery.

The employers have an unlimited opportunity at the very beginning to participate in this administration. The danger of failure is greatest from indifference and lack of understanding among employers, from an unwillingness or incapacity to learn coöperative in place of competitive methods.

The War Service Committees, under the direction of the Chamber, are working out adjustments called for by the War Industries Board as regards materials, fuel and transportation. The Committee on Industrial Relations has undertaken similarly to join with the War Labor Administration in its task of procuring the maximum utilization of our labor resources.

To investigate all experiments and developments in industrial relations both in this country and abroad and to place before the membership the results of such research. To assist the constituency of the Chamber in bettering the relationship between employer and employee by making available the records of the best experience and practice concerning wage and hours adjustment; methods of handling grievances and discipline, industrial service (improving the working and living conditions of employees and their families, housing, medical service, recreation, insurance, accident prevention, etc.); dealing with labor organizations; utilizing mediation and arbitration in disputes; securing the coöperation of employees in raising standards of efficiency; improved methods of employment management, hiring, transfer and dismissal, fitting the men to the job.

The permanent results of the activities of this committee will be educational. If successful, it will have created in the minds of employers a rational attitude, supported by facts and information, concerning the relations between themselves and those whose interests they are administering. The wage earner is just as dependent upon the intelligent and successful administration of enterprise as is the business upon the loyal and efficient service of the employees. The war has given an impetus toward democratic methods of administration both in public and private enterprise. Industrial administration must adapt itself to those conditions and conform to the prevailing ideas of the time or find itself in antagonistic relationships with all interests with whom it must deal. The employer must conceive himself to be a trustee of the interests of all involved in his enterprise and see that these interests are properly represented, lest he be confronted with opposition handicapping all his efforts. These administrative difficulties are not wholly the product of war nor will they disappear at the close of the war; indeed, it is more likely the industrial problems will increase in complexity with the coming of peace.

These quotations have been made because they describe the problems and responsibilities which are ours.

This vast and wonderful industrial organization with which we are living and struggling, is the growth of the last century. Its growth has been so rapid that neither the employer nor employee as a whole has been able to see with clear vision a just solution of the many problems of relationship one to the other. For this reason there have been misunderstandings and struggles of great intensity with the tendency of further separating the two parties, whose interests are largely in common. Protective organizations have been formed principally by the employees, whose object is primarily the betterment of the condition of the working people. Just so long as these organizations representing the employer and employee are managed and conducted for the general welfare of the community as a whole, they may be of service to the country, but when their affairs are conducted in a manner prejudicial to the interests of the community, they should be curbed.

Organized labor has its plans for the present and after-the-war period, which from all indications are very far reaching. The industries may have some plans, but they are not much in evidence.

The real issue is whether the genius of American individual enterprise is to be free, with due regard for the opportunity and welfare of all the people. The responsibility of guiding the republic rests upon such thinking men and men of experience as are members of this Society.

Many of our members are now vitally interested as employees with these great relationship problems. Some of those who are now employees will later be advanced to the position of employer, and knowledge of these problems will better fit them for advancement. By treating this matter on a very broad basis far greater progress will be made toward the establishment of satisfactory conditions than by settling down into a condition of stubbornness and refusing to look the facts in the face and endeavoring to operate under conditions which may be wholly in opposition to preconceived ideas of what is proper.

We had our labor problems before the war, they will be more complex after the war, on account of the readjustment which must take place. The bulk of the men who have gone into the service will return, many women have gone into the industries and into work heretofore done by men only, and in many instances they have surpassed all expectations. The policy to be followed by foreign countries to regain their lost or impaired commerce will have a bearing on our problems.

These and many other questions will tend to make this problem more complex.

It is hoped that as a result of this war there may be greater efficiency in industry, a better use of the productive potentialities of men and materials, more perfect business organizations, elimination of waste, the doing away with many non-essentials and extravagances, but no amount of organization, standardization and control will be of any consequence in increasing production, unless the workmen concerned will put forth the requisite effort, and unless labor stands for increased rather than decreased production, this country is on the way to industrial ruin.

As business men, employees and employers, we can individually bring influence to bear toward a fairly just and satisfactory treatment and solution of these problems, and as professional men, without prejudice, we should be qualified to discuss with impartiality these problems and act as arbiters in the settlement of many questions of doubt.

The real and great problem extends far beyond the adjustment after the war. It means the development of relationships which will enable all of our citizens to live and work together under conditions which will produce the maximum amount of happiness and contentment possible for years to come.

It is perhaps nothing more than a dream of De Constant, the realization of which is far in the future, but if we all think and work along lines which will lead up to its accomplishment, it will be aproached as years go by.

"The spirit of domination will lose more and more its prestige, while a policy of justice and conciliation will impose itself as being the only one corresponding to the aspirations and progress of humanity." (De Constant's America and Her Problems.)

Education

Another one of the most important problems in which the Society could be of great assistance is education.

The Council of this Society has been acting upon the assumption that the war may last for several years and that it would be a calamity to withdraw from our colleges and scientific schools all of the raw material for immediate use in the field, unless the crisis becomes more acute than it has yet been, but that this material should be retained for training in order to supply the loss of men which will occur if the war should go on for some years and the increased need of men trained in the sciences and industries. It petitioned Congress to enact such legislation as would enable drafted men to be assigned to special study or work and not to be called into active service until they have been fitted for the work which they can do best, unless it is absolutely necessary to have immediately a vast amount of man power in the field.

The resolutions called for "Maintaining unimpaired the engineering strength of the nation for the prosecution of military operations and for the support of the sustaining industries."

"It urges that schools of engineering as the principal sources of this training be regarded as closely allied in the material purpose with military and naval schools of the nation."

Copies of the resolutions were sent to the Secretary of War and the Provost Marshal.

A committee was appointed to ascertain the availability of technical schools and laboratories and what other opportunities there may be for industrial training.

Resolutions were passed and sent to the Secretary of War, protesting against the diversion of engineering schools from their primary function of advanced technical education, because of the persistent pressure for a training of technicians for the war.

As a result of these resolutions the Secretary of War appointed a Committee on Education and Special Training. Another result was the nationalization of scientific schools and colleges.

Committees of various kinds have been created for directing the work of special education and training for the war, but very little actual work has been done with reference to education after the war.

Bills have been passed in Congress making substantial sums available for vocational education upon joint action of the states with an equal appropriation of the allotment to the state.

If the manufacturers of the country desire to utilize this fund, it is up to them to secure the assistance of the state; otherwise the fund or that apportionment for the state not taking advanage of the opportunity will be turned back into the Treasury.

The Federal Board for Vocational Education has undertaken the work of reëducating disabled soldiers and sailors. It has made the following statement:

> In dealing with the disabled man, the Board expects to treat him throughout as a civilian needing advice and assistance, to approve his choice of occupation, unless, after careful investigation, sound opinion shows it to be in the end not advisable to train him to meet the needs of the occupation he has selected, to urge him to make the most of his opportunity to overcome his handicap by taking thoroughgoing instructions, to help him to secure desirable permanent employment, and to keep in close touch with him after he goes to work.
>
> The manufacturer should be greatly interested in this work of rehabilitation and should aid the Board in every possible way. The War Department expects to train a large number before the year is out.
>
> These reëducated men, made proficient in some trade or operation suited to their remaining capabilities, are going to constitute the most available source of skilled labor for some time to come. They will probably be the most dependable labor in the inevitable period of unrest and readjustment after the demobilization of the armies, when the country is settling back into a normal condition again. These reëducated men will form a core around which the newer labor can center. The manufacturer who has the foresight to make liberal use of these trained men is going to have an immeasurable advantage over his competitor who trusts to luck to get the help he needs out of the disbanding armies.

Very little, other than that already described, has been done with reference to education after the war. This work should be begun immediaately. Plans should be made for reconverting the scientific schools and colleges back to their peace program.

Many of our members are engaged in manufacturing and many in teaching. We have committees on Industrial and Vocational Training. There should be coöperation between the industrial plants and the schools. We can be of great assistance in the practical redevelopment of the educational systems and in the relationship between the schools and the industries, in the rehabilitation of crippled soldiers and industrial workers and the teaching of the blind, in an endeavor that every man shall have an opportunity to earn a living in a way that will carry with it some deegree of happiness.

A portion of a recent editorial in London *Engineering* reads as follows:

> Education in its broader sense should have as its main object the training of the mind towards the achievement of greater happiness and this can only be got by developing the thinking faculty so that a better perspective of life can be obtained. Thereon rests the hope for greater amity between employer and worker and a higher realization of the duties of citizenship.

The recent report by Dr. Charles R. Mann, entitled A Study of Engineering Education, prepared for the joint committee on engineering education of the National Engineering Societies, Bulletin No. 11 of the Carnegie Foundation for the Advancement of Teaching, should be read by everyone who is interested in engineering education.

The report should be of great assistance in the reorganization period. I am in accord with many of the recommendations and conclusions, particularly those mentioned in the introduction by the Joint Committee on Engineering Education, which reads as follows:

> Other significant characteristics of the report are found in the discussions of the general failure to recognize such factors as "values and cost," the importance of teaching technical subjects so as to develop character, the necessity for laboratory and industrial training throughout the courses, and the use of good English.
>
> Another point emphasized, and one of deep importance, is that of the reorganization of curricula which are commonly acknowledged to be much congested, and which it is stated will continue, "as long as departments are allowed to act as sole arbiters of the content of the courses." Plans are offered for developing particular types of curricula suited to the environment of each school.
>
> Emphasis is also given to the necessity for a broader training in the fundamentals of science as an equipment for all engineers and forming a sort of "common core" to every curriculum. With this broad training in the first and second years the student is expected to develop some natural leaning toward a specialty, and then will follow vocational guidance in the later stages of his education.

The scale for measuring the success or failure to provide proper training for engineers has been created by the practicing engineers. That scale is the improvement of character, resourcefulness, judgment, efficiency, understanding of men, and last of all, technique, as shown by students.

With the conversion of the schools and colleges to war work, intensive study became necessary. Everything except the essentials was eliminated, with more hours of work per year.

It would be a good thing if in the reorganization period much of the specialization work can be eliminated and thus a shorter time be required for college work for the bulk of the students, and if a greater portion of the year could be devoted to work, thus using the educational plants to a higher degree of efficiency, that is, with a higher load curve.

In educational, as well as in other lines of endeavor, if we have not learned a lesson of conservation of time and effort, we shall have missed some of the benefits which it is hoped will be derived from the war.

Conservation

Next in order of importance to labor in the industries is the ability to procure raw materials in sufficient quantities and at reasonable prices. I will not dwell upon this subject, but will pass to the question of power, with which we are more closely identified, and which affects directly the bulk of our people.

Many of our members have been assisting in the conservation of fuel by serving on committees or individually in attempting to assist the various fuel administrators in the country, or on committees or commissions established for the proper development and utilization of our water resources.

Considerable savings in fuel have been effected recently by more careful attention to the burning of fuel and the use of steam in prime movers, but much more has been saved in simple commonplace and common-sense ways of preventing the waste of heat and power after they have been delivered from the boiler and engine rooms to the various rooms and departments about the plant.

An example of the sort of work which the engineers can accomplish in fuel conservation is that done by the Advisory Engineering Committee to the Fuel Administrator of Massachusetts, all of the members of which, with one exception, are members of this Society, in the assisting in the establishment in every plant and building using steam for heating and power, of a fuel and power committee within its own organization, whose duties are:

1 To see that fuel is burned economically and to prevent waste of steam and power
2 To initiate and carry on a campaign of education among fuel and power users
3 To distribute among users, engineers and firemen an outline of the items of loss, and to supply information for the purpose of saving fuel and power
4 To assist local fuel committees in enforcing economies in wasteful plants

5 To enlist the services of engineers in carrying out this program.

Similar work has been done by other committees in many states.

During this work, however, we have been endeavoring to get the best results with the existing facilities. We should now be studying the vaster problems which are to be undertaken in the future for the conservation of our natural resources.

The generation and transmission of energy by electricity has changed the conditions so radically in the last few years as to require the most careful study of the proper place and manner of the production of power for all purposes.

The problem of power supply is very intimately connected with the railroad and transportation problems, and a study of one involves the study of both.

There have been very serious delays in the transportation of materials and supplies, and one of the principal reasons for coal shortage last winter was a lack of sufficient transportation facilities. It is stated that about one-quarter of all the coal used and transported is for the use of the railroads, and another large portion is required for manufacturing, lighting and power. Some of this necessarily must be used at the plants for heating and manufacturing purposes.

Much of this traffic could be eliminated by the establishment of large steam-generating plants located as near the coal mines as conditions will permit, and on tide water, where coal and oil could be brought in by vessels, by the development of hydro-electric powers, which are within reasonable distance of the market, and by the electrification of the railroads, with great trunk connecting and transmission lines. Incidentally with the further development of hydro-electric power is the saving in labor required for the mining, transportation and burning of coal.

Savings can be made by more careful study and use of the waste heat of furnaces in the form of gas for the production of power, and from steam turbines and engines by the use of steam and warm water for heating and manufacturing purposes.

Further conservation of power and fuel can be made by interconnecting transmission line between the hydroelectric companies so that the greatest possible use could be made under the varying conditions of flow of the steam at the different developments.

Still further saving of fuel can be made by the redevelopment of many of the older water-power plants, which contain inefficient wheels in efficient settings, and it may be possible in many cases to increase the capacity of the plant so as to use all of the water for a longer period of the year and waste water for a shorter period.

The conservation of flood waters, now wasting, by the construction of storage reservoirs, is receiving greater consideration. Special commissions have been appointed in some states for the study of this question, but as yet no great progress has been made so far as reservoirs for power are concerned. Most of the reservoirs for power already constructed have been built by private interests and by agreements among parties deriving benefit from such reservoirs.

The four chief reasons why this sort of development has not proceeded more rapidly are that the development expense and yearly charges of many would be so great that the returns would be insufficient to offset them and show a fair return on the investment, the inability of parties at interest to agree on some working plan for sharing the expense, that legislation has been of a discouraging nature, and because in the past all values have been measured in dollars and cents, as applied to the cost of power with not much consideration to conservation or the uses to which the power was put.

The expense of such large developments at the mouth of the mines and at tidewater, and of the development of some of the hydroelectric powers, may be too great for private interests to undertake. The uncertainties and restrictions imposed have been such as to prevent the development of some of the possible water powers. More liberal legislation is needed to encourage these undertakings in many of which the margin of profit is small and doubtful. Congress has now under consideration a water-power bill which it is hoped will encourage developments.

From now on we should consider the value of development with a broader conception of not only the net comparative cost of power, as produced by one means or another, but also in connection with the desirability of having another instrument by which the full production is assured, the value of the product being far greater in most cases than the cost of power, and with the desire to conserve our natural resources, and with a view in times of shortage, of assisting in the general stabilization of business.

It is not conceivable, however, that the business men will be willing to make expenditures for anything that will not improve their own property or conditions, and any excess expenditure required for conservation for the benefit of the general public must be met from the treasury of the public. It is conceivable and proper, however, that the individual should take a broader view of the benefits to be derived from expenditures for his own benefit.

The basis for valuations of all properties or undertakings while subject to discussion and variation of opinion, was fairly recognized three or four years ago. Estimates of initial cost, cost of operation, gross and net income were made to determine the value on a basis of dollars and cents.

During a period of war, costs and values were increased enormously, and values are not measured in dollars but in time, necessity and quick availability for the purpose of ultimately saving life and vaster amounts of property and even the safety of the nation.

After the war there must be a readjustment of values, and with this there should be a broader conception of values than that measured wholly in net returns of money.

The above outline of possible methods which might be used for the conservation of fuel is made for the purpose of describing in a general way the broader view which should be taken of this particular subject, and as an example of how the many other problems which have been summarized earlier should be attacked, not as a problem by itself to be decided in terms of money as applied directly to that particular problem, but with careful consideration of the broader bearing upon the greatest good for the community or country. Such broad consideration as this will necessitate a remolding of our former circumscribed conceptions, a broadening of our imagination and the weighing of the effect of action and consequences in the broadest and most liberal manner.

As a people we should readjust our methods of life, getting down more nearly to the fundamentals, eliminating many extravagances and wastes in our private method of living, in our local, state and national governments, in education, in the industries and in all of our activities, so that we may not rob future generations of the heritage which is rightfully theirs, and so that we, ourselves, may by elimination of many cumbersome things, get a better perspective of what is necessary and right and live with a better conception of the real things of value on this earth. If we shall not have learned a lesson which will enable us to do so, a part of our suffering will have been in vain.

In closing I desire to quote from an article prepared by Hon. Joseph I. France, which is applicable to the present time and during the period of reconstruction:

"Scholars and members of these great academies, officials of states and nations, men in the armies, men and women in all our industries and at home, must catch a vision of this process and of this plan and strike strong, increasing, shaping, fabricating blows in order that in these fires American may be welded into that new and more nearly perfect symmetry and unity which will assure to each and to all the utmost safety and the highest liberty.

"In America the new temple of liberty is not yet builded, but it is in the building, and it is for us, for each living American, an hour of opportunity and of destiny, in which we all must rededicate ourselves unreserved to sacrifice, to toil and to unwearying service until the nobler and more lofty fane is fully complete."

AIMS AND ORGANIZATION OF THE SOCIETY

Progress Report of the New Committee on Aims and Organization of the Society, Presented by Mr. L. C. Marburg, Chairman, at the Thirty-ninth Annual Meeting

THE Committee on Aims and Organization convened for its initial meeting on Monday, December 2, when the following were present: Representing the Local Sections—Earl F. Scott, Atlanta; Charles H. Repath, Los Angeles; C. H. Bierbaum, Buffalo; E. S. Carman, Cleveland; Ralph Collamore, Detroit; A. G. Duncan, Boston; John T. Faig, Cincinnati; Howard Gassman, Birmingham; Howard Gustafson, St. Louis; J. L. Henning, New Orleans; C. E. Lord, Chicago; L. V. Ludy, Indianapolis; T. C. McBride, Philadelphia; G. K. Parsons, New York; H. P. Fairfield, Worcester; C. M. Spalding, Erie; L. H. Strothman, Milwaukee; C. W. Tubby, Minnesota; A. E. Walden, Baltimore, and Robert Sibley, San Francisco. Members at Large—L. C. Marburg, Sumner B. Ely, W. F. M. Goss, L. P. Alford, Dexter S. Kimball, F. R. Low and James Hartness.

The program reproduced in the center of the page was discussed, and the proceedings of the meeting are described in the following report by Mr. L. C. Marburg, Chairman, which was delivered at the business meeting of the Society, held in the Auditorium of the Engineering Societies Building on December 4:

Committee on Aims and Organization

PROGRAM OF FIRST MEETING

December 2 to 4, 1918

A. RELATIONS OF THE MECHANICAL ENGINEER TO HIS WORK.

Note—Here should be classed all activities of the Society to be undertaken for the benefit of mechanical engineers, either individually or as a group.

1 Discussion, Recording and Dissemination of the Progress in the Art of Mechanical Engineering and Allied Sciences.
2 Conducting and Assisting Research.
3 Standardization.
4 Industrial Management.
5 Education and Special Training.
6 Legislation and Jurisdiction affecting Engineering Profession.
7 Engineering Societies' Employment Office.
8 Code of Ethics.
9 Other subjects that suggest themselves.

B. RELATIONS OF THE (MECHANICAL) ENGINEER TO THE COMMUNITY.

Note—These relations identical in principle with the relations of other engineers to the community. Here should be discussed the engineering profession's opportunity to render service to the community.

Ba. IN CONNECTION WITH LEGISLATION.
1 Protection of Health, Life and Comfort.
2 Production, Distribution and Sale of Commodities and Service (exclusive of "Public Service").
3 Industries, Utilities and Natural Resources, Owned or Controlled by Communities.
4 Legislative Changes to Secure for the Engineer Influence in Public Affairs.
5 Other subjects that suggest themselves.

Bb. IN CONNECTION WITH ADMINISTRATION.
1 Placing Engineers in Public Positions requiring Engineering Training.
2 Coöperation with Engineers in Public Positions.
3 Creation of Special Organizations in Times of Emergency.
4 Other subjects that suggest themselves.

Bc. IN CONNECTION WITH JURISDICTION.
1 Assistance in Enforcing Legislation as mentioned under *Ba*, by obtaining action against violators and helping in the securement of expert testimony.
2 Assistance in the Settlement of Disputes.
3 Other subjects that suggest themselves.

Bd. IN CONNECTION WITH PUBLIC OPINION.

C. RELATIONS OF THE MECHANICAL ENGINEER TO OTHER ENGINEERS.

Note—Under this heading should be discussed the organization of the Engineering Profession.

1 Advantages of Closer Relations.
2 Form of Closer Relations (Organization).
3 Internal Organization of the A. S. M. E.
4 Other subjects that suggest themselves.

PROGRESS REPORT OF THE COMMITTEE

At our Spring Meeting at Worcester last May, a resolution was passed expressing the opinion that the activities of The American Society of Mechanical Engineers, as demonstrated in meetings and literature, were not in harmony with the aims and purposes of the Society as expressed in the Constitution, and suggesting to the Council to take some action to have the aims and purposes of the Society restated.

Closely upon this resolution at Worcester followed the memorable resolutions of the American Society of Civil Engineers, passed by the Board of Direction on June 18 of this year, creating a Committee on Development. Extremely well they state in their preamble the considerations which make a broad survey of aims and purposes advisable. Let me quote:

> The development and application of the sciences in recent decades have caused profound changes in the social and industrial relationships of all peoples.
> The Engineer has been a leader in this progress.
> Sociological and economic conditions are in a state of flux and leading to new alinements of the elements of society.
> These new conditions are affecting deeply the profession of engineering in its services to society, in its varied relationships to communities and nations, and in its internal organization.

These are days of change; indeed, days of revolution. Overwhelming, unbelievable are the transformations taking place. Empires have fallen almost between two succeeding editions of the same afternoon paper. Only a few years ago individualism

reigned supreme in the business and life of our country; these last few months we have had our breakfasts and our dinners regulated; have been told when we may drive our automobiles, and what not. And then our railroads, our telephones and telegraphs, our express companies are operated by our Government. True enough, it has all happened under the exigencies of war; but who will say how far we will go back in times of peace? Revolutions we have witnessed and are witnessing; but not only political, economic and social revolutions; revolution even more in our habits of thought and our ideas as to the necessity of preserving the past. While we are casting off long-cherished methods of conducting the country's everyday life, we are challenging conventional ideas and preconceptions, we doubt theories held almost sacred heretofore, and we freely question not only the views of others but our own. A momentum has been acquired by this habit of thought which will carry us, if we but guide it wisely, far into the promised land of economic efficiency and social justice; not to the millennium, I am sure, but to institutions based on modern thought and present-day development instead of on conditions and beliefs a century ago.

What Is the Engineer's Part?

But dreams do not come true unless we work for them. What, then, is the engineer's part in carrying this dream to reality? What is and what should be the position of the engineer today? Look about you. You see a world on which, during the past two generations, the engineering profession has placed a stamp more marked than any other group of men, but in the management of which it plays a rather secondary part. There is an abundance of public work and public business which is of a nature familiar to the engineer and similar to the tasks he performs in his everyday activity. Much of this public work is done in such a way that no private industry or institution could copy it without fiasco, financially and otherwise.

Some of these thoughts gave impulse to the creation of the Committee on Development and to the creation of our own committee. The formation of these committees is interesting; they consist of one member from each Section and of several members at large appointed by the President. With our committee a temporary executive committee was appointed by the President to handle all business previous to the first sessions of the general committee and to prepare a program. A meeting had been planned for the last days in October in connection with the Indianapolis Mid-Western Sections Meeting, but this had to be postponed on account of the influenza epidemic. So, Monday and Tuesday of this week we had our first meetings, and no doubt you wish to know what we have accomplished. We had with us representatives from almost all the Sections. Our work, of course, has reached no final stage, but we have passed two resolutions, which I am instructed to present to you. The first one reads as follows:

Broader Scope for Society Recommended

Whereas, The engineer has been in the past too closely concerned with the purely technical side of his work, and as a consequence has not, in general, occupied a position of influence in local and national affairs, and

Whereas, By education and training he is preëminently fitted to deal with many matters of great importance in public and private life, and

Whereas, The services of the engineer in such matters will be welcome if he will qualify in this broader sense, be it therefore

Resolved, That to this end the scope of The American Society of Mechanical Engineers should be broadened to give full recognition and encouragement to the individual engineer to accept the opportunities offered in today's widening activities, such as:

1 In his relations to his own work
2 In his relations to the community
3 In his relations to other engineers.

These resolutions express the thought that opportunities await the engineer in public life, and that he will be welcome to render service to the community as soon as he will fully qualify for it. And these resolutions recommend that The American Society of Mechanical Engineers extend the scope of its activities, so as to aid its members in their preparation for the broader activities now presenting themselves. It is a resolution of a most fundamental character; it suggests that if the engineer today does not hold the position in public life which he believes he is entitled to, the fault is largely with himself.

There is this continual complaint that engineers are not receiving what is due them. All sorts of panaceas are proposed to remedy this situation. One thinks licensing of engineers is what we need, another one believes in advertising our achievements; most are looking for the trouble outside the family and not within. The resolution expresses a different attitude. It is necessary to realize the shortcomings of many, and perhaps of most, of us. They are largely the result of the character of engineering work. Most engineers are little in contact with the public in their daily occupation. Their work most frequently requires great concentration, and quite often must be kept secret. Engineers, therefore, do not come much in contact with the people the way the lawyers do, for instance, and their relations, except with other engineers, are mostly with superior or subordinate. Furthermore, the engineer's whole training is largely mathematical and educates him to a step-by-step reasoning; it rather curbs imagination—so necessary for big things.

Publication Policy Endorsed

The other resolution the Committee wishes to present to you today deals with the literature of our Society as a means of broadening the scope of our activities. It also states that the Committee on Aims and Organization is vitally interested in this literature as a means of establishing closer contact with the membership at large and of securing a fuller expression of its sentiment. The resolution reads as follows:

Whereas, One immediate and powerful means to broaden the scope of The American Society of Mechanical Engineers would be the strengthening of its literature, and

Whereas, It is vitally necessary to establish a closer point of contact between the individual member and the Committee on Aims and Organization, in order that the committee may better express the sentiment of the membership at large, therefore be it

Resolved, That the Committee on Aims and Organization supports the recommendation of the Publication Committee regarding the increase in the frequency of issue of The Journal in its contemplated improved form as a matter upon which immediate action is necessary.

The foregoing resolutions, if followed, will involve certain changes in the organization of The American Society of Mechanical Engineers which will require more careful consideration, and the Committee wishes me to say that on this subject, as on many other subjects, it is not ready to make any suggestions at this time.

On the preliminary program, discussed at the Committee meeting and here reproduced, there are many subjects of interest to us. Additional ones should, without doubt, be added. These subjects are intended just as a hook to hang a coat on. They are to serve as guides in our discussions, and they have helped us in the formation of three large sub-committees for the consideration of the main subjects under captions A, B and C. These committees will take up these broad topics, will discuss them with such members of our Society as have already devoted a great deal of thought to some of the individual subjects like standardization, research and others, and will report to the general committee at its next meeting. They will outline their suggestions as to a broadening of various fields and as to entirely new activities. The Committee members will discuss most topics with their respective Sections, and in this manner help to crystallize the views of most of our membership. The Committee hopes that suggestions will be sent freely for its guidance.

You may feel that the Committee has not produced much as a result of two days' sessions. But consider this. The Committee must approach all subjects and all views presented with an open mind. It surely must not rush into the formulation of resolutions except on some most fundamental points, for the discussion should remain in a state of flux. Our views on some of the great subjects here before us may be different a few months hence from what they are today.

May I, then, be permitted to express a few thoughts that have passed through the minds of some of us during the last few days or in connection with the preparation of the preliminary program. They are thoughts and ideas that have not taken definite form as yet, but they will occupy us much in the months to come. In doing this I am speaking not for the Committee but on my own responsibility.

Let me say that neither myself nor any one with whom I have talked so far has advanced a finished program for our Society's activity or the profession's organization. But the general belief is that a free and nation-wide discussion will lead to a crystallization of ideas and to a plan of liberal coöperation between all engineering organizations.

Type of Organization Wanted

Our Committee is called the Committee on Aims and Organization, and the preliminary program placed before our Committee, as you will note from the copies here distributed, follows this name. What, then, should be our aims? what organization will be necessary to carry them out? Let us consider for a moment along broad lines what our aims should be. As individual engineers we wish assistance in our work; we wish to help each other and our profession in many matters affecting mainly our group, rather than the community at large. And in these activities we are joining hands with other men of similar education and similar training as ourselves. But there are other aims, may I call them public aims; the desire to render service to the community in matters in which our engineering training makes us essentially fit to have an opinion and a worth-while judgment. In any such activity we must join a larger group than in our professional activities if we expect success. Just how large the group should be I am not prepared to say. But just remember this: If the group looking for public influence consists of fifty thousand highly educated men, one hundred thousand or two hundred thousand will remain outside, all familiar with the same problems and vitally interested in the same decisions which affect the fifty thousand engineers. These hundred thousand or two hundred thousand men will have to be convinced inside or outside our group. But will they be convinced by our arguments more readily when excluded from our councils? The world has talked democracy for four long years. Most everybody has done some thinking as to what this ideal really is for which so many have died. Give democracy a trial. If those who have had the benefits of education are not able to lead the economic group of which they are a part, if they cannot convince the men who have a certain understanding for the special problems to be considered, how then are they to convince the whole community? And if we do prevail in one group, we shall have a powerful array of men on our side to spread the gospel among all levels of society.

Organization of the engineering profession, then, must deal with two separate groups of aims and with two separate groups of partners with whom we wish to join. When looking at the problem in this manner, it becomes at once apparent that possibly two entirely different types of organization may be wanted, one for professional work and one for public activities. Let us follow up this thought and let us see how far existing organizations may be used. When we aim at technical discussions, when we wish to further research, standardization, the art of management, and so forth, when we wish to bring the engineers together, according to their main interests, we can, in principle, hardly much improve upon the grouping we now find in our national societies. Of course, we always see occasion for improvement here or there in the methods we are following. We need more local sections, for example, for the reason that not all members can come to headquarters to participate in technical discussions. Sections should be encouraged to coöperate with other local sections and to affiliate with local engineering societies. This has so successfully been done in several localities that it should be further encouraged. But, above all, more coöperation is needed among the national societies themselves. Just in what manner this should be done is an open question; whether by bringing all national societies together into one society or simply by closer and closer contact between them and more joint committee work, it really matters little. But more coöperation in some form is the gospel we should preach.

A Way to Get Representation

As stated before, I am far from having a ready-made program to offer, and, of course, the Committee has not as yet reached any final conclusion. But may I suggest that successful activity in public matters on the part of engineers has so far been practically limited to local all-inclusive engineering societies. I know that I am not expressing the views of all the members of the Committee when I say that the local all-inclusive engineering society is the best agent through which the engineer can render public service. But it seems so to me; first, because there are many more local problems that interest him as engineer than state or national problems; and, furthermore, because the local all-inclusive engineering unit lends itself most readily as the basis of state and national organizations for public engineering service, organizations which must adapt themselves to the existing organization of our country so that mobilization will easily be possible in cities, states and nation. There seems to be no reason why a number of such local units, located in one state, cannot appoint delegates to a state body consisting of such delegates, and thus secure a fair representation to the engineering group of the state in question. We have seen a development in this direction in Ohio. And why should we not go further and have representatives of all such local bodies joined as a national body representative of the country's engineering group. In other words, the local unit would be the basis of our whole structure for public service, as opposed to our organizations for professional aims, formed on a national basis and along lines of specialization. The local unit would be all-inclusive and would act direct in local matters while acting through delegates and representative bodies in state and national affairs. And the national societies should be represented on the national body.

No matter, however, what means may be adopted as best suited, what should be emphasized is this: The issue is not individual activity but group activity. The issue is not, as frequently expressed, that, of course, the engineer must be a good citizen like everybody else; it is not a question of voting the Republican or Democratic ticket. The division must be a different one. It is a question of making available to the community the combined training and combined experience of the group of engineers, just as I hope other groups of men will do in the days to come.

Our Duty to Understand Labor

And in the consideration of the problems that are before us, may I suggest this thought, a thought discussed quite frequently by some of us. Among all the educated classes, the engineers are the one group in closest touch with labor. It is the part of wisdom and our duty to Society to try to understand the strivings of the working classes for our own benefit and to interpret them to the rest of the community. If the British Labor Party has been able to frame a reconstruction program and to produce a document commanding the admiration of most thinking men, surely it behooves us, the engineers, the men of whom, on account of training and experience, industrial leadership might reasonably be expected, to discuss the mighty problems now before us. And just to show how old this thought is in our Society, let me read a paragraph from Dr. Thurston's Presidential Address in 1882, the third year in the existence of our Society:

> In singular and discreditable contrast with all the gain in recent and current practice in engineering stands one feature of our work which has more importance to us and to the world, and which has a more direct and controlling influence upon the material prosperity and the happiness of the nation than any modern invention or than any discovery in science. I refer to the relations of the employers to the working classes, and to the mutual interests of labor and capital. It is from us, if from any body of men, that the world should expect a complete and satisfactory practical solution of the so-called "labor problem." More is expected of us than even of our legislators. And how little has been accomplished?

We speak so frequently of reconstruction, but as on the battlefields of France this cannot mean the restoration of all the old and often unwholesome dwellings that have been destroyed, so the reconstruction that we have in mind should not mean a re-establishment of institutions superannuated long ago but only broken down in the days of stress that we have passed. Many of the old conditions we do not want again; the *status quo ante* is not desired; and even if desired could not be revived. But what we wish is a renaissance rather of our institutions, with higher ideals and a clearer purpose than we have had before.

BUSINESS MEETING

Proposed Constitutional Amendment to Provide for Representative Nominating Committee—Addresses by Presidents of Civil and Electrical Engineers—Presentation of Report by Aims and Organization Committee

The annual business meeting of the Society was held in the Auditorium of the Engineering Societies Building on Wednesday, December 4, at 10 a.m. After calling the meeting to order, President Charles T. Main announced that the Committee on Constitution and By-Laws was ready with a report on the proposed amendment to the Constitution and that it would be presented by Past-President Jesse M. Smith, chairman of the Committee.

Mr. Smith stated that the proposed amendment was designed to take from the hands of the President the appointment of a Nominating Committee for officers of the Society and put that authority into the voting membership. The committee, who had considered the amendment at length, had couched it in broad language so as to permit of one or more nominating committees being appointed, and had left the matter of details as to formation of committees, their number and procedure to be handled by by-laws.

On motion of Prof. A. M. Greene, Jr., seconded by L. C. Marburg, it was unanimously voted to submit the proposed amendment (published in The Journal, December 1918, p. 1066) to letter ballot.

At the request of President Main, the Secretary briefly commented on some of the outstanding features of the reports of the various Standing Committees of Administration, and stated that it was the urgent desire of these committees to obtain an expression of opinion on the part of the membership regarding the work of the Society. The Finance Committee, he said, was dealing with a budget larger than that of any other professional society in the world, save two, amounting to $236,000 for the coming year, which, it might be stated, was well within the income of the Society. The Meetings and Program Committee, it would be seen in their report, was extending the scope of the work of the Society so that it was really becoming a society of the industries. In close connection with their work was the recent action of the Publication Committee in recommending the purchase of the Engineering Index, ownership of which had now been acquired from its former publishers. It was proposed to further extend the usefulness of the Index by making avail of the unequaled facilities afforded by the Library. With the growth of the Society, whose membership had almost reached the 10,000 mark, and the realization of projected plans regarding its publications, its revenues would not only support all of the present activities but would make it possible to appropriate substantial sums for research work. The vote that had been taken on the proposed amendment he regarded as the most momentous in the history of the Society.

A. W. Robinson emphasized the importance of the Society's broadening its activities by taking up economic questions, such as the conservation of natural resources, coal consumption, the gasoline problem, ocean transportation and the like, and not leaning too much to mechanical details.

Addresses by Prof. A. N. Talbot and Prof. Comfort A. Adams

The latter half of the meeting was devoted to a consideration of the work of the Society's new Committee on Aims and Organization. Prior to the presentation of the preliminary report of the Committee, however, President Main called upon Prof. A. N. Talbot, President of the American Society of Civil Engineers, to address the meeting on this subject. At the conclusion of his remarks, Vice-President Charles T. Plunkett was asked to occupy the chair, whereupon L. C. Marburg, chairman of the Committee on Aims and Organization, presented its report. Abstracts of the addresses of Professor Talbot and Mr. Marburg follow this report.

Chairman Plunkett then introduced Prof. Comfort A. Adams, President of the American Institute of Electrical Engineers, who spoke briefly on the public service the engineer should render to society.

At this particular time, said Professor Adams, with the whole civilized world in a state of ferment, it certainly behooved us to take account of stock, not only to investigate our work in the technical field, not only to see whether we were serving our profession as professionals, as individuals, as a rank and file, but also, and equally important, to see whether or not we were serving society by playing our part in the great movements that were going on about us.

The American Institute of Electrical Engineers, he thought, was, if not the first, one of the first of the societies to take cognizance of the interests of its outlying members by the establishment of sections throughout the country, and this establishment of sections and branches—branches being established in the educational institutions—had proved very helpful. There were, however, many problems common to all the societies which had to do with the meeting of the demands and the interests of the rank and file of the membership, and one of the most important features of this broad task of review, development and progress of an organization should be the consideration of the interests of its members at large.

But we must go even further than that as individual societies—we must take cognizance of our relations to each other as societies. We were coming more and more to realize that there was no line of demarcation between civil, mining, mechanical and electrical engineering, and no sharp dividing line between engineering and industry, industrial management, administration, politics, economics and many other things. We were so intimately associated with these outlying fields, these broader questions of industrial economics of labor and capital, that it was impossible for us if we were to take our proper place in society, to sit down and allow lawyers and editors to handle these great questions alone, and we to stand apart and aloof. We must get into politics and take a hand in the legislation of the nation.

It had often been said that the engineer's training was such as to give him a position of special advantage, because he was dealing with the hard and fast laws of nature, which did not yield to his individual interest—he was forced to think straight. That was all very true, in so far as he was strictly a technical engineer, but much of our work got outside of that.

Moreover, the engineer was many times at a disadvantage, because he was in such close touch with the financial end of things that it sometimes outweighed the other side of his training. We were not less human than members of other professions, in all probability, in being swayed by our own immediate material interests. But we had, nevertheless, this background of law and science on which we should be building, not only an engineering structure, but we should be able to apply these same principles and these

same habits of thought to the solution of many of our economic problems.

The labor question was one of the most difficult problems before the nation in this reconstruction period. We could meet it in a progressive way, trying to face it fairly and squarely, to set aside tradition and past methods and clearing away divisions of personal interest, and realizing that the real interests of labor cannot be separate or distinct from the real interests of capital or the engineer. Or we could employ the method of suppression; but that, like the suppression of the expanding power of explosive force, was apt to result in an explosion. This was no light matter—it was not a mere conjecture—explosions of this nature had occurred in other nations, and it was not an altogether foregone conclusion that they might not occur here.

Suggestions for the Organization of Engineers, by Past-President Jesse M. Smith

Following the remarks by Dr. Talbot and Professor Adams, Past-President Jesse M. Smith said: "I have listened with very great pleasure to what the President of the American Society of Civil Engineers has said and to what the President of the American Institute of Electrical Engineers has said, and it only goes to show how very closely we are getting together as a body of engineers, without regard to specialty. In this connection I am tempted to read from a letter which I recently wrote on the question of the comprehensive organization of the Engineering Profession in America and the relations of such an organization to the present United Engineering Society.

The Charter and By-Laws of the United Engineering Society are very broad in their scope and cover many functions which have not as yet been utilized.

The U. E. S. at first only utilized one of its functions: namely that of a holding society for the American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers and American Institute of Electrical Engineers, which are the "Founder Societies," by which the title to the real property owned jointly by the "Founders" might be held by one society. This function I have always considered a minor function but a very valuable one, particularly in the early days when the first steps were taken to solidify the profession.

Other functions have from time to time been utilized but none of them to their full extent as yet. I refer to the Library Board, the Engineering Foundation and the Engineering Council. The work of each of these boards has been well started and will be perfected and extended. The proper financing of these different Boards seems to me to be the principal difficulty and should be undertaken by *one society*.

Now comes what seems to me to be the *principal function* of the U. E. S.: the *purely professional function*.

In order that the profession may be truly solidified, I believe that there should be *one* American Engineering Society and that the U. E. S. and its four Founder Societies should be merged into *that one*, not only for business purposes but also for social purposes and for the general good of the profession, but principally for *purely professional purposes*.

Let me briefly outline a plan which has been revolving in the back of my head for several years.

1. Let the members of the four Founder Societies take membership in the American Engineering Society in such grades as they are qualified to occupy according to the present qualifications for membership in the Founder Societies. These qualifications are now substantially the same in each of the four Founder Societies.

2. Let all other engineers, who are members of other societies or are not members of *any* society, take membership in the American Engineering Society according to their ability to meet the qualifications established by this society.

There would thus be created a National Society of enormous membership, of 100,000 or possibly 200,000 members.

Such a society would be unwieldy for the transaction of its affairs, either professional or business, were such affairs not committed to boards or committees. Many engineers regret the passing of the smaller societies where the members came into close personal touch and the papers were freely and intimately discussed. This was true of each of the Founder Societies in their earlier days—but those days have now passed.

To meet these objections, which are real, it is proposed to form the large membership of the American Engineering Society into branches—or groups according to *Specialties in Engineering*.

Each of the four Founder Societies contains engineers of quite different specialties. For example, the Civils contain railroad engineers and hydraulic engineers; the Miners contain metallurgical engineers in iron and mining engineers of precious metals; the Mechanicals contain steam engineers and machine-tool engineers and the Electricals contain telephone engineers and power-transmission engineers, and there are still other specialties of importance in each society. Many of the specialties have no close relation to each other in a technical sense but they all are a part of the engineering profession.

Suppose, for example, there be ten or fifteen such branches or groups, which number could be increased as the demand required.

Each branch should consider *only purely professional subjects* in its own specialty and its affairs should be in charge of a committee of its *own members* elected by the *members* of the branch, and should be presided over by a vice-president, also *elected by the members of the branch*, and who should also be a member of the governing body of the society.

The governing body or Board of Directors of the society should consist of:

The President to be elected by the entire voting membership of the society.

One Vice-President to represent, and be elected by, the voting membership of each branch.

One Director to represent, and be elected by, the voting membership of each branch.

A Technical Secretary of each branch.

A General Secretary of the society.

A Treasurer of the society.

The Board of Directors should control the general affairs of the society and direct the policy of the society as well as the general policy of the branches, leaving to each branch the detail of the conduct of its own meetings.

All publications should be undertaken by the society. The proceedings of each branch should be published as a separate volume. One volume should be given to each member of the society free of cost, but he should have the right to subscribe for as many other volumes as he would care to pay for at cost price. All volumes should be available for sale to the public at more than cost price for the benefit of the society.

Membership fees in the American Engineering Society should be as low as possible in the junior grade and increase with the higher grades so that there would be ample funds from membership fees to meet the requirements of the society in all its activities.

So much in a broad way for the professional side of the question.

Now for the social side: The getting together of engineers in elbow touch for conference and social intercourse is quite as important as the professional contact.

The social and professional contact should not, however, interfere with each other and should be organized in a sense independently of each other. Members of the society should all be eligible to membership in the social organizations but should only become members of those social organizations upon the payment of a separate fee for the support of those organizations.

The American Engineering Society should encourage the formation of a series of engineering clubs in different cities which would be the centers of engineering activities in those cities and which would naturally be the centers of professional sections of the American Engineering Society in those cities.

When the Founder Societies and other engineering societies are merged into the American Engineering Society the local sections of these various societies would also naturally be merged and have their centers in local engineering clubs.

Local engineering societies might also be merged into such local sections and clubs.

A member of an engineering club in any city should be given the privileges of the engineering clubs in other cities.

Professional engineers will only become a real power in our country's affairs when they are consolidated for coöperation in professional work and become *a single unit* in all that relates to the profession at large.

In the short time remaining for discussion the addresses of the morning were briefly discussed by Dr. John A. Brashear, J. Clinton Parker, L. W. Wallace, H. H. Suplee and Spencer Miller. Dr. Brashear cited instances from his experience with Presidents Cleveland, Roosevelt and Taft, showing the interest they had taken in scientific matters submitted to them and their willingness to be of assistance. Mr. Wallace was of the opinion that engineers should make their influence so potent in economic, industrial, political and engineering matters that the public would be forced to realize that they are a body of highly trained professional men deserving of high recognition and appreciation. Mr. Miller spoke of the recognition the engineer is now receiving in Washington. He counseled brevity in any statement of aims and thought it would be fortunate if such an expression could be brought down, say, to fourteen points. The meeting then adjourned.

ENGINEERING SOCIETIES' COMMITTEES ON AIMS AND ORGANIZATION

By ARTHUR N. TALBOT,[1] URBANA, ILL.

The work given to the committees which have been formed by at least three of the Founder Societies has its purpose well expressed by the name given to the committee of The American Society of Mechanical Engineers—the Committee on Aims and Organization. The resolutions of the Board of Direction of the American Society of Civil Engineers creating the Committee on Development of that society instructs the Committee to report on the purpose, field of work, scope of activity and usefulness, organization, and methods of work of the society. It is apparent that the committees have much in common and that there should be full and free coöperation. What should be the aims and purposes of such societies, how they may best be organized for present-day conditions, and what they may be expected to accomplish are then within the scope of the work of these committees.

These are times of development. The great world war and all the attending phenomena have brought about new conditions. Men are thinking outside the lines which formerly limited their thoughts and methods. The existing state of flux in sociological and economic conditions may deeply affect the opportunities and responsibilities of the engineer. Great changes and great development may be expected to follow. It is apparent to many observers that a larger sphere of activity and usefulness will be opening to the profession of engineering, if only the engineer is ready to undertake his part now and later. And, besides, the engineers' work has developed so rapidly and so diversely in the past forty years that we hardly know where we are. Engineering societies have grown at a very rapid rate; local and specialized engineering societies have sprung up everywhere. The conditions in the more remote parts of the country may differ materially from those in and around New York. In all there are some 35,000 members of the four national engineering societies. How many there are in the hundreds of local and specialized engineering societies, is not known. It is considered by some that the number of men who may justly claim the right to be classed as engineers runs up to more than 100,000.

In view of all this is it not well to seek to make a survey of the aims and purposes of the engineering societies, to ask whether they are occupying all the fields of usefulness open to such societies and whether they are accomplishing all that may reasonably be expected of such organizations?

Even if the survey made by the committees should result only in broadening and intensifying and emphasizing the activities, functions and methods of work already in existence, the effort will be worth while. More likely, the study of the problems will show new opportunities and responsibilities devolving upon the societies, and especially that, whether inside or outside the field of the national engineering societies, there are matters of public and semi-public nature which should be considered by the engineering profession more fully than has been the case in the past.

In taking up this inquiry no one should feel that the consideration of aims and organization is in any way a reflection on the conduct of our societies in the past. All will agree that their record is most excellent. The accomplishments of the societies, technical and extra-technical, redound to the credit of the societies and their membership. These societies have helped to create the engineering profession. In ways that are not usually recognized the engineering society has been a benefit to the engineering profession and to the public. It has given esprit de corps to the profession. It has made its members feel self-respecting—more, it has shown many the high standing of the profession and the responsibility attached to membership in it. It has raised the standards and the standing of the engineering profession, and has assisted in establishing this standing in the eyes of the public. In such ways as this it has more than justified its existence. But may not the engineering society do even more than it has in giving standing to the engineering profession?

The engineering society has been very helpful in technical matters. In fact, in the eyes of many, the presentation and discussion of papers on technical engineering subjects should be almost the sole function of the engineering society. This is a worthy function. Engineering is and must continue to be a technical art, a technical business. Is it not likely, with the great development of the science and art of engineering, that the engineering society has not yet realized the possibilities of its usefulness in developing, recording and disseminating the technical side of engineering, the scientific substructure, the overlying elements of practice, the variform connections with business life? Especially may it not be more fruitful in contributing to engineering knowledge and in creating or developing new engineering policies, and in developing engineering practice and engineering improvments?

If one were to recount the accomplishments of the engineer in civic affairs, in governmental activity, in influence upon public policy, in the solution of industrial problems, the record would be surprising and greatly to the credit of the engineer. The accomplishments of the engineering societies along these lines are likewise very creditable. But as new conditions teach new duties, it is worth while inquiring whether the engineer and the engineering society have not now opportunities and responsibilities in the direction of public duty far beyond that which has usually been considered a sufficiency. If a need is found, means must be found for expansion, if such expansion is practicable. The problem is a complicated one. The engagements of most engineers are not like those of the lawyer. There is a great diversity of condition of service and environment, even in the same lines of engineering. It is also evident that matters affecting general public policy, to have the best effect and the greatest influence, should be discussed by all branches of engineering in every part of the country; and matters of regional, state or local interest may be handled only by those in the localities interested.

It is becoming more and more apparent that engineering is a single profession; the various branches merge and ramify into each other in numerous ways. Many engineers think that there should be one large inclusive engineering society to take the place of the several national societies—but evidently that is not a present probability. Much has been done in recent years in the way of coöperation and united effort; the United Engineering Society and the Engineering Council have unified action in commendable ways, there is a great field for their further endeavor. In any discussion of the subject it must be borne in mind that the membership of the national societies is scattered over the country; that there are numerous centers of engineering and that these are yearly becoming more important; that local engineering societies in these centers are essential elements in the life of the engineering profession; that these local societies furnish the means by which the young and growing man meets and knows other engineers and gains opportunity for development; and that the national societies may be greatly strengthened and their influence extended by closer affiliations with these local societies; and that any thorough consideration of the subject of aims and organization should endeavor to find ways and means by which the sections of the national societies may best effect close coöperation with the local societies and extend the opportunities of members and the influence of the engineering profession. The problems of the coördination and unification of the engineering profession are numerous and complicated, but nevertheless no one will doubt that every effort should be made to strengthen organization and to attempt to make the engineer a greater force in the world.

It is apparent that the subject assigned to the committees will require diligent and earnest study and consideration, and that their reports will need careful deliberation by the societies. What are the best lines for expansion and improvement and what may be accomplished for the good of the profession and the public are matters which may well tax the powers of the committees and the membership; what is practicable and what is visionary; what may be done by the engineering society and what may best be relegated to individuals or to auxiliary or separate organizations or given up entirely, must all be threshed out in detail.

[1] President American Society of Civil Engineers; Professor of Municipal and Sanitary Engineering, University of Illinois. Mem.Am.Soc.M.E.

Abstract of address delivered December 4, 1918, at the annual meeting of The American Society of Mechanical Engineers.

THE ACHIEVEMENTS OF NAVAL ENGINEERING IN THE WAR

By LIEUT.-COM. WILLIAM L. CATHCART,[1] U. S. N. R. F.

DURING these more than four years of war we have heard much in criticism of the Silent Fleets—of the mute guns of that vast Allied Armada waiting tensely, like a crouching lion, for the German High Seas Fleet, which—save for its half-hearted dash at Jutland—never came.

And yet, notwithstanding these criticisms, the ex-Kaiser, his craven commanders on land and sea, and now all Germany know that to those Silent Fleets is due primarily the shattering of their dream of world dominion—a dream whose realization meant to us and to our Allies but world despair.

This assertion of the paramount value of sea power involves no detraction from the honor fitly due those magnificent Allied armies, the white crosses of whose dead crowd all Europe. And it minimizes in no way the achievement of the superb troops of the American Expeditionary Force, who—in but half a year's hard fighting against the flower of Germany's armies—have won undying glory for our flag.

But, predominating sea power was the foundation on which all of these victories on the land were based. From the beginning, the British Fleet attained the ultimate object of all sea warfare, in making impotent the enemy's naval strength in surface warships—the only kind that count in the end—and that impotence has had a vital effect on the conduct and success of the war.

The reason is clear. Every one knows now that an army on the land or a fleet on the sea becomes helpless if its lines of communication with its base are cut. In this conflict, the Western Front was the decisive theater of war. And for the Allied armies on that front the ultimate bases of supply and reinforcement lay beyond the sea—in Great Britain, her colonies and dominions; in India and Algiers; and—most important of all—in distant America.

So, the absolutely vital lines of communication of those armies stretched like a vast network across the Seven Seas. And, if Germany's High Seas Fleet had been free to wreak its ruthless will, those lines would have been quickly cut, England would have been isolated, America powerless to aid, and long before we could have entered it—the war would have ended in bitter tragedy for all mankind that is worth while.

While the defeat of the Central Powers is thus due primarily to the early strength and continuous growth of the British Fleet, our own Navy has had no inconsiderable part in the decisive work of the war's last year. It has convoyed across 3000 miles of sea more than a third of that American Army of two million men which gave preponderating military strength in France—an achievement which, for rapidity of execution and the distance covered, is without parallel in the history of navies. During the last three months of the war, for every minute of the day and night, seven American soldiers, their equipment, and the maintenance for them, arrived in France.

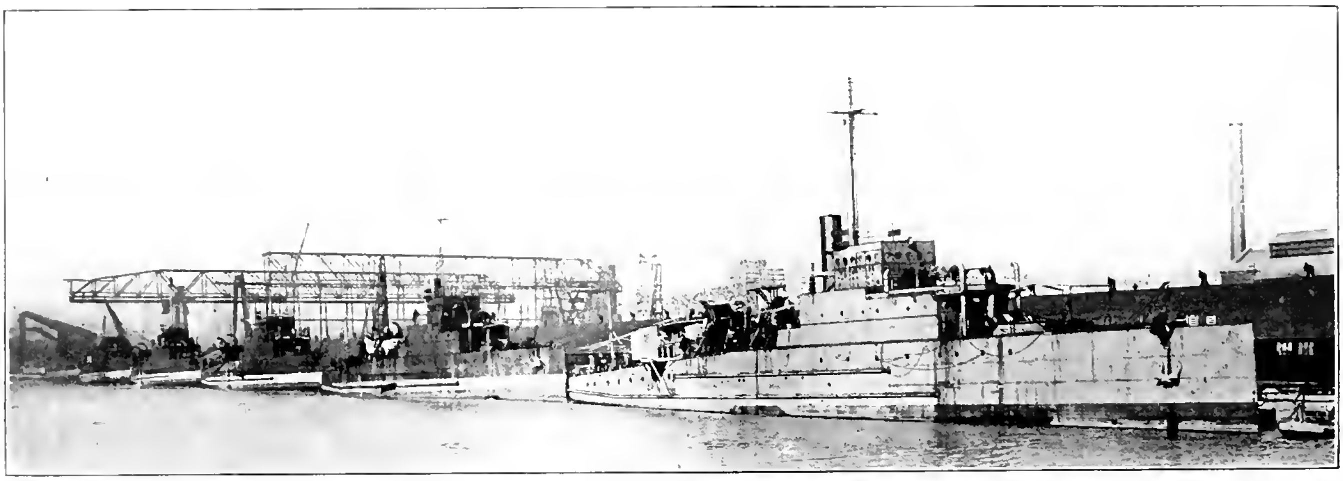


Fig. 1 The "Eagles"—Ford Boats

Our Navy in This War

From the very day of America's entry into the war our Navy grew by leaps and bounds until it became 600,000 men strong and operated about 2000 armed vessels and transports. On September 1 we had in European waters a total of about 275 ships carrying about 57,000 officers and men under command of Vice-Admiral Sims. These vessels comprised: First, a large division of dreadnaughts in the North Sea; second, cruisers serving with the British in the White Sea and the North Sea, with the British and French in the Atlantic, and with the French, Italian, and Japanese in the Mediterranean; third, about a hundred destroyers operating from several European bases; fourth, a swarm of submarine chasers dashing through British, French and Italian coastal waters; fifth, a flotilla of submarines engaged in hunting enemy boats of their own kind; sixth, a number of small patrol vessels—coast guard ships, yachts, seagoing tugs, and the like; and, finally, some naval auxiliaries, such as mine layers and repair ships.

But, the story of the Navy in this war is very far from ending with the record of its ships in European waters. For, we have maintained also a huge Atlantic Fleet whose vessels have not only guarded our coasts and the near-by ocean lanes, but have formed a great training school from which have come the picked men for European service, the gunners for many hundreds of merchant vessels carrying armed guards, and the crews for Army transports and for the Naval Overseas Transportation Service—that is, the vessels built by the Emergency Fleet Corporation.

When we remember that the maritime area of this country forms so small a part of the whole, the wonder is that, in so brief a period, 600,000 men—coming largely from interior states—could be trained for efficient service afloat in our home and foreign fleets. Sir Eric Geddes justly terms the achievement of the Bureau of Navigation in this work as "an amazing feat."

But, what is thus true of one Bureau in this war, is equally true of all in the Navy Department—the great shore establishment which stands behind the Navy afloat and without whose full efficiency, effective service by our Fleet would be impossible.

So, what follows of the record made by the Bureau of Steam Engineering should be regarded as but a sample of what all these Bureaus have done. From the beginning of the war, the entire Navy Department has been working, in a clean-cut American way, at maximum efficiency under forced draft.

[1] Bureau of Steam Engineering, Navy Department. Mem.Am.Soc.M.E.

Address (abridged) delivered at the Annual Meeting of The American Society of Mechanical Engineers, December 4, 1918.

I shall limit my lecture to the work of the Bureau of Steam Engineering, and shall be able to handle even that work only in a very general way, since the Bureau's field—which is dynamical engineering largely—covers all steam and internal-combustion engines for the Navy; the bulk of its electrical machinery and apparatus for surface ships, submarines, and aircraft; the machinery and apparatus of aircraft; the generation and supply of gas for observation balloons and dirigibles; and finally the design and supply of the entire wireless equipment of all shore stations for radio telegraphy in the United States, in our island possessions and on every vessel, merchant or naval, flying the American flag.

The Stupendous Task of the Bureau of Steam Engineering During the War

When the war began, we had a Navy of about 350 ships—commissioned, in reserve, or building. But, the fleet grew with amazing rapidity, and, at the close of the fiscal year on June 30 last, the Navy had in service, or soon to be commissioned, a total of 1959 vessels. This total comprised 570 ships of the regular Navy; 93 drawn from other Government services; 937 converted merchant ships, used as troop transports, naval auxiliaries, and in patrol; and, finally, 359 vessels built by the Emergency Fleet Corporation for the Naval Overseas Transportation Service.

The aggregate horsepower of these vessels is about 6,500,000—which is thirteen times that of our fleet during the Spanish-American War. And, further, it is more than ten times the power developed on both sides of Niagara Falls, and is also equal to about one-sixth of the primary fuel and water power now employed in land service in the United States, not including the locomotives.

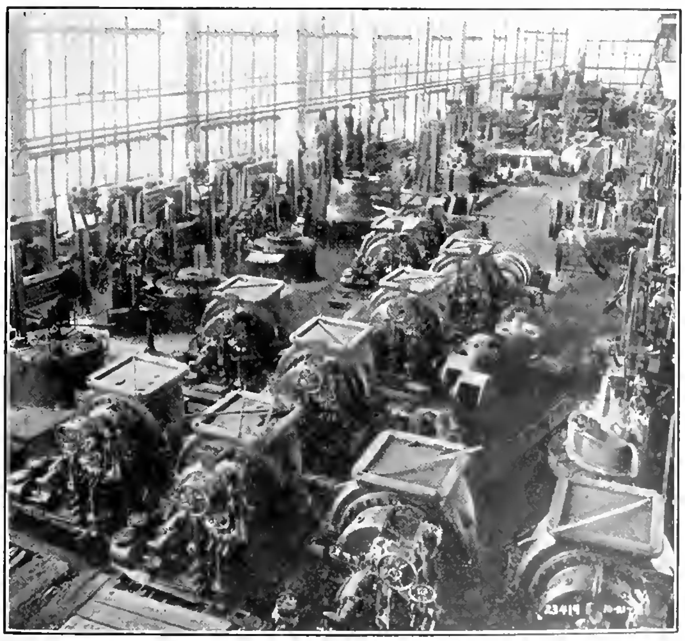

FIG. 2 MACHINERY FOR THE "EAGLES"

But the maintenance of machinery of this huge power was not all, for at the close of the fiscal year there were under construction 376 combatant and auxiliary vessels and 52 tugs for the Navy. Included in this number is a huge force of destroyers. When these vessels are completed, the present horsepower of the Navy will be increased by 70 per cent, and become 11,000,000.

Organization of the Bureau of Steam Engineering

For clearness in discussing the work of the Bureau of Steam Engineering, let me give a brief outline of its organization and principal activities.

The Engineer-in-Chief determines all questions of Bureau policy, authorizes all expenditures, and decides all important—and many minor—questions of detail.

The Assistant to the Bureau, Captain Oscar W. Koester, handles routine business in technical and administrative matters; investigates all work and expenditures in connection with the organization, building, equipment, and maintenance of the shops of the Machinery Division at Navy Yards and Repair Bases; and, when necessary, inspects and reports on the condition of the Bureau's work at private plants.

The staff of the Bureau is separated into ten divisions—one clerical, headed by the Chief Clerk; and the remainder, technical. The duties and titles of the nine latter divisions are: Design,

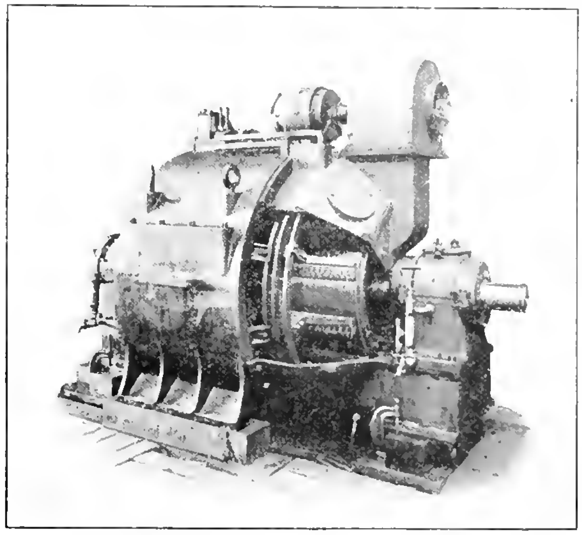

FIG. 3 MOTOR FOR SUBMARINES

Electrical, Repairs, Radio Telegraphy, Inspection, Supply, Fuel and Personnel, Aeronautics, and Logs and Records.

Each of these divisions is in charge of an officer who is an expert of high rank in his especial field. The muster roll of the Bureau's divisional heads is in this respect a roll of honor. While the work of the Bureau is thus divided, Admiral Griffin keeps in close touch with it all. His guiding hand is felt, in greater or less degree, in every detail.

Division of Design. The Division of Design is in charge of Rear-Admiral Charles W. Dyson, an officer who has long been widely known for his success in the design of naval machinery, and especially of propellers—that marine mystery of many weary years.

The duties of this Division cover a broad field. As to new vessels, for example, it recommends the type of machinery to be adopted; estimates the power required for propulsion; makes the general design of the machinery selected by the Engineer-in-Chief; draws the contract-plans and specifications; investigates the bids and alternative plans submitted by contractors, and makes recommendations; criticises the detailed plans forwarded by contractors; prepares directions for the trial of the machinery; and finally makes recommendations as to payments on the contracts.

During the last two years of the war, this comprehensive work was done for vessels of all classes—built, building, or contracted for—aggregating 9,501,440 hp., as follows:

Destroyers	6,578,000	EFC oil tankers	31,800
Battle cruisers	1,080,000	Harbor tugs	12,000
Battleships	480,000	Fuel ships	10,400
Scout cruisers	630,000	Motor tugs	2,800
200-ft. patrol boats	280,000	Ammunition ship	10,600
Mine sweepers	75,600	Oil and water barges	2,400
Sea-going tugs	48,606	Gunboat	1,600
Submarines	41,640	110-ft. patrol boats	216,000

In addition to the work on new vessels, the division passes on all alterations to the existing machinery of naval vessels and those of the Naval Overseas Transportation Service. It also specifies the materials and their characteristics for marine engineering construction, and has general supervision of all tests and experiments relating to marine propulsion at the Engineering Experiment Station at Annapolis and the Fuel Oil Testing Plant at the Philadelphia Navy Yard. Similarly, it has general supervision

of the Inspection Force at building yards—a work in which the Bureau has at this time about 60 officers engaged.

Electrical Division. When we entered the war, the Electrical Division was in charge of Commander Guy W. S. Castle, who has been succeeded very recently by Captain C. E. Courtney.

This Division supplies all the electric power, the wiring for all purposes, and roughly about 75 per cent of all electrical machinery and apparatus on naval vessels. Its field is therefore a

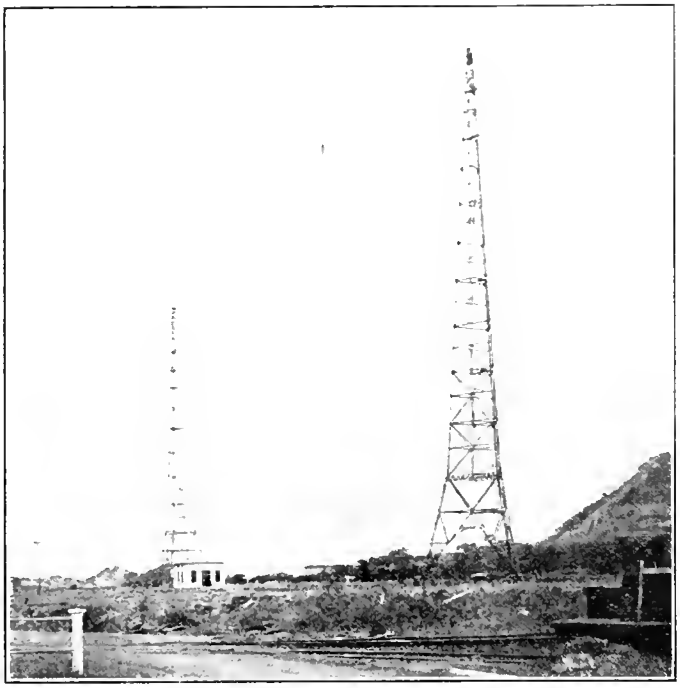

Fig. 4 U. S. Naval Radio Station, Balboa, Canal Zone

Fig. 5 Wireless Telephone Set: Top View

most important one, extending to communication systems for the control of gun fire, the electrical signals for day and night use which are so necessary for the handling of ships in company at sea and in making recognition signals, searchlights for protection against destroyer attack at night, the motors and storage batteries for the propulsion of submarines when submerged, anti-submarine and anti-aircraft devices, all interior communication systems, the multitude of other appliances in which electricity serves on shipboard, and the electrical equipment of the Machinery Division at navy yards. In this work, the Bureau has expended about $20,000,000 during the last fiscal year.

In original work, Commander Castle supervised the development of certain anti-submarine and anti-aircraft devices which are of a confidential nature. These submarine detectors have been made in quantity, not only for our own vessels, but for the British Admiralty and the French Ministry of Marine. For the anti-aircraft investigation, Dr. G. W. Stewart of the University of Iowa made for the Bureau a comprehensive study at Pensacola, Florida, of all the noises made by the engine and wings of an airplane in flight. From his results and in coöperation with the Signal Corps of the Army, a scheme of sound ranging on enemy airplanes was devised, and the necessary instruments were designed and made.

Unquestionably, the most important electrical accomplishments of the Bureau during the war have been the remodeling and improvement of the wiring for gun-fire control systems in all ships from dreadnaughts to gunboats, the installation of communication systems for the service of the guns on transports and ships carrying armed guards, and the provision of recognition signals on all vessels acquired or operated by the Navy.

Supply Division. The Supply Division is in charge of Lieutenant-Commander Charles K. Mallory, U. S. Navy (retired), a member of this Society, who—on the mobilization of the Navy for war service—was assigned to this duty as the relief of an officer on the active list.

Matters relating to engineering materials and supplies—under cognizance of the Bureau of Steam Engineering—for vessels of the Navy and for Navy Yards, are handled through this Division. The specifications for the material are drawn by the technical Division concerned, and all subsequent questions of a technical nature are referred to that Division for decision. Hence, the Supply Division is, in some respects, a sort of center of business activity for the Bureau in its contact with bidders and contractors.

Upon our entry into the war, it soon became apparent that the question of obtaining material and supplies—both for the direct use of the Navy and for those having contracts for new construction—would be of increasing importance and difficulty. Owing to the unsettled conditions as to materials, supply, and labor, it became necessary to abandon the penalty for failure to complete contracts on time, and in many cases contracts had to be changed

Fig. 6 U. S. Navy Twin Engine Dirigible, Showing Bombs in Place, Radio Telephone in Use and Antenna Wire Reeled Up

from a fixed-price basis to one which would insure the receipt by the contractors of a reasonable profit.

Under peace conditions it was unnecessary to give much attention to the matter of the ability of the contractor to deliver as required. This latter consideration, however, became more and more important in war time, and, to take care of the situation, a number of business men of ability—who were willing to devote their time to Government needs—were enrolled as officers in the Naval Reserve Force and assigned to production work in the various Inspection Districts. The work of these production of-

ficers was of inestimable value in obtaining material as required.

The Supply Division has also made a revision of the engineering allowance lists for all regular navy vessels, to insure their being on a proper war footing in this respect. It will be seen that, owing to the variety and volume of its work, this Division has had its hands full since our entry into the war, but its work has been thoroughly done throughout.

Radio Division. Commander S. C. Hooper, U. S. Navy, is in charge of the Division of Radio Telegraphy. The activities of the Bureau of Steam Engineering in this respect cover almost a worldwide field. All matters relating to radio equipment—except the actual operation by the radio personnel—on vessels operated by the Navy, on all vessels of the Army and other branches of the Government including the United States Shipping Board, and on merchant ships requisitioned by that Board, are directed by the Bureau. The number of these istallations now exceeds 4,000.

The Bureau's direction extends similarly to 50 naval radio coastal stations and 75 commercial coastal stations in this country; to others in the West Indies and the Canal Zone, in our island possessions and Alaska and Vladivostok in the Pacific; and finally to one now building for us at Bordeaux in France, which will be the most powerful wireless station in the world.

During the last fiscal year, four of the high-power radio stations on the Atlantic Coast—Sayville, Tuckerton, New Brunswick, and Marion—have been developed into efficient transmitting stations capable of continuous radio communication with Europe. And, further, the Annapolis transmitting station—the most powerful in the United States—was built and commissioned. This station and the four just noted would provide uninterrupted communication with our forces in France, if all submarine cables were cut.

The Bureau has also conducted a large amount of investigation and development of radio transmitting and receiving apparatus for aircraft. It has equipped 90 airplanes in the United States with satisfactory apparatus, has shipped 60 outfits to France and Great Britain, and has contracted for about 3000 more.

Radio telegraphic communication from aircraft in flight to stations on land is now possible at a distance of 200 miles. Similar communication from land stations to flying aircraft is practical up to distances of 50 miles, and communication from aircraft resting on the water to points on shore can be effected at a maximum distance of 40 miles.

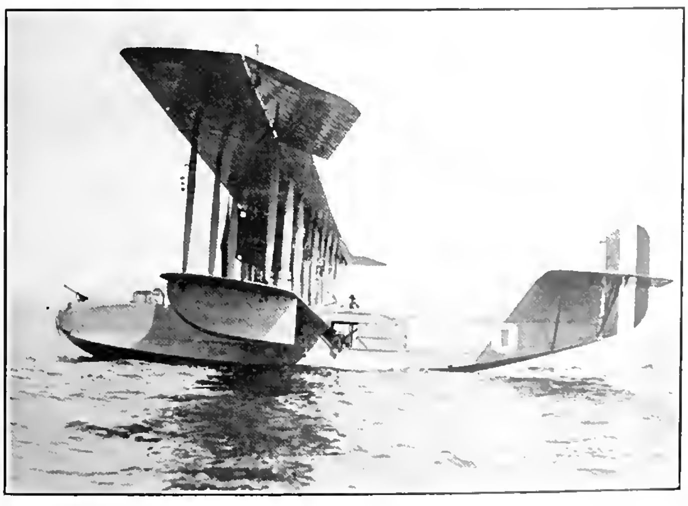

Fig. 7 U. S. Flying Boat H-16 for Patrol Service; Two Liberty Engines; Crew of Four to Five Men

The development of the radio telephone for use on aircraft has progressed to such a stage that it is now possible to communicate by this means from aircraft in flight to stations on land at a maximum distance of 60 miles. The converse of this—telephone communication from land stations to flying aircraft—is practicable at a distance of 15 miles.

Inspection Division. The Inspection Division is in charge of Commander M. A. Anderson, U. S. Navy (Retired). During the last fiscal year this Division inspected, for its own Bureau and six other Bureaus of the Navy Department, nearly 8,000,000 lb. of engineering and other material. This inspection was conducted by a force of 306 naval officers and civilian assistants who visited more than 2,000 manufacturing establishments in this work.

Fuel and Personnel. The Fuel and Personnel Division is in charge of Commander H. A. Stuart, U. S. Navy. During the greater part of the year, it was headed by Commander N. H. Wright, U. S. Navy. Fuel oil, gasoline, and lubricating oils are vital essentials of modern navies, hence, the work of this Division is of fundamental importance, especially as the Navy is now hard pressed in its effort to retain the naval oil reserves in California. However, all of the Navy's new ships are oil burners, since, during their lifetime, fuel oil for them will not fail.

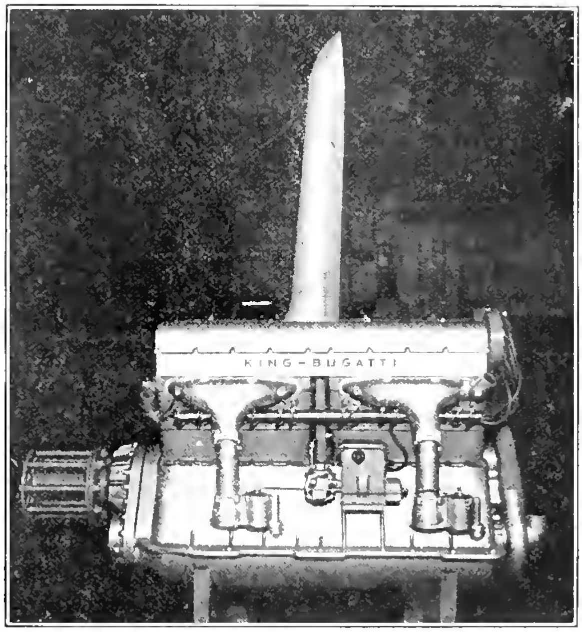

Fig. 8 King-Bugatti Aeroplane Engine, 16 Cylinders

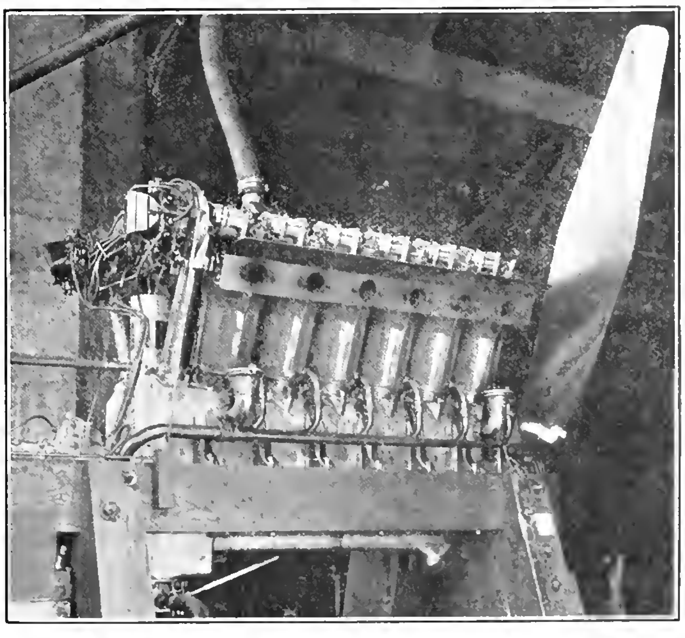

Fig. 9 Liberty Motor, 12-Cylinder, 400-hp., Standard U. S. Aeronautical Engine

This Division covers a broad field. During the last fiscal year it assisted in extending the coaling facilities in our ports and in making a comprehensive survey of the low-volatile steaming coals with the view of locating mines capable of furnishing suitable fuel for the Overseas Transportation Service. It modified the

naval specifications to permit the use, for a time, of a considerable percentage of Mexican distillate, and made preliminary investigations for establishing specifications for heavy fuel oil for transports and cargo carriers. Further, it coöperated with various Government agencies in the adoption of standard specifications for aviation gasoline.

Division of Repairs. The Division of Repairs is in charge of Commander W. A. Smead, U. S. Navy, who has been for some months in Europe. In his absence, it is headed by Lieutenant Commander Bruce.

During the war this Division has had its hands full with the repair work for the Fleet and the vessels operated by the Navy—a total of nearly 2000 by the end of last June. However, it measured up fully to its work, and no vessel of importance has been laid up for repairs.

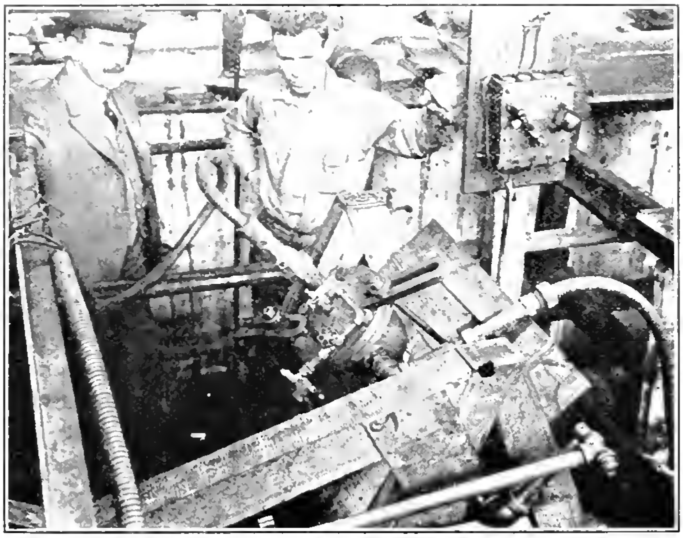

Fig. 10 Steam Trap Mounted on Rocking Platform to Determine Its Behavior on a Vessel in a Seaway

Fig. 11 Microscopic Examination of Large Metal Object. Microscope and Camera Attachment Arranged for Making Photomicrograph of a Broken Shaft Coupling

Since we had more than 250 vessels in European waters, the problem of their repair and maintenance was not simple. Spare parts had to be ready, and material wants anticipated. To this end, a stock of the most important engineering material was provided by this Division—some in this country, but the greater portion at the foreign bases—and its location and use so thoroughly systematized that it could be shipped upon cable advice.

For this work of repairs and supply, the Navy established a total of five major bases—three in France, one in Great Britain, and one at Gibraltar. There are also two minor bases, in or near the Mediterranean. The facilities of these bases were reinforced by those of six Repair Ships.

As illustrating the resources of the Repair ships—the retubing of boilers of a destroyer was undertaken without interruption of her regular patrol and convoy duty by working on one side of the boiler during her 5-day overhaul period, and completing the other side during the following period, and so on until all were finished—the vessel meanwhile being capable of 25-28 knots speed.

Division of Aeronautics. The Division of Aeronautics is in the charge of Commander A. K. Atkins, U. S. Navy. The work of this Division covers aircraft machinery generally, engineering design for this purpose, and the generation and supply of gas for observation balloons and dirigibles.

The marked military advantage to be gained by having but one type of airplane motor prompted the Navy Department to adopt the motor used by the Army. All Liberty motors for the Navy are, therefore, obtained through the Aircraft Production Board. Orders have been placed for more than 4000 of these Liberty engines, delivery to be completed by January 1, 1919. Of this number, about 1300 were received by the end of the fiscal year, and distributed to various naval air stations in this country and abroad. There have also been purchased about 500 Hispano-Suiza engines for use at naval air stations in this country.

In general engineering design the Bureau has done much work, especially with regard to the application of the Liberty motor to seaplanes. This work covered starters and priming devices; the development of a flow meter, pneumatic spark arc throttle controls, and an oil-cooling system.

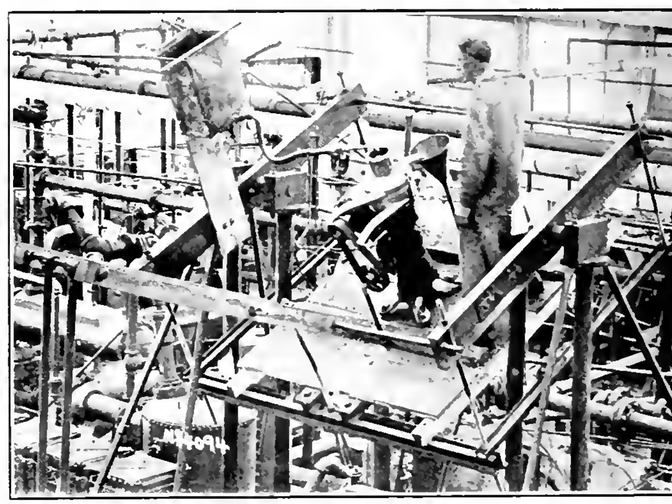

Fig. 12 Centrifugal Oil Purifier Mounted on Rocking Platform During Development Trials

Division of Logs and Records. The Division of Logs and Records is in charge of Commander W. W. White, U. S. Navy (Retired). In the effect of its work on marine engineering design and progress, the field of this Division is of great importance.

Its main functions are: the checking-up and review of the engine-room logs of naval vessels; the compilation and issuance to the seagoing personnel and naval training schools of Bureau pamphlets relating to the care and management of machinery on shipboard; the preparation and issuance to the naval service of the Confidential Bulletin of Engineering Information; and the filing and indexing of all important data regarding engineering matters, with especial reference to naval vessels.

The Electric Drive for Battleships

In those stormy days toward the end of the Civil War, Isherwood, that master engineer, designed for the United States Navy the 17-knot cruisers *Wampanoag* and her sister, which—as their trials proved—were incomparably the fastest ships, naval or merchant, at that time in the world. The jealousy and ignorance of those days of semi-sail power brought down on him a storm of

criticism, and ultimately the great Engineer-in-Chief was forced to see his peerless ships rot at their moorings.

In the years since then there has been no fit comparison with this shameful episode in our naval history, except, in less degree, the similar storm which burst on the head of the present Engineer-in-Chief, when, with high courage and far vision, he urged the introduction of the electric drive for the propelling machinery of battleships and battle cruisers.

The crux of the opposition lay apparently in commercial reasons. It is true that some eminent engineers in civil life, who had no financial interests in the matter, were wholly sincere in voicing their disapproval of what—with their inadequate knowledge of naval conditions—seemed to them a hazardous venture. But, as to others: what the basic reason for the war waged on the Bureau of Steam Engineering in opposition to the electric drive was, may well be left to those who made the attack.

Throughout the controversy the Engineer-in-Chief held unwaveringly to his decision. No arguments had power to turn him, for he had—what his critics lacked—detailed knowledge, both of naval requirements and of the performance of electricity as a driving power in naval vessels. About seven years before, the naval collier *Jupiter* had been thus equipped by his predecessor in office, Rear-Admiral Cone. As soon as she was completed, Admiral Griffin sent the Assistant to the Bureau—Commander,

FIG. 13 1ST I. P. CYLINDER OF S. S. "SANTOS," NAVY YARD, PHILADELPHIA, MAY 3, 1918

now Rear-Admiral S. S. Robison—to the Mare Island Navy Yard, with orders to try the *Jupiter's* machinery at sea in every conceivable way. The report of this officer was exhaustive, and, therefore, Admiral Griffin knew, in every detail, just how the electric drive would act in all conditions. So, from an engineering viewpoint, the contest was an unequal one.

The contract trials recently of the *New Mexico*—the first of our battleships to be fitted with the electric drive—have confirmed fully the judgment of the Engineer-in-Chief. She was tested in many more ways than her contract called for, and, in all, she has shown herself, not only wholly efficient, but—in her system of propulsion, her maneuvering power, and her underwater protection—the leading battleship of her day in the navies of the world.

I need hardly say here that the steam turbine has replaced the reciprocating engine for battleship propulsion. And, I need scarcely add that the combination of a turbine—whose maximum economy is shown at 2000 revolutions or more—and a propeller—which, in a battleship, should not exceed 180 to 200 revolutions—presents a rotational problem of some complexity.

In the electric drive the turbine operates an electric generator instead of a screw propeller, and the electric power thus developed is transmitted to motors on the propeller shafts, in much the same way as electric power is transmitted on shore. In other words, there is a central power plant—composed of boilers, turbines, and electric generators—and the power is taken from this plant to the motors on the screw shafts.

This installation possesses an advantage over the direct or geared turbine drive, in that a backing turbine is not required. The reversing is done through the motors with the same ease and certainty as in any other electric-motor installation, and with the further advantage that full power can be utilized in backing.

The elimination of the backing turbine is a matter of prime importance, since most of the accidents to turbine-driven vessels of the Navy are due to it. For example, the dreadnaught *Arizona*,

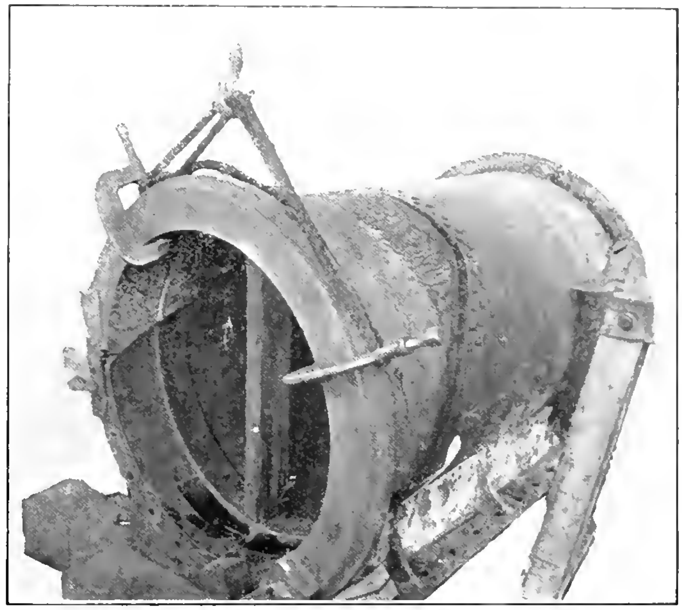

FIG. 14 1ST I. P. CYLINDER OF S. S. "SANTOS," NAVY YARD, PHILADELPHIA; READY TO WELD, MAY 29, 1918

FIG. 15 1ST I. P. CYLINDER OF S. S. "SANTOS," NAVY YARD, PHILADELPHIA; FINISHED AUGUST 15, 1918

in her first trip from New York, had been making a very fine record in straight-away steaming, but, when she began maneuvering, one of her turbines came to grief, and she had to limp back to the New York Navy Yard, with a big job of reblading to be done.

NAVY YARDS AND SHORE STATIONS

As to the immense amount of work carried on at the New York Navy Yard under the direction of Rear-Admiral George E. Burd, U. S. Navy, Industrial Manager, since April 6, 1917, Admiral

Burd and the officers serving with him have had charge of the conversion and repairs, in all departments—including the mounting of batteries in many cases—of a total of 723 vessels of all classes. Much of this work was under cognizance of the Bureau of Steam Engineering.

In addition to this, the propelling machinery—in whole or in part—of these battleships has been building there, and considerable other new construction work of a minor character. Further, there has been a great deal of electrical and radio work for vessels of all classes. The number of men employed—including the clerical, drafting, and sub-inspector force—was about 4,900.

Naval Experiment Station at Annapolis

The Naval Experiment Station at Annapolis does much of the marine-engineering research and experimental work of the Bureau.

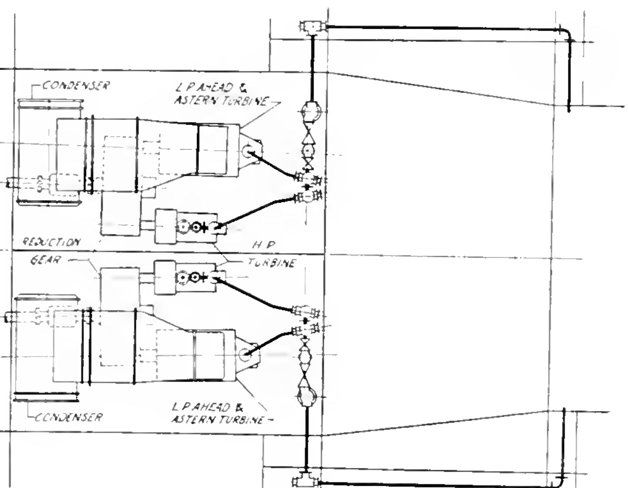

Fig. 16 Battleships, Diagrammatic Plan of Turbine Drive with Reduction Gear Showing the Arrangement of Machinery

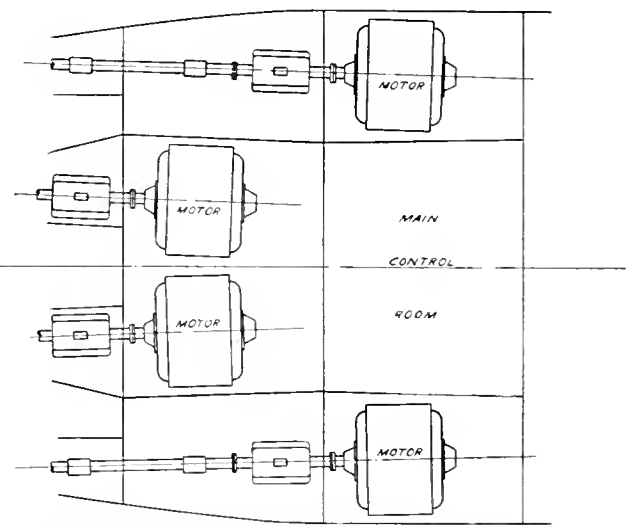

Fig. 17 Battleships, Diagrammatic Plan of Electric Drive Showing the Arrangement of Motors

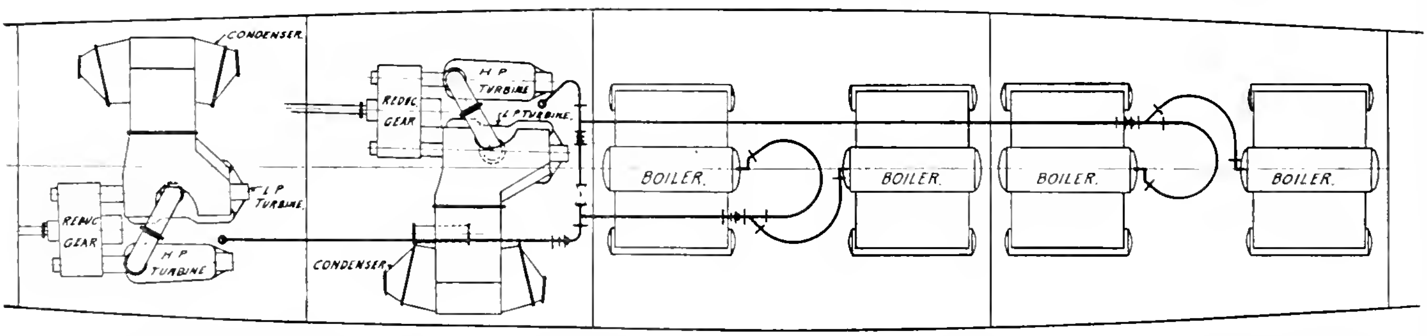

Fig. 18 Destroyers, Diagrammatic Plan of Turbine Drive with Reduction Gear Showing the Arrangement of Machinery

The Head of this Station is Rear-Admiral T. W. Kinkaid, U. S. Navy.

The services of this Station are of the greatest value, not only in the designing work of the Bureau, but in the maintenance of the machinery of the Fleet. Its chief function is the prosecution of research on, and making tests of, appliances, materials, and methods which relate to the propelling plants of naval vessels—such as forced-draft blowers, pumping machinery, feedwater heaters and coolers, refrigerating machinery, steam turbines, condensers, evaporators, boilers, coal and oil fuels, packings, and so on. The Station's activities also include much work in the metallography of steel and other metals.

Fuel-Oil Testing Plant

The Fuel Oil Testing Plant at the Philadelphia Navy Yard has also done a very considerable amount of valuable work. Its present head is Lieutenant A. M. Penn, U. S. Navy. Its field covers burners, air registers, the refractory linings for furnaces, furnace insulation, and other similar matters.

During the last fiscal year, in order to obtain comparative data of boilers of various types, a test of the White-Forster boiler was conducted at this plant. The results show that express type boilers of this kind, having a large amount of heating surface and a thick tube bank, are even more efficient at from low to moderately high rates of combustion than the straight-tube boilers now used so extensively in our Navy, but that they are slightly less efficient at very high rates. The express type has advantages also in the saving of weight, original cost, and cost of upkeep.

Repair of the German Merchant Ships Damaged by the Vandalism of Their Crews

The almost incredibly rapid repair of the German merchant vessels lying in our ports and seized by our Government when we entered the war, makes one of the most striking and dramatic stories in the history of naval engineering.

There were, in all, 103 of these German ships seized by our Government. Of this number about 50 were turned over to the Navy by the Shipping Board for Repairs. The major damage inflicted was the breaking of cast-iron parts of the main engines, chiefly the cylinders. But, in addition, some connecting rods, piston rods and boiler stays were sawed through, boilers were burned out by dry firing, and there was much minor vandalism.

The chief problem, however, was the repair of the broken cylinders, some of which were more than 9 ft. in diameter. The Bureau estimated that—with such facilities as were available for this heavy work—it would take at least eighteen months to replace the damaged cylinders by new ones. Meanwhile, there was bitter need of rapid transport for our troops to France. On the removal of that crisis, there seemed to depend the salvation of Christendom.

At this juncture, Captain Earl P. Jessop—then Engineer Officer

of the New York Navy Yard—recommended that repairs be made by welding, and, in this recommendation, he was heartily supported by Rear-Admiral George E. Burd, Industrial Manager of that Yard. The Engineer-in-Chief at once ordered Captain Oscar W. Koester, Assistant to the Bureau, to New York to investigate the situation fully. As the result of his report, the Bureau immediately issued orders to make repairs, where possible, by electric or oxy-acetylene welding, and where welding was impracticable owing to the location of the break, to resort to mechanical patching—that is, to "soft patches" which are secured by body-bound bolts.

From this stage onward, the repairs were supervised personally by Captain Koester, who, in his resourceful ability and driving power, is unsurpassed. His work went on night and day, and in five months he traveled about 14,000 miles in railroad trains from one Navy Yard or private plant to another along our Atlantic Coast. At the expiration of that period, his huge work was done and the ships were ready for service.

The rapidity of getting these ships ready for service was facilitated by one other action. On many of them, in addition to the damage done by vandalism, extensive repairs were necessary, owing to their deterioration from long idleness. As the necessary overhaul and all routine repairs could be made by a capable naval crew under able officers, the Engineer-in-Chief laid the matter before Admiral Benson, Chief of Operations, with the request that the ships be fully commissioned before repairs were begun. This was done, and thus, while the welding operations were in progress, the ships were prepared in all other respects for sea.

One other feature of this matter deserves comment, and that is the military value of this work in the transport of troops. These fifty ships were in service for about a year before hostilities ended, and this is approximately the time saved in these repairs by using welding methods. Twenty of these vessels can carry about 70,000 troops in one trip, and ten round trips a year is a conservative estimate of their performance. Representative Young of North Dakota, who crossed the Atlantic in the *Leviathan*, stated recently in the House that she had transported more than 99,000 troops up to August 20. So, it may be justly claimed that the rapidity of these repairs had a marked effect on the early end of the fighting in France.

LONG-RANGE HEAVY NAVY GUNS WITH RAILWAY MOUNT

By Lieut.-Com. D. C. Buell,[1] U. S. N. R. F.

The history of the work done in completing a mobile battery of naval guns in record time for service in France forms a remarkable record, even in an organization as noted for great achievements as the American Navy.

Owing to a change in the characteristics of certain battle cruisers, a number of 14-in. 50-caliber guns, originally built for these ships, became available during November 1917 for other service.

It was felt that if these guns could be placed upon railroad mountings they would prove a valuable adjunct to our artillery forces, since they throw a 1400-lb. projectile at a muzzle velocity of 2800 ft. per sec., giving, at high elevations, an effective range of nearly 30 miles. They throw a heavier projectile with greater accuracy and to a greater distance than any gun previously placed on mobile shore mounts.

But little preliminary discussion was necessary before the plan to use these guns in a naval railway battery was approved, and on December 26 last the Navy Bureau of Ordnance instructed the Naval Gun Factory at Washington to prepare plans and specifications for the project.

The final plans and specifications not only for the mounts, but for the locomotives, cars, and other equipment necessary to form a complete land expedition, were completed in less than 30 days, being ready to submit for bids on January 25.

The plans and specifications called for five 14-in. railway gun mounts, six locomotives, and six complete trains of cars—75 cars in all.

On completion of the plans, proposals were immediately sent out by telegraph to the leading manufacturers of the country calling for an opening of bids on the morning of February 6.

The first bids were rejected because time of delivery was not satisfactory, but as a number of manufacturing plants had representatives present when bids were opened, a better understanding of the project was possible.

A second opening of bids was set for February 13. The result of this opening was very pleasing and the contract was awarded on the afternoon of February 13; and on the same evening the contractors began the work of gathering together the necessary material for the project. The date of delivery of gun cars and locomotives was set by The Baldwin Locomotive Works for June 15, and the Standard Steel Car Company undertook to deliver the cars and special equipment by this same date.

In spite of the fact that The Baldwin Locomotive Works, noted for making, perhaps, the fastest manufacturing schedules in the country, had set June 15 as their earliest date, Mr. Vauclain and his organization speeded up this project so that the first mount was completed and moved from the Baldwin shops on the morning of April 25, 72 days from the date bids were opened and 20 days ahead of the Baldwin schedule. This mount was taken to the Army Proving Ground at Sandy Hook for its test firing; the tests were entirely satisfactory.

The last of the mounts was finished and delivered on May 25, and practically all of the cars and special equipment delivered for shipment by June 1; hardly 100 days from the time bids were opened, and only 155 days from the time the project was first considered.

A very impressing feature of the work was that there was practically no change in design necessary during construction. The original drawings were final drawings in almost every case.

Army officers who viewed the tests of the first gun were so impressed with its performance and with the speed with which the project was being completed, that the Navy Bureau of Ordnance was requested to build for the Army three additional and identical mounts.

Requisitions were prepared and material ordered for these three mounts on May 18. The first Army mount was finished complete and ready for shipment on July 17 and the second and third on July 25.

When it was seen that the first three mounts built for the Army were nearing completion, the Navy Bureau of Ordnance was requested by the Ordnance Department of the Army, on July 18, to build another lot of identical mounts. Work on these second three mounts was pushed, and the first was completed on September 16, and the remaining two a few days later.

It is to be regretted that conditions were such that these mounts built for the Army were not shipped to France in time to be erected and put into active service.

The original understanding was that the Naval Battery would operate with the British Army. By April 15 enormous quantities of material had arrived at Philadelphia Navy Yard and shipment could have commenced at that time. On May 15, with the completion of the entire project no more than two weeks distant, and no definite decision from the British as to the shipment of the guns, due to the fact that the German drive had threatened channel ports, the expedition was offered to General Pershing for use with the American Army.

On May 23 General Pershing cabled, requesting immediate shipment of the entire expedition to St. Nazaire, France. The shipment of the equipment to France was delayed because of the fact that the German submarines, which operated on this side of the Atlantic, torpedoed the S.S. *Textile*, inbound to take the guns and

[1] Bureau of Ordnance, Washington, D. C.
Presented at the Annual Meeting, New York, December 1918, of The American Society of Mechanical Engineers.

the girders to France, so that the first shipment was not made until June 20.

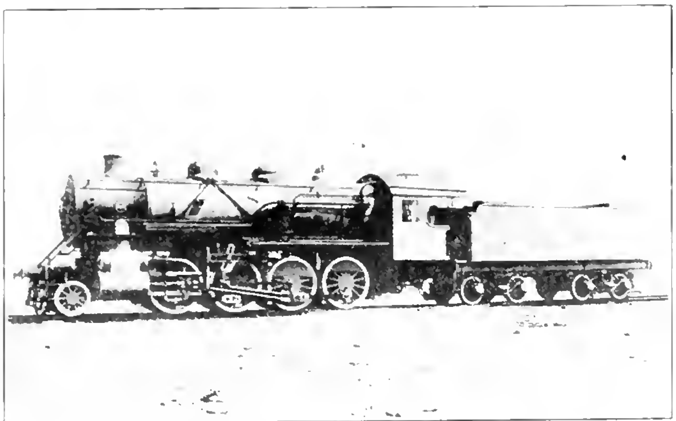

FIG. 1 ONE OF THE SIX LOCOMOTIVES CONSTRUCTED FOR THE RAILWAY MOUNT EXPEDITION
Weight of Locomotive 83 Tons. Weight of Tender 56 Tons

14. The last train left for the front on September 21, and arrived at the base on September 22.

The first gun was fied against the Germans on September 5—less than 250 days from the time the project was first thought of.

Too high commendation cannot be given to those who conceived this project. The entire equipment operated in a highly satisfactory manner, and practically without change from the original design. The question as to the guns being too heavy to transport over French railroads, proved groundless.

The pit which the French at first criticized, proved a very valuable feature when the guns were fired at a fixed target for any length of time.

It was suggested by the French that if a similar type of mount could be devised for use where it was desired to bring the gun into action quickly, it would obviate the only possible objectionable feature of the first mount. It is interesting to know that the Navy Bureau of Ordnance, anticipating this requirement, had already designed and was building another battery of 14-in. mounts before the armistice was signed.

These new mounts were designed to be fired directly from the track, at all elevations, without any preliminary preparation

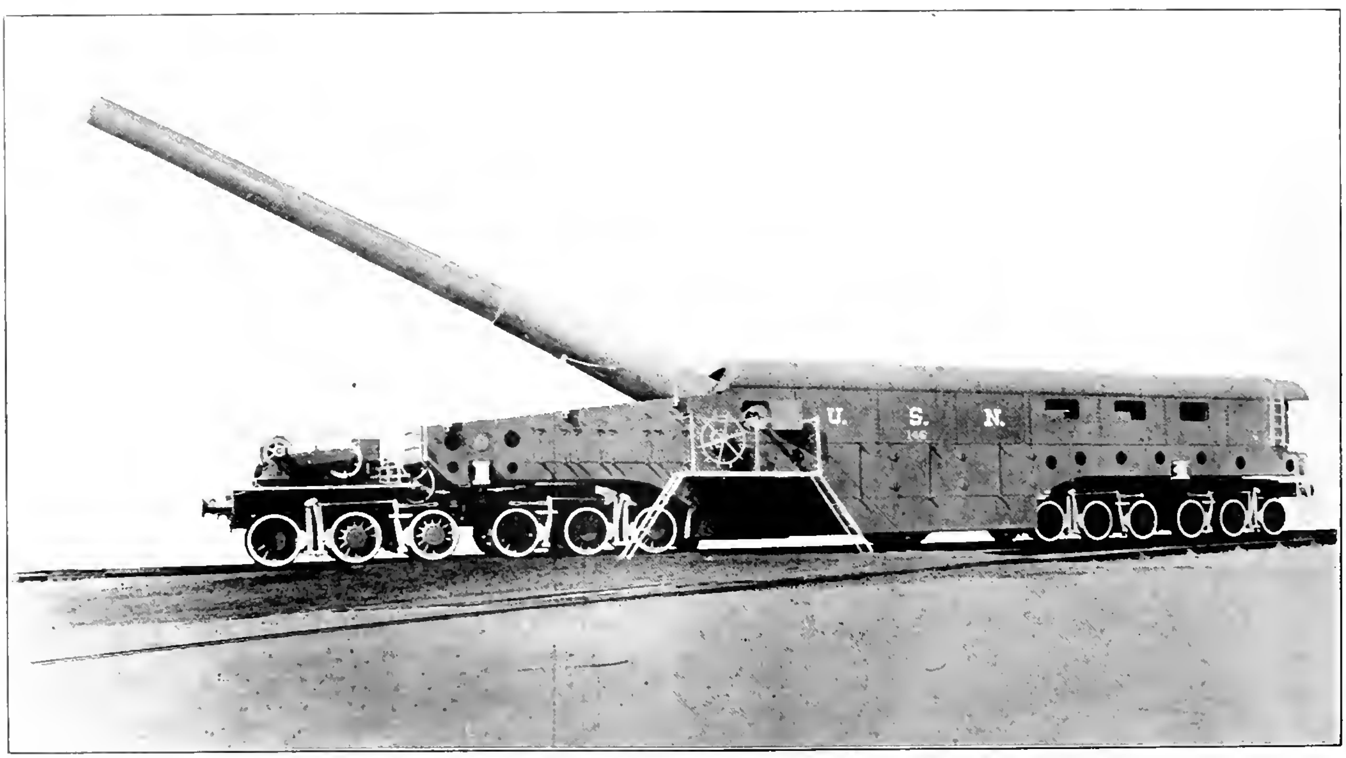

FIG. 2 ONE OF THE 14-IN. NAVAL RAILWAY GUNS DESIGNED, BUILT AND PUT INTO OPERATION BY THE BUREAU OF ORDNANCE OF THE NAVY DEPARTMENT

This first ship was followed by two others on July 4. The final shipment of spare parts, extra guns, etc., was made on July 21.

Anticipating the need of skilled men for erection work in France, 200 experienced railroad mechanics and operating men were selected from the 40,000-odd bluejackets at the Great Lakes Naval Training Station, and sent to France a little before the first ships of material sailed.

The first shipment arrived at St. Nazaire on July 8; the second and the third on July 21.

The locomotive and car erection began July 20. The erection of the first gun was begun July 30. The first gun train was completed and ready to leave St. Nazaire on August 11. The first two gun trains left for the front on August 17 and 18, respectively.

The first gun mount was ready 12 days after the girder was unloaded from the ship. The first two trains were ready 22 days after erection work started.

Trains 3 and 4 were completed, equipped, and loaded September

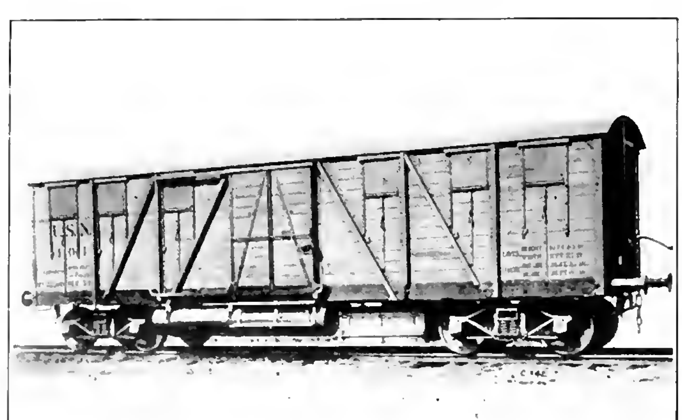

FIG. 3 ONE OF THE 75 CARS CONSTRUCTED FOR THE RAILWAY

whatsoever; had they been required they would have been ready to ship to France by February 1919.

As far as can be ascertained, there were no finer or more accurate-shooting guns in the war than these first 14-in. mounts.

Had the new mounts been added to and consolidated with the first expedition, it would have been difficult for any nation to have conceived and executed a finer battery of guns than the U. S. Naval Batteries.

After the reading of his manuscript Commander Buell showed some slides and a reel of moving pictures illustrating the details of working out the project. At his request Mr. George A. Chadwick, Mem.Am.Soc.M.E., the designer of the gun, then gave interesting particulars regarding weights, reactions, dimensions, etc., which are embodied in the following paragraphs.

Figs. 1 to 5 give a slight idea of the magnitude of this work. The gun complete weighs about 550,000 lb. The shells weigh nearly 1500 lb. each and the powder charge for a shell 484 lb.

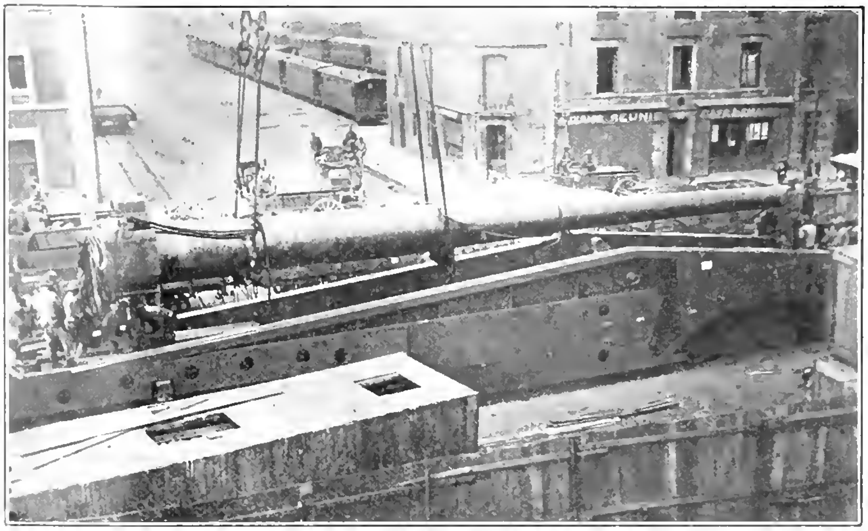

Fig. 5 Placing Gun on Girder for Transportation to Ship

There was considerable question as to what would happen when the first gun was fired, and some of the spectators even suggested where the girder would break in two. Nothing happened, however, and the work was continued without any difficulty.

The gunwork was adapted to the mount with very little change from battleship design. This allowed the use of considerable material that was on hand. A view of the girder is shown in Fig. 3.

Fig. 4 A Gun Girder Under Construction in a U. S. Naval Gun Factory

The truck axles were designed to withstand a maximum axle load of 63,000 lb. The kinetic energy of the gun is about 4,000,000 ft-lb., which is absorbed through a hydraulic brake in the recoil of 44 in. in the slide, and when firing on the rails the movement to the rear along the tracks is about 26 ft. When firing from a pit the load is transmitted to foundation members in the form of a heavy grillage construction of castings and structural-steel shapes, the load being limited to about 4 tons per sq. ft., which so far has been found to be satisfactory.

Some idea of the difficulties which arose in assembling the guns and locomotives on the other side may be gathered from the fact that it is necessary to have everything on the ground before starting to build. For this reason the material piled up in an unbelievable manner. Two switching engines had to be working day and night removing loads to the yard, unloading them with the crane and making the various moves necessary to clear up the work.

THE ENGINEERING OF MAN POWER

Keynote Sessions of the Annual Meeting. Papers and Addresses of Vital Interest

It was quite evident from the attendance, the general interest and the lively discussion which attended the reading of papers on Thursday morning and afternoon at the Keynote Session of the Annual Meeting of the Society that the Committee on Meetings had arranged a program which was in accord with the present trend of affairs in the industrial world as well as in society at large. That the Engineering of Man Power should have become the subject of a keynote session of The American Society of Mechanical Engineers is indicative of a point of view of that very perplexing problem of industrial relations which the war, and particularly the closing of the war, has forced upon a newly-awakened consciousness in the world at large.

Opening Addresses by Dr. Ira N. Hollis and Dr. L. S. Rowe[1]

The morning session was opened by the Chairman, Vice-President Plunkett, who introduced Dr. Hollis, Past-President of the Society, who had been asked by the Committee on Meetings to make the introductory remarks. Dr. Hollis recalled the incident of a year ago when members of the Society stood with bowed heads in prayer that the war upon which America had entered would be victoriously ended before a year had passed. A modern miracle, he said, had been performed by America in sending across the seas two millions of men—two millions of every nationality, fused together in the melting pot which is America and united in a common purpose and forming the finest army, morally, known to history. When these men return, he asked, are we going to measure up to their ideals of what America ought to be?

The old estimates of other countries of a dollar-mad America had been shattered by this war, as was evidenced by the free-will contributions of enormous sums to the Red Cross, to the United War Work Campaign and to other causes. "I believe," he said, "that there is one phrase which expresses American ideals,

[1] Assistant Secretary of the Treasury, Washington, D. C.

and without which none can ever understand America. . . . Service to Man. I would put that forth as the motto of America —Service—and anyone who interprets our civilization . . . through that one word will have a complete understanding of American ideals. The changing character of the papers presented in the past ten years before the Society is an indication of an appreciation and understanding of true American ideals, for as we study them, we find that they have turned more and more toward an exposition of the opportunity of the engineer to serve mankind."

Dr. Hollis' address was followed by one by the Assistant Secretary of the U. S. Treasury, Dr. L. S. Rowe, who spoke on The Engineer in Foreign Service. Dr. Rowe refered to his observations of American and other engineers in the countries of Central and South America where he had spent much time and pointed out some of the failings of the American engineers. These were not, he said, because of lack of training, or any lack of grasp of principle, or lack of inventive genius or ability to meet new situations, but because at times American engineers in foreign service do not as fully appreciate the larger responsibilities and the larger representative capacity which they must assume when engaged in great public works abroad.

One defect, said Dr. Rowe, was a certain impatience and unwillingness to make a real effort to teach a native population how to become efficient laborers. The engineer may exploit labor, or he may perform a great economic service to the country in which he is operating and create ties and influences which will be an important factor in determining the general attitude of that country toward America. In so doing the engineer is performing a diplomatic service for the United States. A further shortcoming of the American engineer abroad is his impatience to return home. The American engineer, like the American banker, or salesman, does little to learn the language or to make local acquaintances or to get into a closer contact with the people of the localities in which he is operating.

There is no representative who touches the life and progress and well-being of a country as closely as the engineer, and therefore it is of vital importance that in the early training of an engineer everything should be done to prepare him for foreign service. He should know considerable of economics, of government; and he should learn a language with a greater degree of thoroughness than he learns at present in our universities. He should be encouraged in foreign travel to the extent that he might have the benefit of a scholarship for that purpose. Thereby a group of engineers might be trained for foreign service. Here rests a great national responsibility on the engineering profession.

Dr. Rowe's address appears in more complete form elsewhere in this issue.

Industrial Organization as It Affects Executives and Workers

Charles E. Knoeppel then presented his paper, Industrial Organization as It Affects Executives and Workers.[1] From a studious survey of his experience as an executive the author emphasized as essentials in the formulation of definite laws of organization: The necessity of having an objective in the mind before beginning to work; the exclusive concentration of each man to definite functions; the avoidance of confusion and conflict of authorities; the proper division of departments in order to insure that each executive has complete control of all the factors affecting the success of his function; the creation of divisions which will develop specialists; the provision for permanency by training men to fill the positions of their superiors; the exact definition of the duties of each employee and of his relations to the others; the logical selection of personnel according to individual qualifications; and the creation of a standard manufacturing practice.

Valuable suggestions were also given in regard to the question of establishing an efficient administration. Delegating authority to subordinates, overlooking minor details, listening to wise counsel and arousing initiative in employees were recommended as important points in the exercise of industrial authority.

[1] For abstract of paper see December Journal, p. 1031.

In a written discussion of Mr. Knoeppel's paper, John F. Grace said that the 15 conditions stated in the paper were almost axiomatic, but that their application was a gigantic task for executive genius. To this end, pictures and graphs should be applied as in the manner of good advertising to instruct the workers, rather than texts. The lack of definite instruction to each worker, which had been mentioned as a major cause in the breakdown of organizations, seems largely due to the inability of managers or systematizers to define and isolate duties which are constantly overlapping. Any radical change of system affecting the majority of workers should be explained at a general meeting of the employees of the department or plant affected, by someone who understands the object and method.

C. W. Johnson, in an oral discussion, spoke of the keynote of justice, fairness in an active way to every individual in the organization. A. C. Fleckenstein[1] said that engineers engaged in production could help immeasurably the advance of industrial and efficiency engineering methods by creating in the mind of the owner of the plant a proper regard for the services of the apparently non-productive industrial engineer, an investment in whose services would render a large financial return.

Standardization and Administration of Wages

A paper by Earl Dean Howard[2] and Henry P. Kendall entitled Standardization and Administration of Wages, was read in abstract by Secretary Rice in the absence of the authors. The paper first gives particulars of the administrative machinery available before the war for dealing with industrial relations, and then of the governmental agencies since developed for that purpose. The authors then set forth certain general principles which they believe should be followed in dealing with labor problems in the future. The term standardization does not necessarily mean uniformity of wages, hours or conditions of work, but the determination of these conditions according to general principles, the justice of which is universally acknowledged. Say the authors: "The regulation of industrial standards by joint boards as suggested has the great advantage over the present system in that it eliminates at least three-fourths of the cost of friction between the particular employer and his employees. Each employer then adopts the standards which are current in his trade and knows that all his competitors are on the same basis and have no advantage over him. Even under our present system, the chief objection to any one employer's increasing wages lies in the fact that it comes out of the profits unless the increase is general among his competitors, when it is shifted to the consumer of the product. It is easy to foresee a time when the public and not the employers will have the chief interest in opposing wage advances."

Standardization is increasing in the larger industrial establishments. The administration of industrial relations, especially by a skilled person specialized for the work is no longer an experiment. It is reasonable to expect that organization of employees, fostered by the employer and given full opportunity to function legimately in matters which touch the interests of employees may develop into constructive agencies whose criticisms and suggestions may be of great value in improving the efficiency of the business. To make this plan truly successful, however the management must decide to give labor a fair share of the efficiencies and economies realized.

A further abstract of the paper is given later in this report.

In discussing the paper, H. F. J. Porter spoke of the work which Mr. Howard had done in introducing in many industrial plants methods of bringing employer and employee together with a representative of the public. These methods have been introduced into New York in the cloak and suit industry, composed of some 80,000 employees. On the Board of Control organized for the consideration of questions arising out of industrial relations are

[1] Richmond Radiator Co., New York City.

[2] Executive Secretary, Committee of Industrial Relations, Washington, D. C.

represented a group of labor unions and a group of manufacturers. These two elect a representative of the public. In large industries today there are many such organizations. A meeting to discuss the merits of this type of organization is being planned in conference with Mr. Howard, Frank P. Walsh and Hon. William H. Taft. This conference will probably result in a public meeting to put before the people of the country the work of these organizations and their recommendations.

Non-Financial Incentives in Industry

The last paper scheduled for the morning was by R. B. Wolf on Use of Non-Financial Incentives in Industry.[1] The sincerity and earnestness of Mr. Wolf's words won for him the admiration and approval of his audience, awoke in them an uncommon interest and stimulated an inspiring discussion which had to be carried over into the afternoon session, thereby delaying the afternoon schedule by fully two hours. Mr. Wolf confined himself to the subject of non-financial incentives to an extent which led some of his hearers to imagine that he had no faith in financial incentives, a misunderstanding which was subsequently cleared up by the speaker. That man does not do his best work for hire was Mr. Wolf's basis for the non-financial incentive; that is, interest in work, "the joy of the working." His plea was for the utilization of the creative agencies of labor; and to prove the practicability of their utilization he gave examples of what had been accomplished in mills under his management where interest in the work had been stimulated by "progress" records of individuals and by an appeal to the natural intelligence of the workman. To quote from a closing paragraph of the paper: "We should never lose sight of the fact that the degree of conscious self-expression which the workman can attain is in direct proportion to the ability of the organization to measure, for his benefit, the impress of his personality upon it. The most democratic industrial plant, therefore, is the one which permits the fullest possible amount of individual freedom to each member, irrespective of his position, and at the same time is so sensitively adjusted that it reflects immediately the effects of his actions. If his actions result in injury to others he will see that as a part of the whole he, himself, must also suffer."

The discussion of the paper was opened by Walter N. Polakov, who took occasion to warn the members that they should not get the impression that financial incentives were not important or even superfluous as long as non-financial incentives are at work. To illustrate his point he showed on the screen three charts indicating the preventable losses in a power plant. In chart 1, with neither financial nor non-financial incentives, the loss amounted to over 30 per cent. With non-financial incentives at play in chart 2, the loss had been reduced to 17 per cent, while in chart 3 with both financial and non-financial incentives at work the preventable losses had been wiped out. W. E. Pulis showed some slides of a similar nature in which the same facts were represented. Later in the afternoon, in reply to Mr. Polakov, Mr. Wolf said that the reason the non-financial incentive records shown by Mr. Polakov did not show as great a saving as was shown when a bonus was attached was because he had not tried the plan of giving the men the record of their accomplishment without the bonus attached to it. Without deprecating bonuses entirely, Mr. Wolf was of the opinion that they should be carefully considered. Men both union and non-union had said to him, "We don't like to be bribed to do a good job. We would like to have the privilege of doing a good job without being bribed to do it."

Irving A. Berndt,[2] in a written discussion of the paper said that he was particularly impressed and in accord with what Mr. Wolf had said concerning the necessity of providing workers with environments which attract, and providing incentives inherent in the nature of the work itself. This was fundamental and basic. "Were I to add any thought to this," he said, "it would be that the responsibility for this lies with the individual employer, manager and executive and should under no circumstances be passed on to society or to the worker himself."

Being confronted with the problem of reducing supplies taken from storerooms in a large plant—supplies used for maintenance and repair—Mr. Berndt found it possible to secure interest among the men calling for them by placing at the storeroom window a list of current prices and a weekly bulletin telling how much the supplies used by each man or group had cost, comparisons being given. The two simple records stimulated interest and the desired result was secured. He had never found a foreman, he said, unresponsive to confidence placed in him by showing him records of costs, performances and even profits. He would not consider a monetary incentive properly applied unless it included a plan for keeping each man advised of current progress and also giving him a written statement of results.

Afternoon Session—Continued Discussion of Mr. Wolf's Paper on Non-Financial Incentives

The session of the afternoon was presided over by Vice-President John Hunter, who called for additional discussion of the Wolf paper. Henry L. Gantt said that the paper was an important contribution because it emphasized democracy in industry, and also that there could be no democracy in industry unless there was common knowledge of what was going on. Mr. Wolf had obtained remarkable results by letting every man know what he was doing and what was expected of him. It was too often true that the employer did not know exactly what his employees were to do. The discussions of Messrs. Polakov and Pulis had indicated what could be accomplished when it was known exactly what men should do. In settling the problems confronting employer and employee each concern is going to solve its own by knowing more about the conditions in its own shop and what is hampering the workmen there.

Richard A. Feiss thought that there was danger of interpreting Mr. Wolf's paper as a condemnation of financial incentives. Both financial and non-financial incentives have their place and must be taken into consideration. There are no cure-alls in industry, and failures in the application of so-called efficiency methods have grown out of a loss of perspective. The object, after all, is to obtain the best possible result from the human element in industry, and that involves a psychological question. The problem of employment will be solved only by maintaining a broader vision, by remembering that the human being is a human being and must be studied from all points of view and under varying conditions. He said that Mr. Wolf's paper called attention to a single element in management and that it, with all the other elements under the existing situation, must be taken into consideration when dealing with the complex psychological question of industrial relations.

A. L. De Leeuw said that the lasting growth of labor can only be caused by making labor grow from the inside out. The effort must be made by the laboring man, and not by the employer. The employer has only helped labor in general, but has not caused it to grow. Labor has taken the stand that it can grow only by antagonizing the employer, who, at one time, held this same view of labor. Something should be done to make labor start a growth or development of itself in the proper direction. If labor has not seen these facts, should not some one hold out the hand and invite labor to move in the right direction? Has not the time come when the engineer should get in touch with labor and invite it to discuss labor questions from a standpoint of pure and simple engineering, dropping all ideas of malice, and presenting the idea that a true bargain is one which benefits both parties? "Should there not be a third party," he said, "more or less disinterested, or rather, interested in the welfare of both, who will hold out the hand to labor and invite it to develop itself, to make an organic growth from the inside outward? Would it not be well if some engineering society were to invite labor into its counsel and see that a proper organized effort can be made for labor to look at the questions, not only of its own development, but of the development of industry as a whole, making labor to realize that no real benefits can ever come to it and be lasting unless similar benefits come to the industry as a whole?"

Charles Whiting Baker brought out the point of the reaction upon the wage earner through the increased cost of living of the

[1] See the December Journal, p. 1035, for abstract of paper.

[2] Care of C. E. Knoeppel & Co., 101 Park Ave., New York City.

inflation of wages. He was followed by Hugo Diemer, who emphasized the same thought, saying that the understanding of these economic principles presupposed education of the worker, of the engineer and of the general public. He spoke then of a course in Industrial Engineering which for a number of years has been given at the Pennsylvania State College and in which it is attempted to bring out some of the human phases of engineering. His remarks were a defense of the teaching profession, and in answer to the general criticism that engineers lack training in these less mathematical and technical phases of their profession.

John Clinton Parker said that the non-financial incentive applied to himself was to build up something that would be a credit to him, and that this was an incentive which applied to every one. He was also impressed with the fact that the solution of the problem of labor was endangered by a lack of faith and a false notion of elementary economic principles.

Frank B. Gilbreth spoke of the changed conditions which were confronting industry with the close of the war. Where a soldier was returning to his former job, now held by someone whom he considered his inferior, he found that more work had been accomplished than he had been accustomed to do and that greater productive effort was to be required of him in the future. So true was this in Europe that it has resulted in the eliminations of all restrictions upon output. The realization has come that the salvation of the world lies in big outputs per man. Engineers and economists have known this for some time, but laborers have not. They have held an honest belief that restricted output was the one thing which assured every man his job. They are not going to believe this any more because the labor leader knows that it is not true. Further, the laborer will not only release all limitations upon output but he will use his craft and skill to increase output. The workingman's committee is operating in a number of places as yet unannounced and with remarkable results. They are not interfering with the management in obtaining intensive outputs but are working on such things as heating and ventilating, elimination of labor turnover, the selection of the right man for the right place, fatigue elimination, education and corporation schools.

Arthur C. Jackson drew attention to the law that investment is entitled to an income. The investment may be in the form of cash, of invention, of accumulated earnings or of the results of the continued services of an employee. There should be a standard way of measuring all of these investments, and it is the duty of the engineer to solve the problem of the fair division of the profits resulting from these investments. Wealth is not alone dependent upon money but in the end upon production. This country must continue to be an exporting country if it is to maintain its position in the countries of the world. We can only maintain a wage scale above that of our competitors by the proportion that our production exceeds the production of our competitors.

Arthur L. Williston expressed the fear that the interest stimulated in an employee by teaching him how to perform his job properly would begin to lag after the attainment of the desired degree of perfection became an old story. He considered that the employer should have a new and greater lesson to teach as the simpler ones were mastered, looking upon his workmen as progressing from stage to stage in his industry as a student progresses in college from one class to another.

In his closure Mr. Wolf said that in his plants there was no difference between capital and labor. They were all fellow-workmen. He explained how he secured the spirit of coöperation with his employees by appealing to their intelligence and sense of justice, adjusting their wages by conferences, etc. He said that the men were promoted throughout the plant in much the same way as men progress through an educational institution. He contended that there was never trouble to be had with labor if the employer went to labor in a frank spirit of open coöperation. He thought that labor leaders realize that the workman must stop focusing his attention upon the distribution of wealth and focus it upon the production of wealth, after which the compensation would surely come.

In reply to some questions from Spencer Miller, who thought that the speaker might have contradicted himself in saying that men were rewarded by promotion and also that the incentives were non-financial, Mr. Wolf once more made the point that men do not do their best work for money. "It is the record, it is the accomplishment of the man that counts, and it is fundamentally self-expression that the man wants." The financial reward is bound to follow, and the employer who gives a man a chance to use his brain power and does not give him the financial compensation that goes with it is doomed to failure.

In answer to a question as to the disposition of the saving due to the improved efforts of employees, Mr. Wolf was of the opinion that the money should be divided, that the men should be part owners of the industries. It has been because workers have not worked intelligently that employers have been able to deprive them of this division of profit. The employer has used his brain to exploit the employee; the employee first used his brain to organize against the employer. That employee must be induced to use his brain for productive work. Then he will realize, as his mental capacity increases, that his reward is bound to follow.

Accused good-naturedly by John Clinton Parker of being a labor leader, Mr. Wolf replied that all engineers were labor leaders in the big sense of the word. Some one had said that the labor problem must be worked from within outward. The point of view cannot be imposed upon the laboring man. "The greatest potential force that exists in this country today for constructive leadership and disciplining of the destructive elements is organized labor. . . . Because there is a certain esprit de corps among them, so that, if you can get them harnessed into the partnership in a constructive way, get them focused upon the production of things, the power is tremendous."

Spencer Miller delivered a vigorous and inspiring address appreciative of the awakening which had come with the war and which had been the spirit of the papers of the day, and ended by proposing a vote of thanks from the Society to Mr. Wolf.

Robert L. Sackett amplified the remarks previously made by Hugo Diemer with reference to the courses in industrial engineering at the Pennsylvania State College, and was followed by Prof. A. G. Christie who, in the absence of Charles Piez, read his paper entitled The Evolution of the Organization of the U. S. Shipping Board, Emergency Fleet Corporation, which appears later in this report.

Discussion of Paper on Employment of Labor, by Dudley R. Kennedy [1]

In presenting his paper, Employment of Labor, Dudley R. Kennedy [2] said that he had been in the business of employing labor for eight years, and was considerably impressed to hear such a discussion of the subject of human engineering as had taken place that day. He wondered if, in the newly awakened interest in human engineering we were not turning to the frills in a sudden desire to conquer the problem. Collective bargaining to him did not mean dealing with a labor union or the one labor union of this country, but dealing with the people of his factory collectively. He could not agree with many economists with regard to the cost of living, but felt that the raising of wages in and of itself continually raised the cost of living, and the man with a short pay envelope never quite caught up. He insisted that if industrial relations were to be studied in a plant, the man to do it should be the best man money could procure, and not some clerk who had read a book on management. It required the best brains available.

L. W. Wallace, discussing the paper, emphasized this same point. Robert G. Wells was equally certain of it. He said the problem of getting labor and of maintaining an adequate and efficient force was just as large as any other industrial problem and was deserving of a department reporting directly to the head of the organization. He hoped the day would come when we would cease to use the terms "labor" and "capital."

[1] See December Journal, p. 1030, for abstract of paper.
[2] American Internat'l Shipbuilding Corp'n, Hog Island, Philadelphia, Pa.

Just as business men had found that their competitors were their best friends, so labor and capital should regard one another and coöperate.

Intensive Training by the Committee on Education and Special Training

Mr. C. R. Dooley[1] then read his paper on Intensive Training. The Committee on Education and Special Training was appointed to train drafted men as specialists in required trades. The program outlined by the Committee and the methods followed by them in carrying out their work were briefly described in this paper.

It was considered that the first essential step in educating the men was to accustom them to military obedience and discipline. Their classification was not based completely upon their past experience, but consideration was also given to their latent native abilities. Lastly, and the most important, the program of the Committee called for stimulating and fostering the qualities of originality and initiative. It was pointed out that the Committee was still capable of doing valuable work in training the returned soldier for industrial work during the process of demobilization.

James W. Russell,[2] in a written discussion, spoke of the work which had been done in the intensive training of boys and women at the plant of the Curtiss Aeroplane and Motor Corporation. A balcony was cleared and at least one machine tool of the same general character as those used in the shop set up for the "school." After a few weeks' training the pupil was sent to the shop. It was found that every person who entered for training was fitted for some one of the various divisions in the school, change within the school being a simple matter when the adaptabilities had been studied. In six months, 1500 employees were promoted to various departments of the plant. It was found that the selection of the instructor had to be done carefully, as it was necessary that he have not only a good character and a skilled knowledge of his trade, but also an ability to instruct.

In a written discussion, H. E. Miles[3] said that usually the powers of the individual man drawn upon did not exceed forty or sixty per cent of his possibilities, leaving a great reservoir untapped. The war had taught us to utilize this. It had taught us to train in six weeks where years were needed formerly in the wasteful apprentice system. He believed that the value of the practice of intensive training taught by the war has been proven in many factories and was about to be accepted as a part of the essential production program of every first-rate shop.

A. A. Potter wrote: "The work of the War Department Committee on Education and Special Training will result in the establishment of intensive short courses at many of our colleges and universities for the purpose of training industrial workers, who for lack of time on account of insufficient means are unable to devote more than a few months in preparing themselves for their life work."

He felt that the following factors contributed to the success of the Committee's scheme:

1 The men were prepared for a definite need

2 The courses were carefully supervised and the stress had been laid on the necessity of teaching men and not subjects, upon the desirability of building up a man's experience and ability

3 The men were taught by doing. The concrete preceded the abstract and the student saw the practicability of such instruction.

For work of this character to be successful in peace times, an industrial incentive must be developed to take the place of the war incentive. This can best be accomplished if the various industries tell the educational institutions their needs and allow the institutions to train men for a definite job.

A. B. Segur[1] mentioned in a written communication the work of Frank Gilbreth at Fort Sill in studying the motions of infantry and artillery for the instruction of officers in conducting themselves in the field. He said the Red Cross Institute for the Blind was availing itself of intensive methods of education in its work of fitting blinded men for well-paid positions in the industries.

Arthur A. Reimer, discussing the paper orally, said that what Mr. Dooley had done with the training of the army showed the possibilities latent in our nation—possibilities to be developed by our engineers.

Arthur L. Williston was impressed with the fact that what Mr. Dooley had been doing was the basic purpose of scientific management: to determine the right process, to select the right man, to educate the man to do the job in the right way and to create in that man the maximum incentive. All the way through the discussion of management too much emphasis had been placed upon the right process and too little on the selecting of the right man, the training of that man, and the creation of the incentive.

In the absence of F. A. Waldron, his paper, Labor Dilution as a National Necessity,[2] was read by title, and the reading of a written discussion by Charles E. Fouhy[3] omitted because of the lateness of the hour.

THE ENGINEER IN FOREIGN SERVICE

By HON. L. S. ROWE,[4] WASHINGTON, D. C.

I HAVE come to you to take counsel at this critical period in our nation's history with reference to a national and international service which you, the engineers of the country, are in a position to perform. The winning of this war carries with it heavy responsibilities, especially for the United States. Our entry into the conflict has been free from all selfish purposes and has been prompted by a spirit of service to humanity. It is for you and for me, as citizens of this country, to see to it, in our respective fields of activity, that these high standards and that these high purposes shall not remain empty words. The engineering profession can boast of a splendid record of achievement. My plea is rather for the broadening of this spirit of service in order that a larger proportion of your profession shall be equipped to serve in foreign lands and particularly our sister republics of America, in the great engineering problems which confront them.

These problems have a deep significance for the future of America. Upon their solution depends to a very considerable extent the degree to which large sections of the American continent shall be made habitable, and beyond this, the extent to which the republics of Central and South America shall fulfill the great possibilities which are before them. It is not merely a question of the development of the natural resources of these countries and their consequent increase in wealth. Larger social purposes are also involved, for with the development of these resources the condition of their laboring population will be materially improved. It is a notable and significant fact that each great engineering work in Latin America has brought with it a rise in the standard of life of considerable sections of the population.

I have seen American engineers at work in almost every part of the American continent, and I have been impressed not only by their technical preparation and ability, but by the broad statesmanship that they have shown in the handling of large masses of foreigners and in their dealings with foreign governments. But the number available for the work has been entirely too small, and I am firmly convinced that in order that the United States may constantly have an engineering reserve to meet the needs of this continent, it will be necessary to broaden the training of the engineer in order that he may set forth with something more than the technical equipment of his profession.

The opportunities presented to the engineer in the countries of Latin America, both pecuniary and from the standpoint of

[4] Assistant Secretary of the Treasury.

recognition, are so great and so varied that all that it will be necessary to do will be so to adjust the preliminary training and equipment of students of engineering that they will be prepared to avail themselves of these opportunities. In order to do this it is indispensable that a larger percentage of our engineers leave the engineering schools with an adequate knowledge of the Spanish language. This is the first and an indispensable requisite. There should also be instruction in Latin-American political institutions in order that the engineer may know something of the system of government in the country with which he is to be associated. But beyond these questions of technical equipment we must instil into the mind of every engineer the larger international service which he is rendering when he undertakes a great work in a foreign country, especially if such work is undertaken for the government of the country. This means a greater breadth of view combined with a certain cosmopolitanism which will assure ready adaptability to new conditions and to new requirements.

During repeated and extended tours through South America I have time and again been asked to assist in securing the services of irrigation engineers, electrical engineers, engineers for the designing and erection of public works and other important public enterprises. There has been no difficulty in finding men equipped to do such work, but there has been a very real difficulty in finding American engineers prepared to expatriate themselves for a period of years in order to undertake such work and to carry it to successful conclusion. In spite of our cosmopolitan make-up there is a lack of adaptability of the average American in adjusting himself to foreign conditions, which makes it exceedingly difficult to secure men who are willing not only to begin, but to complete large public works in foreign countries. This has been true not only in engineering, but in every other field of endeavor. American commission houses in South America must engage Swiss, Dutch and even Germans because of the unwillingness of American employees to settle down in those countries for any lengthy period. Almost every American that I have met serving in a foreign country feels that he is making a great sacrifice in consenting to expatriating himself even for a relatively short time. At the end of about six months he begins to show signs of impatience and at the end of a year his homesickness reaches a point which at times leads him to leave his work incomplete. Furthermore, there is too often a failure on his part to place himself in touch with the people of the community in which he is living and he thereby fails to exert the broader influence which would be of such great value to his country.

This defect has been less marked in the engineering profession than in any other. What we need first of all is a clear conception of the very real international importance of service in foreign countries. I am convinced that if the entire engineering profession were to realize the extent to which its members can serve in promoting the spirit of international coöperation which the President has placed before us in such eloquent terms, greater effort would be made in preparing and encouraging members in that profession to respond to the call, especially when such calls are made by our sister republics of this continent.

It is important, however, to bear in mind that whenever a member of your profession undertakes the supervision of a public work in a foreign country, he becomes in a very real sense a representative of the people of the United States. He must be able to understand the viewpoint of nations different from our own in historical and ethnic make-up. The engineer in charge of great public works has often under his immediate direction great masses of native labor and it is most important that he should show a real interest in their welfare, contributing within the measure of his power toward the increase of their efficiency and the raising of their standard of life. In a hundred different ways the members of your profession can make themselves factors of very real importance in the progress of the countries which they are called upon to serve and at the same time become to the people among whom they are called upon to labor the interpreters of the best in our American life. The responsibility is a heavy one, but the magnitude of the results is commensurate with the responsibility.

ORGANIZATION OF THE U. S. SHIPPING BOARD EMERGENCY FLEET CORPORATION

By CHARLES PIEZ,[1] PHILADELPHIA, PA.

The United States Shipping Board was created by Act of Congress, approved September 7, 1916, "for the purpose of encouraging, developing and creating a naval auxiliary and naval reserve and a merchant marine to meet the requirements of the commerce of the United States, with its Territories and possessions, and with foreign countries; to regulate carriers by water engaged in the foreign and interstate commerce of the United States; and for other purposes." The Shipping Board, under the provisions of this Act, was given the power, if in its judgment such action was necessary, to carry out the purposes of the Act, to form under the laws of the District of Columbia, *one* or *more* corporations for the purchase, construction, equipment, lease, charter, maintenance and operation of merchant vessels in the commerce of the United States, and in the exercise of the power so granted the United States Shipping Board Emergency Fleet Corporation was organized on the 16th day of April, 1917, with a capital stock of $50,000,000, all of which has been subscribed for by the United States Shipping Board on behalf of the United States. As the Shipping Board is, under the Act, charged with the responsibility of doing all things necessary to protect the interest of the United States in the Emergency Fleet Corporation, it has elected to place the control of the Corporation in the hands of a Board of seven Trustees, five of these Trustees being the five Commissioners composing the United States Shipping Board.

It is evident that by this method of control the vast responsibilities which the war has created rest in the final analysis upon the five Commissioners of the United States Shipping Board. And when it is remembered that these gentlemen have been confronted with the task of blazing new trails and establishing the fundamental policies in connection with the giant tasks of regulation, construction and operation, the troubles which made the early days of the Shipping Board a byword find ready explanation. Relief from this over-centralization of responsibility and control could, of course, be secured through the exercise of these three main functions by three separate but related and centrally controlled bodies, and the Act itself provides for just such a solution.

When Mr. Hurley took office, the by-laws of the Fleet Corporation provided that the officers were to be a President, a Vice-President, a Treasurer, a Secretary, a General Manager, and such other officers as the Trustees might determine. They further provided that the General Manager should have the general oversight and management of the business and affairs of the Corporation, and should have power to employ and discharge all clerks, employees and agents, determine their salaries, and prescribe and define their duties. In other words, the titular head of the Corporation was assigned merely nominal powers, and the General Manager, who is usually an appointed officer, was given full executive control and responsibility, but yet lacked the power to complete contracts, a most important and necessary function for speedy prosecution of the work in those early days of pressure and stress.

The Denman-Goethals controversy arose quite naturally out of this faulty scheme of organization. Mr. Hurley improved this condition tremendously when late in November the by-laws were amended so that complete power was concentrated in the President of the Corporation, with the authority to delegate it, and the General Managership was made an appointive instead of an elective office. But, in spite of this wise and necessary step, the process of decentralization above outlined would have improved the administration of both the constructing and the operating division and would have relieved mightily the pressure on a much overloaded Board.

The relationship and functions of the United States Shipping

[1] Vice-President and General Manager, U. S. Shipping Board Emergency Fleet Corporation.

Board and the two divisions of the Fleet Corporation are shown in Fig. 1.

In the popular mind the Construction Division is considered the Emergency Fleet Corporation, and as it is to the Organization of this division that this article will address itself, I will follow the popular misconception and refer to this division as the Fleet Corporation.

The Corporation began in reality as a designing and contracting organization, and for the first four months of its existence these two functions overshadowed all others. On August 3, 1917, however, all vessels in American yards, under construction or contract for either domestic or foreign account, were requisitioned, and this step brought with it the control of the construction of 413 vessels, necessitating the addition of a division of construction to the skeleton organization then existing.

But the country's needs for ships could not be satisfied with the output of the shipyards then existing, and substantially every one of the earlier contracts for vessel construction carried with it the obligation of constructing wholly new facilities. Designing vessels and contracting for their construction, which constituted the first phase of the Corporation's work, was quite naturally followed by plant and shipyard construction as the second phase. In the meantime, however, the demand for war supplies was making heavy inroads not only on the available stocks, but on the producing capacity of the industries as well, and the Emergency Fleet Corporation found itself compelled to assume increasing responsibility for furnishing all of the new yards, and many of the old ones, with the necessary raw and finished material.

In the construction of wood steamers, only a few yards, for instance, accepted contracts for the delivery of complete ships, the remaining yards undertook the construction of wood hulls only, for which the Fleet Corporation had to provide not only the lumber and fastenings, but the chains, anchors and other hull accessories as well. The Corporation had to furnish in addition the boilers, piping, engines, propelling machinery, deck machinery and all other parts of the equipment, and had to construct separate plants at which this machinery and equipment could be installed on the hulls delivered by the hull contractors.

As the construction program developed it became evident that the two main problems confronting the Corporation consisted in securing an adequate supply of labor and an adequate supply of material delivered in proper sequence. On August 1, 1917, the number of men engaged in the shipyards was in the neighborhood of fifty thousand, and that number, under the drive of our great necessity, was increased sevenfold in almost as many months. The men were brought to the shipyards by patriotic appeals, by the lure of high wages and by the probability of exemption from the draft. The problems connected with securing and building up this huge army of workers were numerous and complicated, and justified the creation of the Industrial Relations Division, with its various sections. The Division of Industrial Relations became charged not only with responsibility connected with the labor supply, its proper maintenance in health and safety, and the adjustment of minor differences and delinquencies; but it had to accept the burden of occupational draft deferments, the training and stimulation of workers, the proper allocation of the available labor supply, including the elimination of "scamping," and last, but by all odds the most difficult, the control of a proper adherence to the day rates, piece rates and classification of occupations established by the Shipbuilding Labor Adjustment Board.

But the establishment of a stable and effective labor force at each of the yards involved another problem of considerable magnitude. Unfortunately, the shipyards clustered about the fringes of the highly congested industrial centers of the seaboard and on the Great Lakes, and almost everywhere there were lacking adequate transportation facilities, adequate housing facilities, or both. Ninety-five million dollars were appropriated by Congress to relieve these conditions in the shipyards alone, and the Division of Passenger Transportation and Housing had to be developed in record time to assume charge of this highly important piece of emergency construction.

Securing an adequate supply of material in proper sequence, presented in essence just as many and as serious a set of difficulties as did the supply of labor. Beginning with the simple act of purchasing, the failure to make deliveries called very promptly for the organization of a production and expediting department, and the necessity of bringing the finished material to the completed hull presented a most interesting and difficult task in allocation, dispatching and transportation. It must be borne in mind that the Fleet Corporation accepted substantially full responsibility for supplying the raw materials, the finished materials, and the machinery for a wood ship program amounting to $450,000,000, and that, in addition, it was charged with the burden of securing all of the steel and a large part of the machinery for a steel ship program at least six times that size. Purchasing was but a minor part of a problem that involved responsibility for delay in supplying material of every character to every one of the 171 yards under contract with the Corporation.

It was considered best to concentrate in the hands of a single division the responsibility for buying, and delivering to the yards

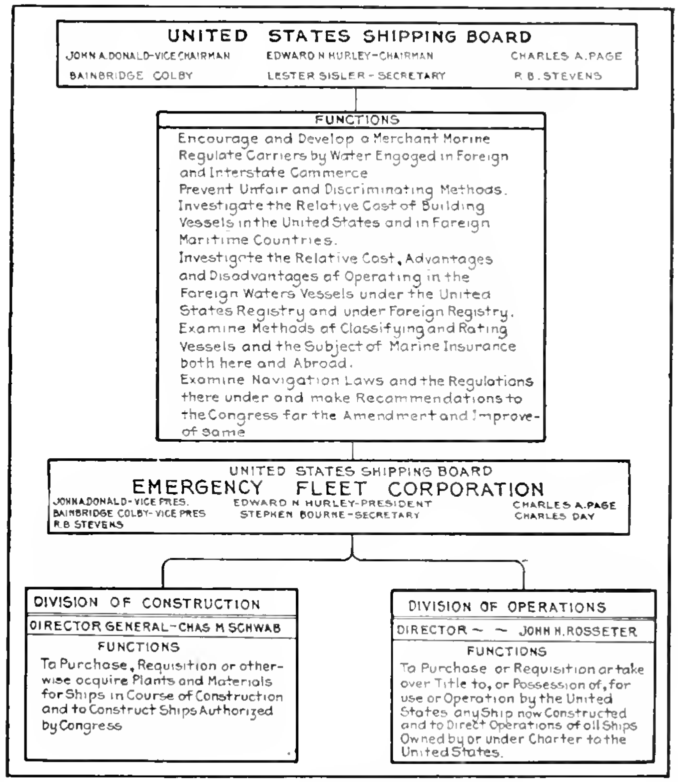

Fig. 1 Relationship and Functions of the U. S. Shipping Board and the Two Divisions of the Fleet Corporation

on time and in proper sequence, all the material the Corporation was charged with furnishing, and the functions of purchasing, of tracing and expediting, of allocating and dispatching, of inspecting and of transporting, which in the earlier days of our development were performed by three different departments, were thereupon consolidated under the control of the Supply Division. This division built up effective district organizations in the various industrial centers of the country and maintained its contact with the shipyards through representatives in the offices of the District Managers in the shipbuilding districts.

There were then, in reality, two great supply divisions, one undertaking to provide the necessary labor and the other the necessary material, and these two divisions served the four divisions that were charged with the supervision of construction: The Division of Housing and Transportation, the Division of Shipyard Plants, the Division of Steel Ship Construction and the Division of Wood Ship Construction. Each of these divisions developed its own technical department, excepting that in the case of the two-ship construction divisions a single technical department covering both naval architecture and marine engineering, for both steel and wood ships, was created and placed under the administration of the Division of Steel Ship Construction.

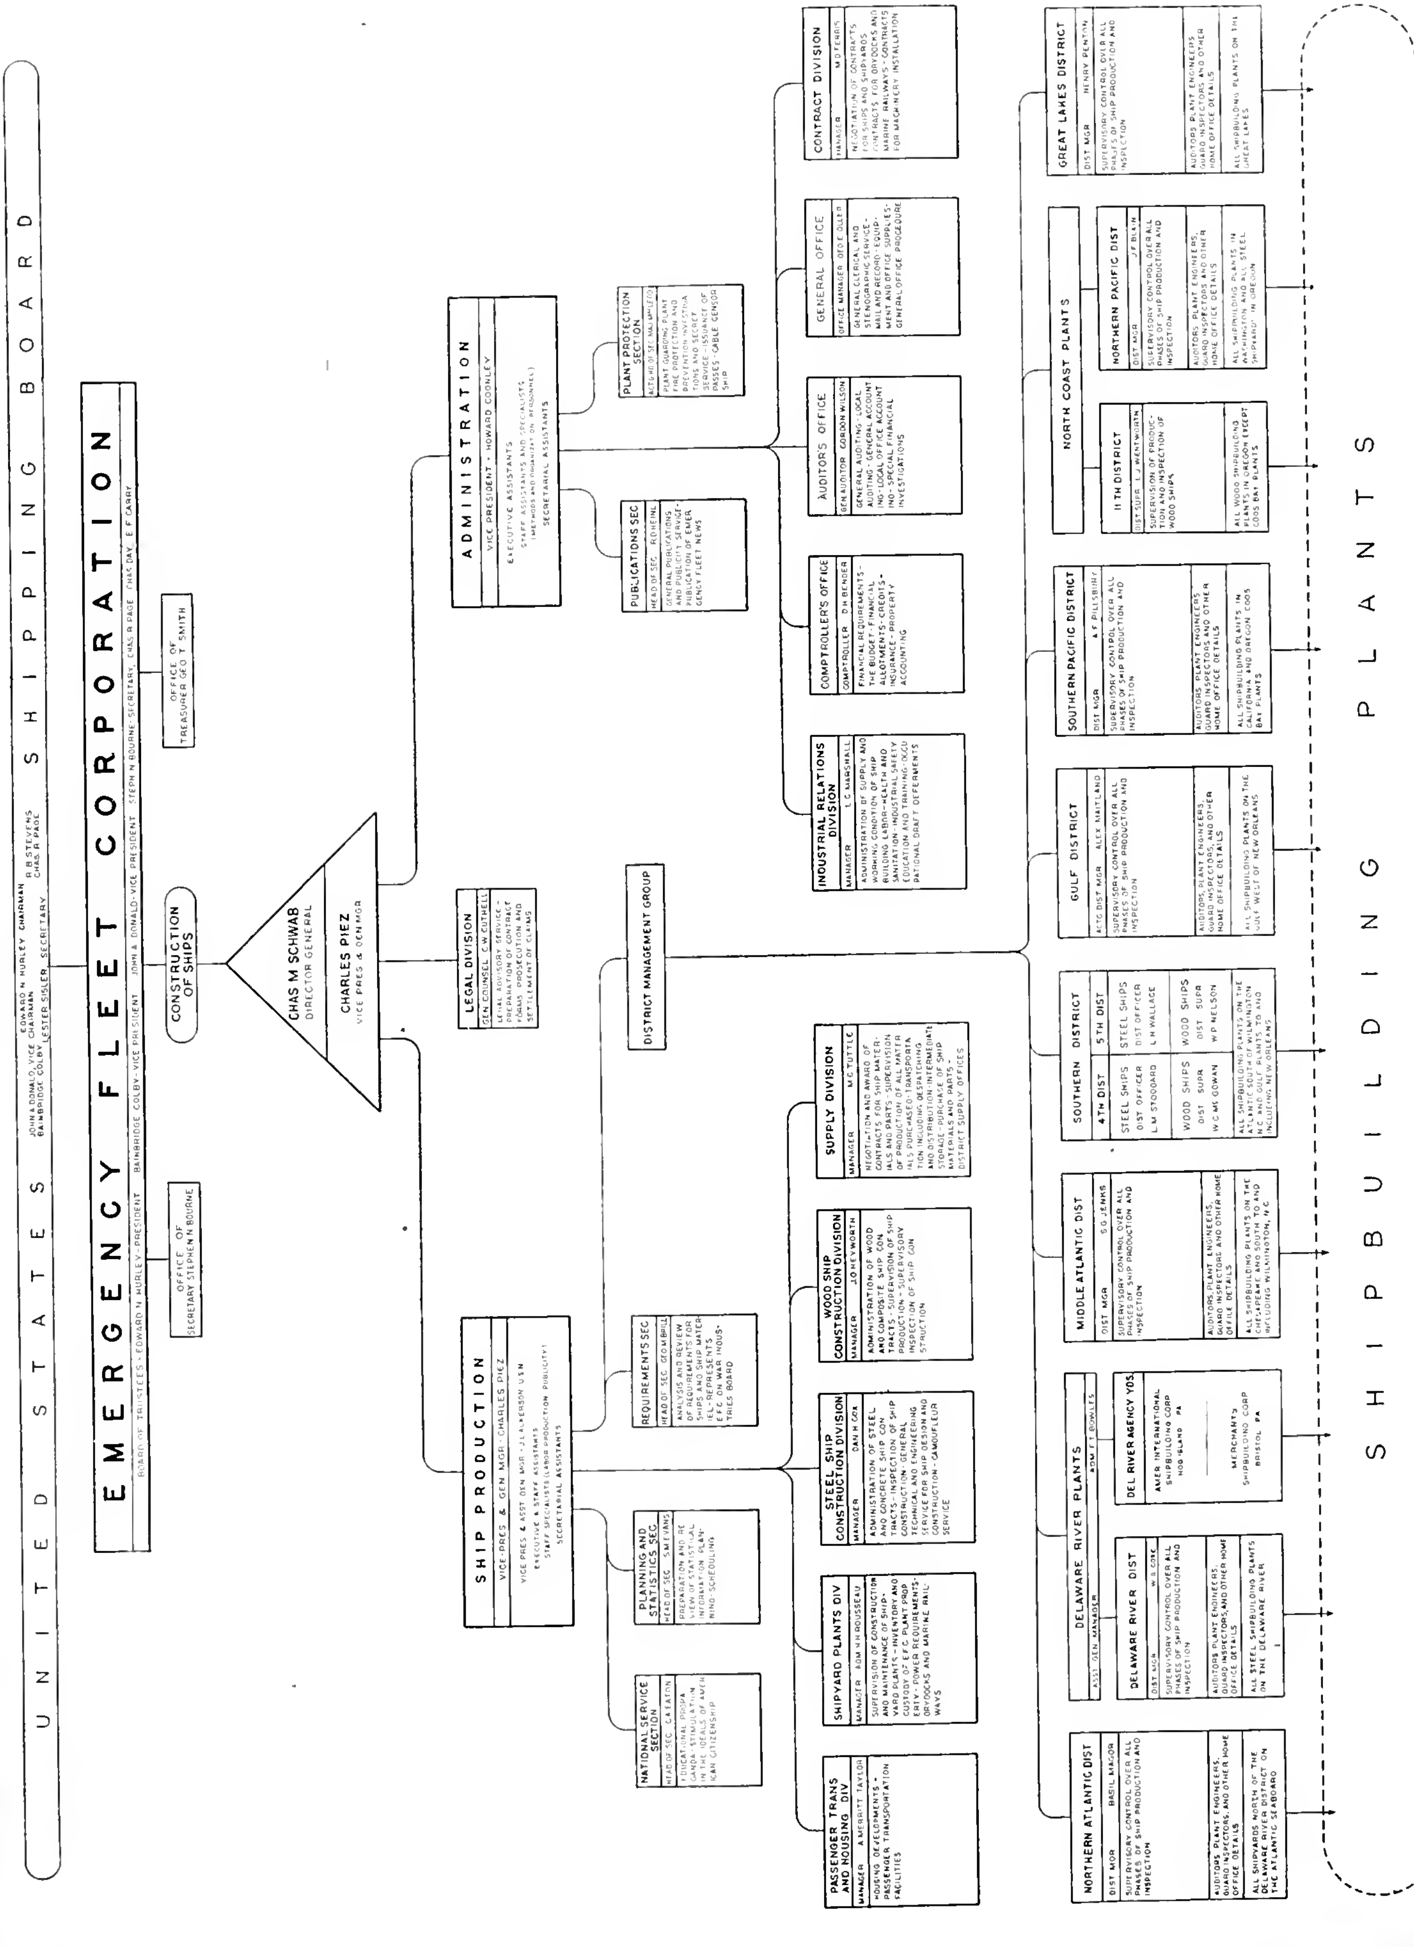

Fig. 2 Chart Showing Organization of the Emergency Fleet Corporation

For the purpose of controlling the actual construction in the field, the country was originally divided into eleven districts, in each of which there was one or more representatives of each of the construction and service divisions and sections. Later the control of all of the functions in each district was placed in the hands of a district manager who, as the direct representative of the Vice-President and General Manager, exercised in respect of the districts all of the authority which the latter exercised over the operations of the Corporation as a whole. The number of the districts was also reduced from eleven to eight.

This step of decentralization aided materially in the expedition and dispatch of affairs, particularly as the lines of direct communication between the sub-heads of the district and the corresponding division heads at the Home Office were preserved.

The various divisions and sections at the Home Office communicate directly with their appointed representatives, but send carbon copies of all directions and instructions to the District Manager, who is given the power to veto any instructions and stop any processes which, in his judgment, and from his local viewpoint and his first-hand contact with the problems affected, are inimical to the interests of the Fleet Corporation. Failing to convince the division or section at the Home Office of the soundness of his decision, appeal lies to the Vice-President and General Manager.

Time is a most essential factor in the development of any organization, and this is particularly true of those huge organizations that grew out of the necessities of the war. It took time to see and grasp the real needs; time to develop the scheme of the organization; time to pick and test the men to manage affairs; time to develop the proper team spirit, the spirit of discipline and submission to the central controlling authority.

Every division of the Fleet Corporation presented problems exceeding in number and magnitude the problems presented by an industrial or commercial enterprise doing a business of many millions a year, and every division required an organization of which the organization of the Corporation was but the pattern. The real difficulty lay not in choosing the general form of the organization as presented by the chart, Fig. 2, but in finding men who had not only the necessary experience and capacity for the job, but the proper temperament to blend quickly and harmoniously with the rest for the smooth and effective accomplishment of the task. Since the selection of the men presented the chief difficulty, we had no hesitancy in building our organization around the mental capacities and the temperamental peculiarities of the men we had available. The chart presented in Fig. 2 should not therefore be studied with the idea that it represents the last word in theoretical relationship and perfection. I have never been impressed with the value of a system chart unless I knew the men whose functions it depicted, for a chart without the personnel is like an equation with none but unknown quantities. The organization of the Fleet Corporation has been in a state of flux from the very first, and intentionally so, because it gave an opportunity for those quick changes and rearrangements which emergency conditions constantly demand. Today, with the pressure over, some of the functions will disappear, others will be consolidated and a new management adjusted to normal conditions will result.

The organization through the past six months of its career has been subjected to the constant critical study of an organization and methods section, attached to the staff of the vice-president in charge of administration, and this section has suggested administrative changes, has assisted in the definition of duties and responsibilities of the operating units, and has pointed out duplications of work and inconsistencies and overlaps in jurisdiction. It has made a study of the duties and responsibilities of different positions, and has developed a plan for bringing about uniformity in classification and salaries of employees, which is now in operation. Instructions given by the general officers of the Corporation are issued in the form of orders, which may be either general, special or technical; and these for the purpose of securing consistency and harmony with orders of a similar character previously issued are cleared through the Organization and Methods Section. The necessity of such a constant critical study of an organization which extraordinary pressure is expanding with great speed is apparent, and its value in reducing such a hastily gathered organization to a well-balanced effective unit is open to no doubt.

Coming now to a more detailed description of the organization as it existed before the signing of the armistice, complete power was delegated by the Board of Trustees to the Director General, who retained control of the policy of the Corporation, but placed control of the management in the hands of the Vice-President and General Manager. As an immediate relief to this official, the general duties and activities were divided into two main groups, one covering ship production, administered by the Vice-President and General Manager, with a Vice-President and Assistant General Manager in more immediate charge, and the other covering Administration, with a Vice-President in charge. The various sections and divisions, with their relationship and lines of authority, are so clearly indicated by the chart as to require no further comment, except that the position of the Industrial Relations Division, under the Administration group of activities, is due to a desire to more nearly balance the work of the two groups. The Industrial Relations Division serves the Production Divisions, but the relationship between the Vice-Presidents is so close and harmonious that the rather strained position of this division has resulted in neither embarrassment nor friction.

The Corporation is charged with responsibilities that involve a total expenditure of $3,880,000,000, and the construction of a fleet of vessels which, with certain emergency exceptions, will be so varied and well-balanced as to meet the requirements of our commerce with our own territories and possessions, and with foreign countries as well. The activities of the Corporation will result in an American Merchant Marine of 15,000,000 dead-weight tons, and the members of the organization who have spent many months under the high pressure of national needs look to that result for their compensation.

STANDARDIZATION AND ADMINISTRATION OF WAGES

By H. P. KENDALL,[1] NORWOOD, MASS., AND F. D. HOWARD,[2] WASHINGTON, D. C.

When the United States entered the war there was very little administrative machinery for dealing with industrial relations. These relations were affected in some slight degree by legislation touching hours of work for women, workmen's compensation acts, and other laws for the protection of workers. There was also the Department of Labor, which had very little or no authority to regulate industrial relations, but whose function was confined to publication of information and mediation of difficulties when called upon by both parties. Industrial relations were adjusted by the free competition between the employer and employee. The terms of the contract were determined by competitive industrial conditions, the relative demand and supply of labor, and the extent to which workers were organized for collective bargaining. These contractual industrial relations were largely determined by the relative bargaining strength of two parties and varied as the conditions of economic strength varied.

The system of contractual relations was in many cases modified by the benevolence or feelings of conscientious responsibility on the part of the employer on one side and by the feelings of loyalty and of ignorance of business principles on the part of the employees. These modifications were more likely to be present when the personal relations between employer and employee in small establishments were close enough to make personal relationship possible. In the larger establishments, where there could be no personal acquaintance and contact, the relationship was of necessity less influenced by other than economic considerations. Very general attempts had been made to evade this difficulty by the establishment of service departments in larger businesses, but this institutionalized benevolence outside the contract of employ-

[1] Treasurer, The Plimpton Press. Mem.Am.Soc.M.E.
[2] Executive Secretary, Committee on Industrial Relations.

ment was not always successful in eliminating the conflict of interests involved in the system of contractual relations.

The adjustment of relations by contract, especially during war times, involves difficulties too dangerous and wasteful to be tolerated. When there are swift and sudden changes in the relative supply and demand for labor the natural economic tendencies toward a new equilibrium of wages create unsettlement and unrest. It is a fundamental principle that there can be no free contract unless either party is at liberty to withhold a commodity or service for which he is bargaining. The withholding of the service of labor involves, unfortunately, the cessation of industry and is attended by waste and harm to parties not directly involved in the negotiations. Much of what is called industrial unrest is merely the natural manifestations of the bargaining process which is the fundamental part of the system.

Because the contractual relations are determined by the relative economic strength of the parties and because economic strength is created by organization, it is inevitable that the contracting parties should organize in order to secure an advantageous position by collective action for bargaining. The weakness of collective bargaining lies in the fact that it involves creating force, which may easily be abused or used for evil ends by unscrupulous men who are able to possess it.

War Labor Policies Board

The so-called labor problem was unquestionably the greatest political and economic problem of the American people prior to the war. The changes in production by machinery and the need for greater production with the coming of the war accentuated this problem and the extravagant and disproportionate wage increases have added to the unrest. The winning of the war depended on a new method of securing industrial peace so necessary to secure the required production. The War Labor Policies Board was created for that purpose, to work out a national policy and correlate the activities of the various wage-adjustment boards which were emergency instruments. The War Labor Policies Board made use of determined standards and adjudicated decisions which had met with the greatest success in both private industrial plants and in industries at large. Learning also from the British experience, it first set out to establish in one industry after the other, beginning with the most important ones from the war viewpoint, wage-adjustment boards more or less supervised by the Government agencies.

With the approach of peace, the winning of the war is no longer the supreme Government purpose, and with the close of hostilities the problem of industrial relations and industrial peace is relatively not less important, but more. It is by far the greatest problem that we face. The employing and the employed now have the opportunity to develop constructively a plan and policy for setting up standards and settling labor differences without the use of force. If industrial managers lead in this there will be no occasion for governmental interference or control. It is for us to determine the establishment of broad basic principles governing the standards and administration of wages. Such a subject, however, is far broader than mere wages. It means the entire field of industrial relations, of which wages is an important part, not the whole factor.

In order that the productive energies of the nation might not be dissipated in wasteful labor controversies, it became the first duty of the Government to provide activities to secure industrial peace. A sudden change in the condition of supply and demand brought into play tendencies to unsettle the accustomed status of wages, hours and conditions of work. This was accentuated by the same tendencies operating to change prices of commodities as manifested in the increased cost of living.

The time was too short to deal with the problem fundamentally. For the settlement of controversies the Government organized the War Labor Board, properly known as the Taft-Walsh Board, whose function it was to adjudicate disputes. In order to secure some measure of consistency in their decisions, the Board recommended a set of principles which was prescribed by its president. The principal points were the recognition of the right of the worker to organize to bargain collectively without fear of the customary measures of employers to prevent this, the living wage and the 8-hour day.

In addition, a coördinating agency was established, known as the War Labor Policy Board, composed of representatives of the purchasing departments of the Government. The functions of this board were to create uniform standards in industrial relations and uniform policies for their administration.

Post-War Labor Problems

With the end of the war, the greatest industrial problem doubtless is this: What general principles shall be followed in dealing with the labor problems of the future with all their unseen dangers and possibilities? War has changed conditions to such an extent that a return to the *status quo ante* is difficult, even though it were desirable and possible. The only alternative to the old system of allowing industrial relations to be adjusted by natural economic laws and preventing bargains seems to be that of standardization, or the conscientious and systematic regulation of these relationships by collective action, which does not necessarily mean Government administration, but which may be accomplished by voluntary collective action.

The term "standardization" does not necessarily mean uniformity of wages, hours or conditions of work. It means the determination of these conditions according to general principles, the justice of which is universally acknowledged. It is much easier to establish general principles than it is to derive the particular standards and apply them to actual situations.

The regulation of industrial standards by joint boards as suggested has the great advantage over the present system in that it eliminates at least three-fourths of the cost of friction and strife between the particular employer and his employees. Each employer then adopts the standards which are current in his trade and knows that all his competitors are on the same basis and have no advantage over him. Even under our present system, the chief objection to any one employer's increasing wages lies in the fact that it comes out of the profits unless the increase is general among his competitors, when it is shifted to the consumer of the product. It is easy to foresee a time when the public and not the employers will have the chief interest in opposing wage advances.

In many, if not most, of the cases where employment conditions are admittedly unsatisfactory, the employers are helpless to improve them on account of the pressure of competition. The plan for organizing adjustment boards provides a remedy for this by attempting to establish standards for itself which are protected against demoralization by competition.

The tendencies for industries to become more and more dependent upon each other is increasing and the consequence of this is an increasing necessity for industrial peace. The indirect effects of stoppages increase with the greater integration of industry, and the number of interests and people who suffer from labor difficulty and yet have no direct participation in them grows each year. A street-railway strike, for example, in a great city causes a collateral loss of business all out of proportion to the amount in dispute between the company and its employees. The indirect interests affected by labor disputes are therefore becoming so important as to be entitled to more consideration than formerly.

The administration of industrial relations, especially wages, by a skilled person specialized for the work is no longer an experiment. No industrial administration is complete until in some part it is sensitive or responsive to the aspirations and grievances of the employee. The efficiency of production is often affected fundamentally by action taken in other departments of the business. Moreover, the labor manager has an opportunity to interpret a business policy to be established by the working force and may frequently forestall opposition and ill-feeling by timely explanation of the reasons for such policies and standards.

There is a tendency where standards are fixed by haphazard methods or in the heat of struggle with labor unions for certain fundamentally right and efficient principles to be overlooked or

submerged. That wherever there is a standardized wage there should also be a specified measure of proficient labor performed is not to be disputed by any reasonable person; yet situations are created where this just principle is opposed by labor organizations who feel compelled to take that position because of the circumstances of the situation. Another principle, equally self-evident, is that every worker has a moral right to compensation in direct proportion to his individual accomplishment, yet for reasons which seem to them to be valid, the unions frequently set themselves squarely against piece-work or bonus systems which aim to employ this principle. Under some system of standardization it is likely that these just principles may be reëstablished with proper safeguards against abuse.

Labor to Coöperate

The war period has created a very perceptible change in attitude on the part of employers toward what is loosely termed "collective bargaining." This means that employers recognize the need for a greater sense of responsibility on the part of the employees toward the efficiency and success of the business in which they are engaged, and that in order to develop this sense of responsibility greater participation shall be granted to the workers. Moreover, the worker should be given an opportunity to learn more about the policies of the establishment and the difficulties of management. It is recognized that the indifference and even hostility of the workers to efficiency arises from their relationship to the business and the absence of reasons why they should be interested.

The Federal Labor Administration, following the President's proclamation by which the War Labor Board was created and manifested in the collective-bargaining clauses of the Quartermaster's and Ordnance contracts, gave an impetus to the general principle of participation in management which many have begun to see offers an opportunity for a general betterment of industrial relations in individual plants. The introduction of a system of organized representation of employees by the Standard Oil interests and the apparent success of the idea has stimulated general interest, and it now appears that this idea is likely to be much more generally accepted, especially by large industrial plants. That responsibility creates conservatism is a truth which has been demonstrated, and nowhere more convincingly than in industrial relations. Give employees responsibility and opportunity to exercise it, and sooner or later there must develop leadership among them which will contribute not a little to the vitality and general efficiency of the establishment.

To make this plan truly successful, however, the management must decide to give labor a fair share of the results of the efficiencies and economies realized. Too often by the introduction of new methods and labor-saving machinery the employer cannot bring himself to yield a share of the benefits to the employees, although he expects them to bear uncomplainingly the hardships which may attend the transition. The difficulties of systematically giving to the workers their share of the profits are perplexing. The subject of profit sharing is very attractive, but the difficulties have frightened many away from the subject. Any system of profit sharing should take into full account the permanent needs of the worker and attempt to satisfy them to a maximum. It is difficult to know what is the right and just method to use, but the difficulty will be largely overcome in individual establishments by the proposed plan of standardization or regulation of industrial relations.

INTENSIVE TRAINING

By C. R. Dooley,[1] Washington, D. C.

The run of the draft only partially supplies the number of trade specialists needed by the army. At the Field Artillery Replacement Depot, Camp Taylor, the Personnel Officer is able to get just one-half the required specialists from the draft, and he looks to the Committee on Education and Special Training for the balance.

The records at the camps show that less than ten per cent of the men have had a high-school education or better and that the great majority have had no special training of high degree, and lack skill or even any continuity of experience.

The Committee on Education and Special Training was appointed in February 1918 with instructions to train men for the service. First of all the men must be soldiers, disciplined to prompt and complete obedience and broken into the routine of army life; second, they must be skilled in those trade specialties needed in the army; third, they must have that originality and initiative which will enable them as soldiers to use the tools and materials at hand in meeting emergencies.

The Committee adopted a program about as follows:

1 Military training
2 Sorting and training according to ability
3 Trade fundamentals and combinations
4 Development of originality and initiative.

Two months were allowed as the length of each course and six months, April 15 to November 15, were assigned to the experiment. A total of 90,000 men were to be trained.

Administration, Organization

The Committee and executive military officers remained in Washington in charge of the planning. The United States was divided into ten districts with field military officers and district vocational directors in full charge of administrative details. They literally went from coast to coast inspecting, approving and establishing units, wiring in the results each night from April to August.

A large production chart showed the capacity necessary to be arranged for each day in order to meet the 90,000 by November 15. The great majority of school heads were willing and eager to tackle the new job. No greater evidence of American resourcefulness has been developed than that of the 140 odd schools in their radical changes of equipment, methods and policies to meet this emergency. We all agreed it could not be done, but had to be, and that was sufficient. The production chart was eagerly watched day by day until the danger line was passed, and now we are closing up the experimental period with a total of approximately 100,000 men trained in some thirty different trades.

Methods Employed

Military Training. Three hours a day were devoted to Infantry Drill, Military Courtesy, Inspection, and General Military Training, tending not only to break in green men but to develop habits of promptness, precision, order, and to establish a company spirit in place of the normal American individual spirit.

Sorting and Training According to Ability. Both the experience and the natural aptitude of each man were used as a foundation to build upon. Where these coincide the job of training is easy. Where they are opposed the best of judgment and tact must be used to determine the right classification and assignment. If a man has made a success at a given line of work the chances are favorable for giving him further special training in the same lines. On the other hand, circumstances of youth have often prevented men from following their natural talents. Such cases are by no means the exception.

For example, the Dickinson High School of Jersey City positively had the least desirable detachment of men sent by the various draft boards to any school in the second district, and I am inclined to believe to any school in the country. Over 60 per cent came from the lower east side of New York: sweat-shop workers, garment workers, toughs, men from the docks, teamsters and every kind except men from the mechanical trades; men who had never been in an industrial shop; never handled a shop tool and who seemed hopeless for training.

They were assigned to classes and our job was started. In a few days there was a remarkable change. An able commanding officer and his lieutenants took them in hand. Due to this admirable military discipline and the efficient shop instruction some

[1] Educational Director, Vocational Instruction, Committee on Education and Special Training, War Department.

360 "fighting mechanics" were delivered to the army. Another group of laborers who had never done any forging were converted into capable blacksmiths within six weeks. In another case a young man who came directly from the farm was given instruction in sheet-metal work. In six weeks' time he was making stovepipe elbows of commercial quality from patterns which he himself developed by sound principles of descriptive geometry. In this particular school the instruction was given right in the machine shop in connection with the making of the pieces and the principles of projection and intersection were learned in a manner which made them a part of this young man's consciousness rather than by merely memorizing methods.

One of the inspiring things about these and hundreds of other incidences is the fact that the men themselves are enthusiastic about continuing with some form of industrial work even after the war. Three men in patternmaking at Carnegie Institute of Technology had formerly been bank clerks and declared most emphatically that they would never leave the woodworking industry.

The creative instinct seems to be fundamental in human nature and the accomplishment of practical results without help is the most stimulating of human experiences. With this motive established, a man normally becomes hungry for more accurate and deeper scientific information in order that his creation may be more perfect and he therefore begins to teach himself and the instructor merely becomes the means for the final checking of results.

That fundamental principles are infinitely more important than even a very great assortment of specific formulæ and rules is no longer doubted, yet this has been demonstrated again and again in the army training schools so that it will bear repetition here. For example, at one of the camps a group of soldiers built and installed a complete multiple-jack switchboard for telephone service out of nothing in the world but scrap. This could not possibly have been done without a thorough understanding of the simple principles of electricity and magnetism.

Many of the jobs in the army do not completely follow the standard lines of industrial occupation, and it was therefore necessary to define the duties of the men in terms of the work to be done, which many times included certain very definite combinations of parts of standard trades. For example, the operator of a mobile machine shop for the Ordnance Department must be able to operate a small lathe, a small drill press and do small vise and bench work. Further, he must be able to do gas welding, especially on thin metal parts, and must maintain in operating condition a gas-driven electric generator and several electric motors. Such an operator is called a machinist, although obviously a machinist as ordinarily known has no knowledge of gas welding or small motor operation, and could not fill the bill.

This emphasizes the great value of the man who can handle several different trades. Obviously he cannot become thoroughly skilled in all the phases of a number of trades, but by limiting the instruction to the fundamentals several allied trades may be covered, adding greatly to a man's usefulness.

Among other things that have been shown by the war to be advantageous is that type of efficiency which reckons on the personal originality of each man rather than on the completeness of the detail of his instructions, of a type of training that is flexible and elastic rather than rigid and exact in all predetermination. The war has been won through inspiring leadership that somehow seemed to spring from the atmosphere rather than through autocratic force. And so with the soldier-mechanic, much faith is placed in his ability to meet successfully new situations if only we can give him a correct understanding of the simple fundamentals of his trade and stimulate his constructive imagination.

The war is over. Thousands of men will return to industry with keen, alert minds, disciplined to act promptly and thoroughly as members of a team rather than as individuals. Many will not be highly skilled in civil occupations and will have to be trained in special work, but they will learn quickly and will advance rapidly because of their military experience.

The Committee on Education and Special Training could operate its organization backwards, so to speak, and train the returned soldiers for industrial work during the process of demobilization if such a plan were approved.

Industrial training means vocational skill, plus imagination and initiative, plus the discipline of keen service which marks the beginning of true leadership. It is hoped that the work of the Committee has contributed to the cause of general education in establishing some evidence of the fact that military training and vocational or academic training supplement each other; and in holding up before all students the motive of production for the community rather than for individual profit.

FIRST GENERAL SESSION

Discussion of Mr. Halsey's Paper on the Extent to Which the Metric System is Used in Latin America, and also Mr. Gantt's Paper Establishing a Relation Between Efficiency and Democracy

At the General Session, held on Thursday afternoon, Vice-President-elect John A. Stevens officiated as chairman. Two papers were presented, as follows:

The Weights and Measures of Latin America, Frederick A. Halsey

Efficiency and Democracy, H. L. Gantt.

Mr. Halsey's paper represents a thorough investigation to find out, from replies to about 500 questionnaires sent by disinterested American firms to prominent firms and individuals in the twenty-odd Latin-American countries, the system of weights and measures actually used in retail buying and selling, in the clothing trade, land measures, industries, farm products, rail and ship transportation. The replies furnish proof for his statements that nowhere is the metric system used exclusively, and that in countries that have adopted the metric system, the English system is also used, together with the original Spanish units, which, it is shown, differ but little from the corresponding Anglo-Saxon units. The author is of the opinion that the metric system has been pushed to the front chiefly by German influence, and as this has now been eliminated largely, it might be opportune at this time to unify the weights and measures of North and South America and the British Empire.

The aim of the author is to disprove: 1. The theory that it is an easy and simple matter for a country to change its system of weights and measures; 2, that the adoption of the metric system does away with confusion; 3, that this system is in universal use except in the United States, the British Empire and Russia; 4, that we must adopt the metric system if we desire to do business with Spanish America; 5, that the "adoption" of this system saves time in schools; 6, that it saves time in calculations, when in reality more conversions are made necessary by it; 7, that the persistence of old units in metric units is a persistence of names but not of things, which is not so; 8, that we will use the exact metric equivalents for English sizes. Reviewing the many unsuccessful attempts made elsewhere to install the metric system, the author is convinced that if it were to be adopted here in the United States it would only lead to needless confusion.

Discussion of Mr. Halsey's Paper

The paper evoked a very lively discussion, both sides being emphatic in the expression of their opinions. As usual with this

topic there were two groups; Mr. Halsey and his supporters looked at the question from the viewpoint of the manufacturer and the machine shop, while the opposite group was influenced by the theoretical or scientific advantages that it was believed would be brought about by a change to the metric system.

James Hartness, who opened the discussion, said that while he wished to be looked upon as a pro-inch man, and felt that the industrial worker preferred to adhere to this old-established system, he had a high regard for the scientist who is naturally in favor of the decimal and metric system. Realizing, as a result of the war, the need of close coöperation between all factions, and recognizing the fact that ultimately one system of weights and measures must prevail in international dealings, and in view of the present preponderance of Anglo-Saxon influence, he thought that one way out of the difficulty was to make the meter equal to 40 inches, as had been proposed in the past.

Howard Richards, Jr., Secretary of the American Metric Association, New York, emphasized the great simplicity of the metric system of measures, in which 1000 cubic centimeters or 1 cubic decimeter equals 1 liter or 1 kilogram of water. As is well known, in the metric system the meter for measuring length, the cubic decimeter or liter for measuring capacity, and the cubic centimeter of water or gram, are the related and fundamental units. He thought the utter simplicity of these units should commend the system to all who were favorably inclined to efficiency. He exhibited a 12-page pamphlet, issued by the American Metric Association, setting forth in detail the advantages of the metric system of measures. He challenged any one present to give him offhand the length of the side of an acre square, and elicited three replies, all differing and none exact.

Mr. Richards quoted Edwin M. Herr, formerly a vice-president of the Society and now president of the Westinghouse Electric & Mfg. Co., East Pittsburgh, as having told him, a few days before, that the Westinghouse Co. could make the change to the metric system by coöperating with the other engineers.

Henry D. Sharpe considered the work of Mr. Halsey as very valuable in that it disproved the claim made that there was urgent need of adopting the metric system to hold foreign trade.

Ralph E. Flanders was in perfect accord with what Mr. Hartness had said on the value of reconciling the needs of the shop man and the desire of the scientific engineer. He therefore offered the following motion, which was seconded by Mr. Hartness:

Resolved: That it is the sense of this meeting that the possibilities of the changing of the meter to forty (40) inches be brought to the attention of the Council of this Society, and that the Council be asked to consider such action as may lead to the adoption of this change by the metric countries.

Luther D. Burlingame said he had for years been interested in the subject of measures, and was chairman of the Society's Committee on Weights and Measures. It was a revelation to him to learn from Mr. Halsey's paper the extent to which the English system was used in Latin America, and to see how closely the important units of the old Spanish system agreed with it. He therefore found himself at variance with Dr. Samuel W. Stratton, chief of the Bureau of Standards, who had contended that the metric system was the most popular one in those countries. That the English system was acceptable to the twenty Latin-American countries was, according to Mr. Burlingame, proved by the fact that the total trade between the United States and those countries during the fiscal year 1917-1918 exceeded that of the year 1913-1914 by $1,000,000,000. He quoted Henry D. Sharpe, Treas., Brown & Sharpe Mfg. Co., as having said on this subject:

Instead of a change to the metric system being a benefit to our foreign trade, it would mean confusion to our home manufacture and use, placing a burden on us which would be a serious handicap in our competition for world markets.

Referring to Mr. Flanders' motion, Mr. Burlingame indicated that certain constructive steps had just been taken by the Society's Council, and that this was one of the matters that had led President Main to depart for Europe. Pending such negotiations, he would advise not to urge the motion before the house, because Great Britain was likely to take the initiative in the matter of unifying all measures, and we could afford to postpone definite action.

Mr. Burlingame thought that the paper was timely, and indicated a possibility for securing the adoption of the Anglo-Saxon system in Latin America, for which purpose he hoped a commission would be appointed to confer with representatives of those countries.

Adolph L. De Leeuw spoke rather in favor of the English system, and thought a 40-in. meter would greatly add to the confusion. He felt that the question of change of system had not been considered with an open mind. He said we should ask ourselves three questions: 1. If we had to choose a new system, would we select the metric or the English? 2. How much would it cost to change to the metric system? 3. Would the benefits be commensurate with the cost of changing? He would like to see fair play, and have the question definitely settled, whether or not the metric system was superior to the English. He said he knew from experience that it was a task to change metric dimensions or drawings to English dimensions, but that the change from English to metric would be no less awkward.

Samuel S. Dale, editor of *Textiles*, Boston, gave a lengthy discussion in favor of making the English system the universal standard. He showed that the present Spanish tables give the same multiples as the English, while the units themselves vary only 1.4 per cent from our units. He stated that in Russia the linear measures are based on the English inch and foot. The Chinese foot is equal to 12.6 English inches, but is divided decimally. The Japanese foot is 11.93 English inches. Even before the war, 70 per cent of the world's industrial energy was based on English weights and measures, and the situation at the end of the war precluded the adoption of any but the English system as a world standard. He called attention to the fact that British committees in reporting to Parliament regarding British policy after the war, did not recommend the compulsory adoption of the metric system, but held that a universal system would have to be acceptable to the British Empire and to the United States, and that in the meantime a simplification of the British system should be effected.

Mr. Dale said further that the object of such an inquiry was to remove the defects and equalities in the English system, which were but a mote compared to the mass of radical defects in the metric system, which we were asked to adopt. He welcomed the investigation suggested as tending to counteract what he called "pro-metric propaganda" by various Government Bureaus at Washington. He stated that Senator Shafroth of Colorado had introduced a bill during the preceding month (S. 5037) providing that the use of the metric system shall be compulsory in the Government departments, except in the survey of lands, after January 1, 1920, and that it shall be the standard of the country after January 1, 1922. He hoped the people would have a voice in settling this great question of change of system, because it should not be left to the "irresponsible theorists in the bureaus at Washington." He considered that the American Institute of Weights and Measures was best fitted to improve our English system and to oppose compulsory metric legislation.

Henry M. Hobart said he believed that a 40-in. meter would be equally unpopular with all parties concerned. Also that few realized to what a great extent the metric system was already established in the world. He was convinced that while working with the metric system in Germany his efficiency was higher than when he used the English system in Great Britain and the United States. He said it was not true that the British system was used to any considerable extent in Germany, but that the metric system was in use almost universally, as an inspection of textbooks would show. He thought this was the reason why Germany could produce so much more efficiently and cheaper than could the English-speaking countries.

Instead of adopting the 40-in. meter, he thought it would be simpler to await the death of the present generation, and regretted that in the intervening twenty years America and Great Britain must be allowed to fall behind in the matter of decimal systems

until younger men, imbued with more noble emotions, came to the front and caused the metric system to be adopted in this country.

Charles W. Johnson prefaced his remarks by stating that his viewpoint was that of a machine-shop man. He reasoned that if it was true that it took a year longer to educate a child in the English system than it did in the metric, that was an advantage, because it made him think, something he was supposed to learn how to do. Hence, the English system should be retained, for it is so complicated that it would make the child think!

Mr. Johnson wished to go on record as being decidedly opposed to the exclusive use of the metric system, for the sake of the operating men in industry. He said he had as yet discovered no advocate of a complete adoption of the metric system among industries manufacturing large varieties of complicated products where repair parts must be supplied. He thought the cost of retracing 500,000 drawings, converting inches into millimeters, would be prohibitive, and would bring no corresponding advantages. The method preferred now is to use even figures or simple fractions, because they are easier to work to than extended decimals. To employ metric units on new work only, he also thought to be impractical because of the mixed system of machine tools which would be necessary; besides, there were many old standardized pieces incorporated in new designs, so that the result would be great confusion. He referred to an article in the September 1916 number of *Machinery*, entitled The Metric Agitation, as being a clear and honest exposition of the conditions as affecting the machine shop.

Mr. Johnson added that if Latin-American business men preferred shipping papers to give weights and dimensions of packages in metric units, there was no objection to that, and that metric outline and foundation plans could be readily supplied, but he could not see why the parts themselves should be fabricated according to the metric system. He said it was most inopportune to make such a change now, because in the years following the war, with taxes high and labor conditions disturbed, it would be necessary to practice economy and efficiency more than ever. To be better able to meet competition, he thought we could not afford to expend millions of dollars in trying to introduce a system the benefits of which were apparent only to men of academic minds.

Charles E. Skinner said he represented the same company as Mr. Johnson. He was in favor of having but one international system, it did not matter which; but as to adopting the metric system, he was opposed for the same reasons Mr. Johnson had given, because he said the vice-president of the Westinghouse Elec. Mfg. Co. had estimated the initial cost of retracing their million drawings would be at least $1,000,000, with no compensating advantage; and, as he would be burdened with the task, he preferred to see things left as they are. Furthermore, the English-speaking peoples now occupied the dominating place in the world, and he thought they could retain it better by adhering to their present system.

D. E. Lauderburn said he had been practicing forest engineering since 1907, and had cruised timber in both the republics of Cuba and Santo Domingo. He found that the fundamental standards in these countries were metric, that the governments were using metric weights and measures, and that the surveyors used the metric system with the additional unit *caballeria*, which represented 42 metric hectares, the same as in Mexico. He exhibited a booklet published in 1910, in Spanish and English, entitled A Brief Statistical and Geographic Review, Including Revised Map of the Dominican Republic, on which map the only scale used was: 1 millimeter = 1 kilometer, and thought that especially for drawing and reading maps metric measures were a great convenience. He also exhibited a 28 by 63½-in. chart, published by the Cuban Department of Agriculture, Commerce and Labor at Havana, December 15, 1911, and signed by four government officials, giving all required technical data regarding 367 different kinds of wood. On this sheet the height and diameter of trees were given in meters, and the structural strengths expressed in kilograms per square centimeter.

After Mr. Sharpe had made further opposition to the resolution recommending consideration by the Council of the 40-in. meter, and Mr. Flanders once more had urged its adoption, Mr. Sharpe's motion, to lay this resolution on the table, prevailed by a rising vote.

Mr. Halsey, in closing the discussion, stated that the proposal for a 40-in. meter had been made frequently, the first time by Joseph Woodworth some fifty years ago, when it would have involved little difficulty to thus modify the meter.

His study of the New York schools convinced him that the study of weights and measures, instead of requiring a year, never exceeded three weeks. He said, "The judgment of the world is that the metric is not the better system, because the great majority of the people refuse to use it." He referred to France, where the metric system was first promulgated by law in 1792. In 1812, under Napoleon's reign, the law was repealed and people were allowed to return to their old system. He said this showed what the French people thought about this system, and that in South America they did not use it because they did not like it.

Upon motion of L. P. Alford, Mr. Halsey received a unanimous vote of thanks for his paper.

Written Discussions of Mr. Halsey's Paper

John H. Wigmore, Office of the Provost Marshal General, Washington, D. C., wrote that his attitude was based on the conviction that a system of weights and measures uniform throughout the commercial world, and decimal in its nature, was the obvious requirement; that he considered the Anglo-Saxon system as unscientific and impractical, and that the undoubted inconveniences of transition would be more than made up by the great convenience and economy of the future. Also that his opinion was strengthened by information he had received showing that in the engineering schools of the United States the metric system was used in practical work.

Representative James L. Slayden, Chairman of Committee on the Library, House of Representatives, Washington, D. C., wrote that he feared it would take considerable effort to secure the introduction of a really scientific and, when known, convenient system of weights and measures. He said that stupidity, inertia and momentary selfishness all operate to defeat the general adoption of the metric system in the United States. During his long and intimate acquaintance with affairs in Mexico, he had been greatly surprised to see how easily even the natives acquired a knowledge of the metric system, which was irresistibly making its way into the dullest understanding.

John B. Moore wrote that so long as Great Britain and the United States continued to do business in Latin-American countries with their old English units, those units were bound to be retained by those countries, unless their use was prohibited or penalized. He said that a uniform decimal system appealed very strongly to one's sense of convenience. On the other hand, he fully appreciated the fact that certain vested interests would be temporarily affected by the change, as well as the fact that changes are not generally desired by those who are not actually suffering from existing conditions.

H. J. Bingham Powell wrote that during his several years of experience as a civil and mechanical engineer in Peru and Bolivia, he found that in his line of work the metric system prevailed, but that manufactured articles imported from England and the United States, such as pipes, valves, cement, etc., were designated by their original units—inches, barrels, and timber in board feet. However, in workshops inches were in use rather than millimeters. In hydraulic calculations liters or gallons were used indiscriminately, the governments not attempting to make the metric system compulsory, since it would only inconvenience the people, who were satisfied with the mixed system of measurements.

William Jay Schieffelin, New York, whose drug business was founded in 1794, wrote that Mr. Halsey's report shows the chief obstacles to the wider use of the metric system in South America to be their business dealings with the English-speaking people. It certainly was not surprising to note the slow adoption of the metric system by the illiterate and conservative natives, but that was no reason for the people of the United States to be equally slow and to shut their eyes to the lessons of the past year, which

had demonstrated how quickly the whole people of this country could be informed as to an issue, if it was for the national good, and how within a few weeks the whole people would voluntarily cease using certain commodities, or change their habits of life, if it was for the country's good.

Mr. Schieffelin thought it ought not to take long to show a person having business dealings that a simple decimal system would save time and mistakes in merchandizing. In a wholesale drug house 30 per cent of the time of clerks could be saved if the weights and measures were metric. The fact that our blindness was not only hurting ourselves, but also our southern neighbors, ought to make us doubly anxious to put this reform into force.

Finally Mr. Schieffelin disapproved of the action of a small group of men, who were opposed to the adoption of the system, assuming an officially sounding name for their organization, and allowing their secretary to style himself a Commissioner.

Dr. A. E. Kennelly, Professor of Electrical Engineering, Harvard University, wrote that he could not agree with Mr. Halsey when he claimed in Par. 13 that Latin America was not metric. It was true, he said, that the use of the old units continued long after a new system had been introduced, especially among illiterate and the Indian people, but that ultimately the simpler system was bound to survive. None of the thirty-four countries that had adopted the metric system had ever revoked its decision, and those who had visited Continental Europe and the Latin countries knew from experience that the metric system was in universal use, and that if it were not satisfactory efforts would be made for the adoption of something better. Consequently he could not approve of the suggestion made in Par. 42 that "we should adopt the Spanish and not the metric system" if we were to succeed in selling goods to Spanish America. Nor could he agree with the idea suggested in Par. 9 that we should try to unify our system with that of the British Empire and South America, because then we should have to ask the International Metric Union, with its two basic units, the meter and the gram, to come into adjustment with our systems, with its dozens of units.

Professor Kennelly further said that the world was too small to permit of an indefinite continuance of a plurality of official systems. Sooner or later one system must prevail. When a simple and internationally recognized system operated alongside a complex and local system, it was only a question of time when the complex system must disappear. In fact, practically all scientific and electrical work was already being conducted and recorded in the metric system in every country. He stated that the American Institute of Weights and Measures could perform a great service to America and the world if it would, without bias, study means for bringing about international uniformity. That this could be done without abandoning existing plants, machines or apparatus was evidenced by the experience of other countries, only the adjustment would involve considerable readjustment of ideas, records and drawings. How to reduce this expense to a minimum, and how those burdened with the cost of changing over shall be protected and insured, were questions worthy of attention by the American Institute.

Mr. Gantt Presents His Paper on Efficiency and Democracy

In his paper Mr. Gantt establishes a relation between efficiency and democracy. He claims that the word "efficiency" has fallen into disrepute in connection with industry, and this at a time when efficiency is needed more than ever. He ascribes this to the fact that in the past the efficiency engineer has devoted himself exclusively to making more efficient the business of securing dollars, instead of producing more wealth. He says the production of goods for the benefit of the community is more important than the production of wealth for the benefit of those who control the industries. Also that the product of a factory should bear only the expense used to produce it, excluding the cost of idle machinery. There should be no idle machinery.

Mr. Gantt preferred to read only an introduction to his paper entitled Keeping the War Won. In this he pointed out that on the battle front war was competition in destruction. Behind the lines it was competition in production. He quoted Prof. C. R. Mann as saying that war was eight-tenths engineering, and that the engineer was the great production factor in the commonwealth. That through the efforts of engineers the war had been prolonged four years, and that it was certainly they who had won it. The next thing was to find out what part the engineer was to play in *keeping the war won.*

He then led up to the point where he hoped the engineer would be a more influential factor in the conduct of national affairs than heretofore, because he had demonstrated that *he knows what to do and how to do it.* He showed that when the war broke out leading business men had offered their services at Washington, but had found that their usual methods of doing business did not produce the required ships and shells, for they had been trained to operate for profits instead of for production. That engineers had attacked the problem in a different and successful way, he said, would be demonstrated during the discussion of his paper.

To supply the mechanical needs growing out of the war in sufficient quantity and in short time, progress charts had been compiled by engineers to show graphically the rate of production. These charts were used extensively by the engineering department of the Navy in the construction of shipyards, as well as in various large manufacturing establishments.

Mr. Gantt said that when the war broke out in Europe every one realized the necessity for greater production per capita, and it was the same in the United States. We should continue to improve our efficiency, and no machines should be allowed to be idle, so we could help those people who could do but little. If we did this we would also have the coöperation of the workman.

The system of keeping track of work done which Mr. Gantt had originated would be illustrated by a number of speakers who would show its successful application in the Ordnance Department, the Shipping Board, Emergency Fleet Corporation, and in numerous other places and private plants. He said that while the worker was studying efficiency, the engineer should study idleness.

Discussion of Mr. Gantt's Paper

Wallace Clark, the first to discuss the paper, made clear the task confronting the U. S. Shipping Board a year ago when it devolved upon that body to supervise ships afloat and building. He said the problem was to get ships to France and to bring to the United States food and raw materials. The former was done by the U. S. Army, and the latter by the Shipping Board. This Board had first ascertained what was needed at given times. Then it had listed its ships, which aggregated about 12,000, and it was here that the efficiency chart came in, inasmuch as it enabled one to have a graphical record showing in all required detail the daily movement of every ship, and to estimate beforehand the available carrying capacity in any direction for several months ahead.

The speaker then had a few typical charts projected on the screen. The first showed the rate of import of nitrate from Chile to this country. Of this, 800,000 tons, or more than half the output, was called for in the course of the year. To this work 175 ships were detailed. Charts, apparently 11 in. by 17 in. in size, were ruled up in such a way that the vertical columns represented days, weeks and months, proceeding toward the right. The descriptive side heads for the horizontal columns were placed along the left-hand margin. From these toward the right were drawn heavy black lines of differing lengths, the length of the line indicating either the quantity required up to the date indicated, or the actual output—or both if parallel lines. In the case of the ship record there was one horizontal column for each ship. One could tell from the record the weight of cargo, how long it took each ship to make a round trip, and when it could be expected to arrive. At the end of each month the various burdens could be added up and note taken of the progress made. It was possible to observe from these charts the over-supply as well as the deficiency of about 100 necessary commodities, and this furnished the required means for regulating the activity of the ships.

Another slide showed a similar chart applied to recording the progress made on certain field-artillery mechanisms. Each mechanism had to go through 67 different operations in manufacture.

The desired output was 10 mechanisms a day, and if the lines or bars on the chart were all of equal length, that would mean 70 mechanisms completed each 7-day week. However, the charts showed that some operations were proceeding at the proper rate, some were ahead, while others lagged behind, their lines being short, and therefore demanded special effort in order to meet promised deliveries of completed sets.

A. T. Clark, another member of the U. S. Shipping Board, then exhibited some slides of charts showing the movements of over 7500 ships employed in supplying coal from Chesapeake points to New England ports. Instead of a single horizontal bar, a series of circles and special characters were placed in the horizontal column for each ship, at the required dates. A circle represented the face of a clock, a closed circle denoting a full shift of 10 hours' work. A symbol inside of an incomplete circle gave the reason for any idleness. Thus, a wavy dash meant adverse tides or bad weather.

The cards were 11 in. by 17 in., each side for six months. For each month there were six horizontal lines, A to F. The dotted line A would show at some date a forward "L," indicating the date the ship left port. Some days later, on the same level, there would appear "L" turned the opposite way, indicating arrival at the distant port. The next distance, between brackets, indicated the time spent in port. Name of ship and tons of coal or other load carried were marked in the open space between the brackets. After the second bracket was written the name of the port bound for. While in port a separate symbol signified "discharging cargo," another "discharging ballast"; the relative position of the symbol indicating whether the work had been done by day shift or night shift.

On the chart was also indicated the time consumed in discharging the cargo each time, also how the ship was held up waiting for dock accommodation, and whether the ship had to undergo repairs which may or may not have interfered with loading or discharging. At the end of the month a cost statement could be prepared of the transportation cost per ton over this route. A new chart was then made providing a vertical column for each ship. The height of this column represented the total cost, and that was made up of the various items that enter into the cost of transportation. This showed the performance of each ship, the shortest column indicating the lowest cost per ton carried.

W. H. Blakeman submitted a written discussion which was presented by Mr. Gantt. Mr. Blakeman, he said, was a shipbuilder, now connected with the Cramp Shipbuilding and Engine Co., previously employed by the American Shipbuilding Co., headed by the Emergency Fleet Corporation, to help them to standardize work in shipbuilding. After looking over the Philadelphia plant, Mr. Blakeman devised a progress chart which greatly facilitated the production.

The facts intended to be conveyed by graphical straight-line charts included the following:

1 Show the work to be done on various parts of the vessel
2 Indicate manner of doing it at the shipyard decided on
3 Indicate time of completion of all parts.

The adopted form of schedule and progress charts record:

a The work to be done in groups
b When it is to be done.

Vertical columns on the charts represented days. Horizontal columns applied to the various items of work. Along these horizontals were marked various characters and symbols showing state of progress at the date they appeared. The rate of receipt of structural material was thus apparent from the charts, the rate of erection, rivet driving, installation of equipment, etc. The Emergency Fleet Corporation was instrumental in having this simple and effective chart system introduced at 90 per cent of all the shipyards in operation in the United States.

S. B. Barrows, a representative of the Naval Aircraft Factory, Navy Yard, Philadelphia, then described and had shown on the screen a number of the Gantt type of progress charts which had proved to be very valuable in systematizing the proper rate of production of completed airplanes.

James J. Reynolds then illustrated on the screen charts devised, with the assistance of Mr. Gantt, for accelerating the production of artillery ammunition at the Frankford Arsenal. Blueprints of these charts could be sent to Washington at regular intervals, and thus information imparted without entailing the vast amount of correspondence previously required.

H. J. Swallow, of the Emergency Fleet Corporation, also had shown a number of record charts that were found necessary for procuring in due time the thousands of articles necessary in the completion of ships.

Captain Charles E. Davis illustrated the use of the Gantt progress charts as applied to the manufacture of fuses. He stated that the charts had been of great service in registering the rate of production and the relative efficiency of the departments.

John E. Mullaney showed charts used for greatly facilitating the production of complete machines, and indicating at once when a portion of the equipment was not producing its rated output.

Major Frank B. Gilbreth then made a motion, which was seconded by C. B. Johnson and carried, that Mr. Gantt be asked to submit to the Society a general progress chart for the use of all businesses, embodying his latest ideas—a chart that could be used as a standard.

Walter N. Polakov was in hearty accord with Mr. Gantt's ideals in regard to efficiency and democracy. He thought the time had now come where a reorganization of the industrial system in the United States was in order, to supersede the old business system which involved so much waste. He commended the British Ministry of Reconstruction for stating that "the work now for the world is to establish fresh and fair conditions wherein social and industrial life may thrive unhampered as never before."

He said the old standards were definitely changed, as had to be the inevitable outcome of a war waged to make democracy safe, and that a man was judged today not by the size of his bank account, but by his record of deeds. In his opinion, the task for engineers is threefold: (1) We should lead in extending credit and authority to those who know how to do things and whose records show that they have done them. (2) In industrial relations we should adopt the principle of "no secret agreements," so that workmen would know what the management does, and one manufacturer would know what the others were doing, and that the people should know what things cost. (3) We should control all our natural resources the same as public funds are controlled, and not allow needless waste. As an organized body of engineers we should set an example of a government by facts.

Mr. Gantt, in closing, said that the exhibition of many performance charts from all sorts of plants had been for the purpose of proving their wide applicability.

After the war had broken out he had gone from the Frankford Arsenal to Washington to see General Crozier to discuss questions of organization. His method of charting production appealed to the General, and it was introduced at once, so that by November 1917 about three-quarters of the production in the Ordnance Department was charted by it in detail. In addition the method was welcomed by a large number of plants throughout the country, as had been just shown.

It developed later that in November 1917 Professor Schneider, Dean of the University of Cincinnati, had also been invited to Washington by General Crozier to confer on labor problems. Early in December the Dean handed Mr. Gantt a copy of his report made early in December 1917 to General Wheeler, at that time General Crozier's first assistant, in which he had recommended for adoption by the entire War Department the production charts already successfully applied by the Ordnance Department. Mr. Gantt said that just about that time Congress met and criticism developed. Business men from all over the country went to Washington to help straighten out matters. These men were mainly financiers and salesmen not acquainted with production. They did not understand that Washington's problem was one of production and hence that an organization such as General Crozier's was built primarily for production. The organizations which they understood were built primarily for profit; but the country did not need profits, but goods.

The result was that General Crozier was ousted and his whole plan of organization of the Ordnance Department went to pieces.

Although General Crozier's plans had been thus disrupted by his successor, a start on the same lines had already been made in the U. S. Shipping Board, and from there the methods gradually spread to other Government departments, including finally the arsenals. Had the original plans of General Crozier been carried out, Mr. Gantt believed there would have resulted less trouble in the supply of ordnance and many lives lost in France would have been saved.

EFFICIENCY AND DEMOCRACY[1]

By H. L. GANTT, NEW YORK, N. Y.

WHY has the word efficiency, which should stand for so much, fallen into disrepute in this country? That it has fallen into disrepute cannot be gainsaid, both with the business man and the workman. We all recognize the importance of both individual and collective efficiency. This being true, there must have been some fatal error in the management of the campaign which at the end of twenty years has made the very name a byword.

It is not to be questioned that many men who have devoted their time to this subject have very much improved our industrial processes and the productivity of our manufacturing plants. Yet in the mind of the average business man or mechanic the term "efficiency engineer" raises a feeling of hostility.

Today we need efficiency, both individual and collective, to a far greater extent than we ever needed it before, yet it seems that we must do the work of promoting it under some other guise if we would really have it accepted and approved.

To some of us the reason seems plain, simply that we have in the past measured the "efficiency of our business" by the dollars acquired rather than by the goods produced. The efficiency engineer of the past has in too many cases devoted himself exclusively to making more efficient the business of securing dollars. In other words, he has served the business system primarily in the accumulation rather than in the production of wealth.

A business system bent on the accumulation rather than on the production of wealth, which would even curtail the production of wealth if thereby a larger measure could be brought into its own coffers, must needs finally run to the limit of its tether, and a method which makes more efficient such a system shortens the time which it has to run. An efficiency engineer who, consciously or unconsciously, served the business system in the exploitation of workmen, necessarily got the ill-will of the workman. He later got the ill-will of the business man, who found that the amount of wealth he could get by exploitation was strictly limited. I am not claiming that all efficiency engineers have done this, nor that even those who have done it have been conscious that they were producing a condition to which there must be an end. They were simply serving "business as usual," which puts more effort in harvesting the crop than in producing it.

When the great war broke out in 1914, it became evident to all those who gave it serious consideration that the production of goods for the benefit of the community, and not the production of wealth for the benefit of those who control the industries, was the task which had been set the nations engaged. It took England more than a year to learn this lesson, and we should have been fully prepared for it in 1917 when we were drawn into the maelstrom. That we were not prepared for it, and that many believed we could still continue business as usual, is now history. We have learned, however, that production for the benefit of the community was the only basis on which we could carry the war to a successful conclusion. This has been emphasized by the elimination of "non-essential" industries.

There is another reason why the term efficiency has been brought into disrepute. In the past our cost-keeping methods have always loaded on to the part of the shop which produced the goods the total expense of the shop, including the part that was idle. For instance, in a shop having two expensive machines, it was the habit to load on to the product the expense of both machines, whether the goods were produced by one or by both. Under such conditions, if one machine did the work of two, the product was still charged with the expense of both, and the full benefit from the increased efficiency was not apparent to the owner, who saw only the saving in wages. He did not see the saving in plant. He did not comprehend clearly that if he doubled the output of his machine he could double the output of his plant without additional expense. In other words, that he was also making his capital twice as efficient. It is hard to see why he did not see this, except that the system of cost keeping seemed designed to hide it. The term "efficiency" then seemed to have no connection with capital on investment, but only with labor.

Under such conditions there was but little inducement to the owner to make his machines produce more, and the reverse of an inducement to the workman, who was thereby laid off or saw his friend laid off. This fatal error which caused the opposition of the workman, and the lack of sympathy on the part of the employer, was evidently due to a false accounting system, which was devised to put all the burden of inefficiency on the workman.

When the great war started in 1914, and the wheels of industry slowed down to such an extent that it was impossible for the product turned out to bear the expense which had previously been distributed over a production three or four times as large, most people said, "These are extraordinary times; therefore we shall have to lay our cost system aside till the war is over."

Some people, however, realized that a system which is not good for an emergency, when it is most needed, has something radically wrong about it, and set to work to find out what the flaw was, and this was the answer they arrived at:

The product of a factory must bear only the expense used to produce it. It cannot bear the expense of idle machinery which did not contribute to its production. This statement is such a radical departure from the ordinary cost-keeping system that it produces a shock to the business man who has a theory that he must somehow or other get back all of his expenses. He seems to feel that he is entitled to interest on all the money he has invested, whether it produces anything or not. Under such conditions he is not seriously worried so long as he can sell his product for a price high enough to give him the profit he considers himself entitled to.

Some of the keener business men, however, have seen the flaw in this argument, and have realized that idle capital is no more entitled to wages than idle labor, and have begun seriously to study their plants to find out how they can use them to their full capacity. The result of this investigation is twofold:

a It does not result in laying off men, but gives employment to more men, which secures the good-will of the worker.

b It not only reduces the expense of maintaining machinery in idleness, but turns out a greater product from which revenue is gotten.

Some would say that this is a beautiful theory, but it doesn't work that way. I answer unhesitatingly, after more than three years' trial, that it does not work that way and that none of those people who have adopted it would for a moment think of going back to the antiquated method of cost keeping which they have given up.

The keynote of such a system is the elimination of idleness and the production of goods. Moreover, there is no antagonism in such a scheme between employer and employee, for each gets the reward for what he does.

To the conservatives this would seem almost revolutionary, and fraught with consequences of which they cannot see the end, but it is democratic and absolutely in harmony with the patriotic doctrine which is being preached. It enables us to change automatically our slogan of "business as usual" into "business for production and victory."

In a few words, then, if we eliminate our false cost-keeping methods, and put in those that are correct, we shall not only benefit both employer and employee, but go a long way toward the democratization of industry.

---

RAILWAY ARTILLERY

By COLONEL JAMES B. DILLARD,[1] U. S. A.

Contrary to general belief, railway artillery is not a recent development of ordnance. In 1863 a 13-in. mortar was used by the Union Army against the defenses of Richmond. It weighed 17,000 lb. and was mounted on a flat car having eight wheels. Some 4-in. artillery pieces were also used on railway mounts. In 1883 Gen. Joseph L. Brent wrote a book on the subject of railway artillery, in which he prophesied accurately its development as has occurred during the European war, and even anticipated the armored automobile and the tank.

Both the British and Boer forces in the South African war utilized naval or coast-defense guns on railway cars. In the campaign for the relief of Ladysmith the British used four 12-lb. naval guns on flat cars. Armored trains, mounting field guns, were also used.

In 1893 the Schneider Co., of France, brought out a type of disappearing carriage mounted on wheels for road transportation. The St. Chamond Co., of France, brought out a similar design, but mounted upon a railway car. The weight of this 4.7-in. gun and mount was about 20,000 lb.

In 1900 the Schneider Co. made up a 155-mm. howitzer mounted upon a car which closely resembles the design used today. The Skoda Co., Austria, brought out a design of truck mounting to secure greater mobility for light coast-defense guns calculated to travel a short distance only.

A few years later the St. Chamond Co. had improved its 1892 model, the gun still having a disappearing carriage, but well mounted on a short railway truck equipped with rail clamps to secure increased stability under firing strain. It had also a horizontal armored shield overhead for the protection of the gunner. Since then it has been found that the rail clamps are suitable only for guns smaller than 6-in., as heavy guns pull the rails and ties out of the roadbed.

About this time the Krupp works in Germany built a 4.7-in. railway gun which was simply a wheeled road gun with disappearing carriage placed on top of a flat car. Rail clamps and outriggers appear in this design; the latter consist of swinging brackets with vertical hinge pins and jack screws at the outer ends, and serve for bracing the car during firing.

In 1912 the Schneider Co. brought out a design for a 200-mm. howitzer which is now typical of our present ideas for mounting guns up to 8-in., and mortars up to 12-in. The howitzer is mounted on the usual type of barbette carriage, in that it can fire in any direction, and is placed upon a drop-frame car. A folded platform is used, also outriggers.

Fig. 1(*g*) shows an American design of about 1912 for a 4.7-in. howitzer, which is very similar to the Schneider.

In the foregoing cases the main object was to devise a mobile weapon for coast defense, but in the European war the use of railway artillery was confined to field operations, no coast-defense necessities having arisen.

Types of Cannon Used on Railways

The types of cannon mounted on railway cars are the same as those used in field and seacoast artillery, and include mortars which are 9 to 12 calibers (diameters) long; howitzers 15 to 20 calibers long, and guns which vary in length from 30 to 50 or more calibers.

Mortars are used for "plunging fire"—they are fired at angles of elevation of 45 to 65 deg., the projectile dropping nearly vertically on its objective. The mortars used by the American Army are of 12-in. bore, 9 to 15 calibers long, and their muzzle velocity ranges from 900 to 1800 ft. per sec. On railway mounts they can be fired at angles of 20 to 65 deg. The weight of projectile is 700 lb., and the maximum range is 15,500 yd. The modern trend is to abandon the mortar, because its only advantage is that it is cheaper and will perform certain limited functions as well as the howitzer.

Howitzers are fired at angles of elevation from 30 to 65 deg. The American Army uses howitzers of 6 to 16 in. bore having a muzzle velocity of from 1500 to 2000 ft. per sec. Only the 16-in. howitzer has been mounted. It fires a 1600-lb. projectile with a muzzle velocity of 2100 ft. per sec., which, at a 45-deg. elevation, gives a range of about 24,000 yd.

Guns are used for accurate work at long range. The German guns which bombarded Paris were doubtless 60 to 70 calibers long. Until the present war, guns were normally used for direct fire at elevations not exceeding 20 deg. Recently, however, they have been used at elevations up to 45 deg., to obtain the maximum range possible.

Accuracy of firing at these high elevations and long ranges is, however, small, as the German gun required a target of the size of the city of Paris and was not always able to hit even that. The range of the guns in our service, which vary from 8 to 14 in. is from 13 to 30 miles. The projectiles vary in weight from 200 lb. for the 8-in. gun to 1400 lb. for the 14-in.

The accuracy life of the mortar is estimated to be about 5000 rounds; of the howitzer, about 2000 rounds; and of the gun, about 150 rounds. After firing this number of shots, the fire becomes inaccurate owing to the wear in the barrel.

Problems of Design

The two main problems in the design of railway mounts are transportation and provision for stresses due to gun firing. The transportation problem requires that the closest consideration be given to weight, minimum railway clearances, and a full understanding of car design, especially as pertains to the trucks. To handle mounts weighing 600,000 lb. and upward a system of trucks must be utilized that combines perfect equalization of loads and flexibility.

The condition of road beds in France has limited all axle loads to not over 17 metric tons. For mounts designed for use only in the United States this might be increased to 22 tons, but so far all the railway mounts, with the exception of the 8-in. gun, have been limited to the maximum weight allowed by the French railways.

The railway clearances set by tunnels, bridges, third rails, etc., present a considerable handicap and impose several limitations upon the design. Fortunately American and French line clearances differ very little and provide for a maximum height of about 14 ft. at the center of the track and a width of 10 ft. Fig. 2 shows on the right the French, and on the left the American, clearance diagram as applied to the 8-in. gun railway mount.

The American Army has made a careful study of the clearance diagrams of all United States railways to insure that all our mounts will be capable of being used in any part of the country. With guns up to 8 in. and howitzers up to 12 in. the limitations to design set by the railway clearances are slight, but in the case of howitzers of 16 in. and up, and with guns 12 in. and up, the limitations of the clearance diagram begin to be severely felt.

The gun is elevated around its trunnions, which are usually located at the center of gravity of the tipping parts. The breech end of a 12-in. gun when tilted around its trunnions would strike the cross-ties at about 30-deg. elevation, 25 deg. elevation for the 14-in. gun, and a less elevation for the 16-in. gun. In order to secure a greater elevation it is necessary to modify the design by any one of the following methods: The gun is artificially thrown out of balance by placing a weight at the breech end. A mechanical counterbalance device, such as springs or compressed air, can also be used. In this case a column of springs or a compressed-air column is so lined up with the elevating gear as to compensate for the muzzle preponderance when the

trunnions are located to the rear of the center of gravity of the gun. A third method is to provide a top carriage carrying the trunnions of the gun and to raise this sufficiently high into firing position by means of hydraulic jacks to enable the breech to clear the ties.

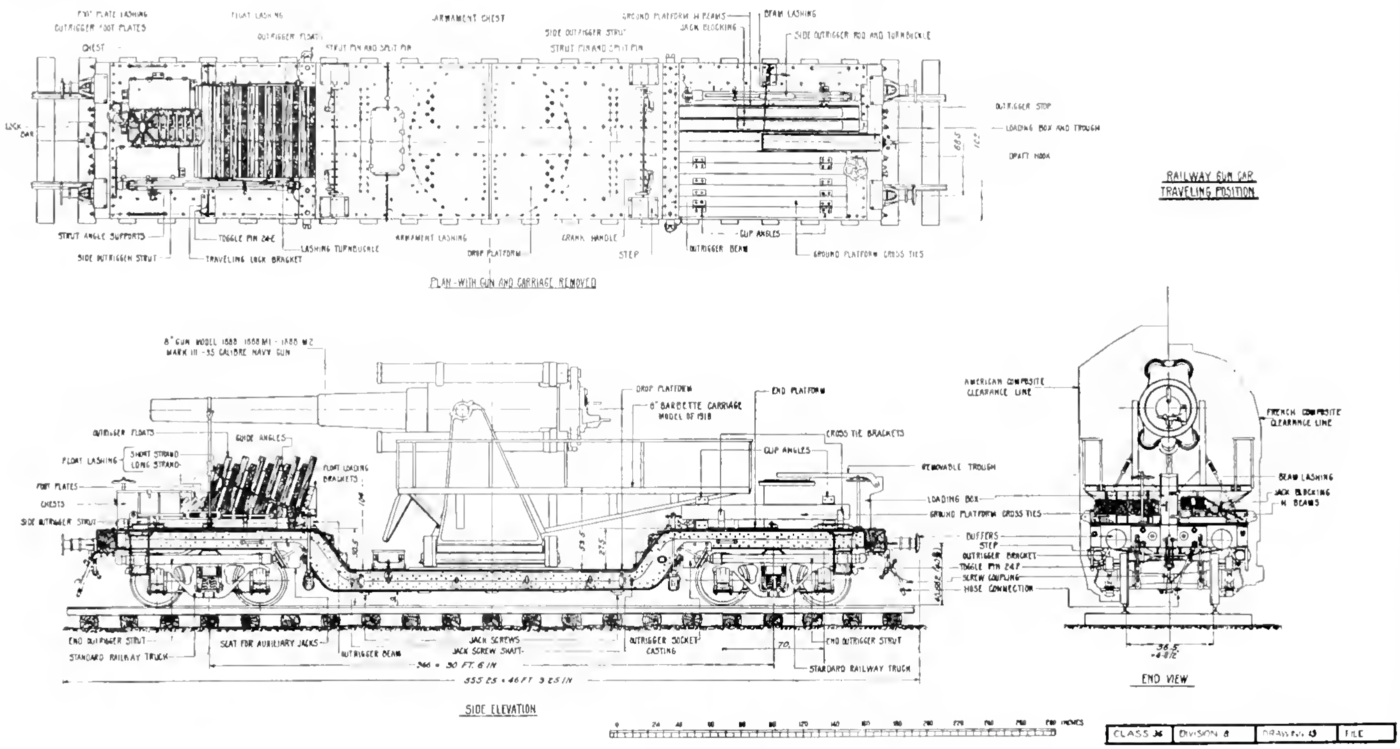

Fig. 2 8-in. 35-Caliber Navy Gun Railway Mount in Traveling Position

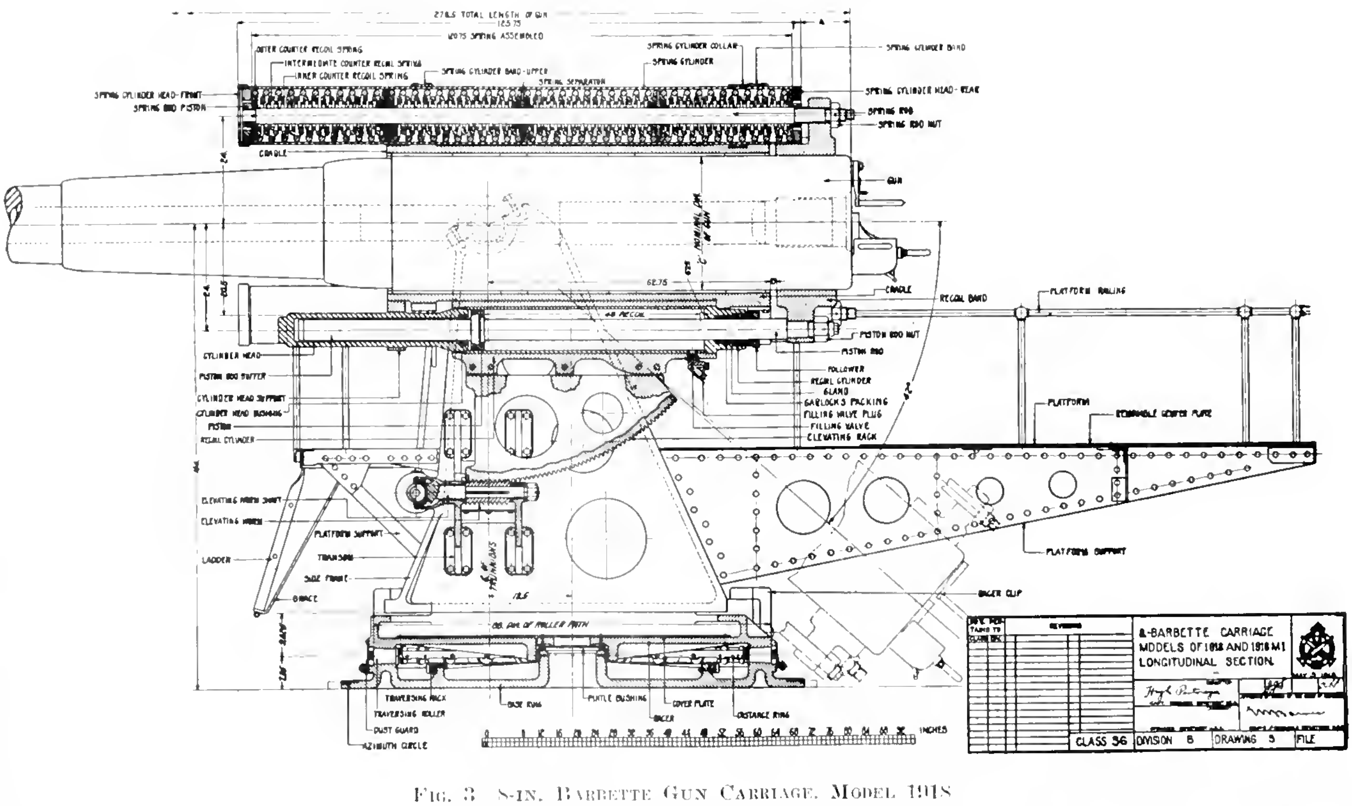

Fig. 3 8-in. Barbette Gun Carriage, Model 1918

The fourth but least desirable method is to dig a pit in the line of the railroad track, but this requires a specially constructed track to bridge over the gap caused by the excavation, besides there may not be time available to make the excavation, especially when the ground is frozen. All of these alternatives have been utilized in the various designs of railway mounts, but the simplest and best is the use of the counterweight, as there are no moving parts involved.

In providing for stresses due to gun fire, it must be remembered that the mounts should permit of elevation up to 45 deg. in order to secure the maximum range obtainable. The widest possible traverse should be aimed at, 360 deg. if possible. It is comparatively easy to obtain the elevation desired, except with the 16-in. size and upward, but it is not possible to obtain more than about 10 deg. total traverse with the railway mount unless

considerable time is allowed for preparing a firing platform other than that provided by the car itself.

For guns up to 8 in., and howitzers and mortars up to 12 in., an especially designed drop-frame flat car can be used and the barbette carriage of standard construction placed upon the car. Fig. 2 shows the 8-in. gun railway mount, model 1918, as designed by the Ordnance Department.

With larger guns various designs have been produced for use in the present war. Most of them provide for a 2- to 6-deg. traverse on either side of the center of the gun, greater change of direction being obtained by using the curved track. Even this arrangement places a handicap upon the tactical uses to which these guns may be put.

Barbette Carriages for All-around Fire

These carriages are of the standard barbette type. In fact, the carriages may be removed from the flat car and mounted upon a concrete base as is the practice in many of our seacoast forts. The carriages are always provided with recoil and counter-recoil mechanisms. The force of recoil is checked by forcing a liquid in the recoil cylinder, usually oil of about 0.85 specific gravity, through two or more orifices cut in a piston, the piston rod being attached to the breech of the gun, while the recoil cylinder is attached to the cradle.

Counter-recoil is accomplished by means of helical springs, usually about four columns, or by means of compressed air contained in an air bottle located above the center line of the gun. The 8-in. gun carriage has a spring counter-recoil mechanism as shown in Fig. 3, while the 12-in. mortar carriage has the compressed-air counter-recoil mechanism (air recuperator) illustrated in Fig. 4.

With the larger guns compressed air is preferred on account of the less bulky mechanism required. Figs. 3 and 4 show also the type of elevating mechanism used, which includes a worm and worm-wheel sector. The traversing gear consists of a turntable resting on conical rollers, which in turn rest upon a bedplate attached to the body of the car.

The design of limited-traverse railway mounts for guns and howitzers presents but few engineering difficulties. The principal one relates to the height at which the trunnions must be placed in order that the breech of the gun may not interfere with the road track. Fig. 1(*b*) is typical for this type. The trunnion of the gun rests upon girders which are supported at each end by trucks. It is evident that by means of the curved track a reasonable amount of traversing is available.

In the case of the all-around firing type of mount for large guns and howitzers, it is necessary to have some form of firing platform on account of the varying direction in which the firing stresses may act.

During 1915 the Ordnance Department started the design of the 14-in. mount, Model E, shown in Fig. 1(*b*). A base ring with a conical roller path is carried in a separate car, and is to be set into the ground. The gun and mount on its traveling trucks are run over the base ring so that center of the car is over the center of the base ring. The mount is then jacked up so that the traveling trucks may be disengaged from the girders. The mount is then lowered so that it rests upon the conical roller path, where it is free to be traversed in any direction. This arrangement has also been applied to the construction of a 16-in. howitzer railway mount.

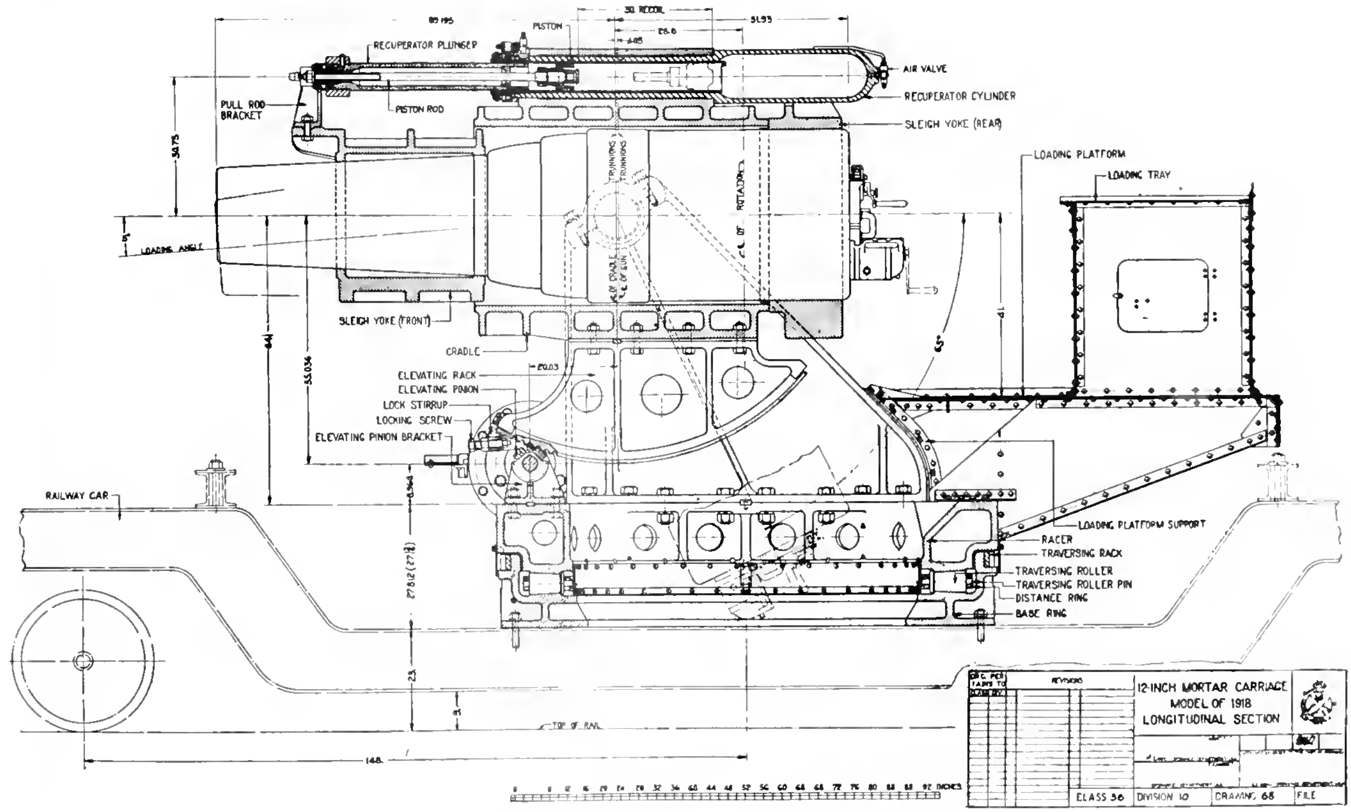

Fig. 4 12-in. Barbette Mortar Carriage, Model 1918

Foreign Types of Railway Artillery

A number of French howitzers have proved very satisfactory during the present war. They include the 190-mm. (7.6-in.) and the 240-mm. (9.6-in.) howitzer railway mounts with movable top carriages. These mounts are not provided with a traverse mechanism and therefore must be moved along a curved track to obtain azimuth setting. Due to the lack of long-range field artillery at the beginning of the war it became necessary for the French Government to construct with the greatest of rapidity considerable quantities of railway artillery, and to utilize naval and coast-defense guns already in existence. Schneider & Co. then designed what they termed a "glissement" or sliding railway mount, an example of which is shown in Fig. 1(*h*).

These mounts consist of two six- or eight-wheel railway trucks

connected by heavy girders which carry the weight of the gun. These girders are provided on the lower surface with cross-beams connected to the girders by jack-screws. Before firing, these cross-beams are lowered on firing rails thus relieving the trucks of the firing load, which is transmitted directly to the roadbed. No recoil mechanism being provided, the recoil force is taken up by the friction of the entire mount sliding backward on the firing rails.

No traversing mechanism is provided, direction in azimuth being obtained by constructing the firing track on a curve. After the shot is fired, it is necessary to move this gun forward to its original position which is done by hand through a system of sprockets and chains to turn the wheels of the trucks.

Fig. 1(*c*) shows a 340-mm. (14-in.) railway gun built by St. Chamond. The gun rests in a cradle, which is a large ribbed casting through which the gun slides in recoil. The cradle has trunnions which are carried in trunnion bearings on the top carriage, which is supported by the car frame mounted on trucks. The firing emplacement consists of a pit into which the gun recoils when firing at higher angles. Two platforms which act as a foundation for four jacks provided with large timber floats prevent the car from recoiling along the track. The shock of recoil is absorbed by hydraulic cylinders and the gun is returned to battery by an air recuperator. The top carriage can traverse about two degrees.

The 14-in. British railway gun is almost identical in design with Fig. 1(*c*). The gun is 62.5 ft. long, weighs approximately 183,000 lb. and is mounted in a cradle whose trunnions are supported by two longitudinal girders carried on two sets of four-axle trucks. The total weight of this mount is approximately 545,000 lb. With this gun a traverse of 2 deg. on either side of the center line is provided for. In order to secure a high elevation the gun is placed forward in the cradle so that it has a considerable amount of muzzle preponderance. This unbalanced weight is compensated by a pneumatic counterbalance device so that the piece may be easily elevated. The recoil mechanism consists of two hydraulic cylinders and the gun is returned to battery by a pneumatic cylinder. The elevating mechanism consists of a screw operated by a gasoline engine.

American Types of Railway Artillery

Fig. 1(*e*) shows a barbette carriage mounting a 7-in. 45-caliber gun, a design developed by the Ordnance Department. The carriage and gun were originally designed by the Navy Department and were mounted on certain battleships and cruisers. A number were available for army use and were mounted on the railway car with drop frame as shown. This car construction is now standard with the Ordnance Department for similar sizes of guns and mortars and provides for 360 deg. traverse. Fig. 1(*j*) shows the construction of this type of mount. The trucks used are Pennsylvania Railroad standard 70-ton freight-car trucks. A firing platform and outriggers are necessary to brace the mount against the ground to take up firing stresses. Each outrigger consists of a pipe attached by a ball-and-socket joint to the car frame, the lower end having a screw jack which rests on the wooden float sunk in the ground. The jacks for raising and lowering the car are built in the structural part of the frame and are operated by ratchet levers. The total vertical movement required for the insertion of the oak cross-ties in the firing platform is about one inch. The mount may be put in firing position by a gun crew in 15 to 20 minutes.

The 1918 model 8-in. gun railway mount, which uses the same barbette carriage as the 7-in. gun, Fig. 1(*e*), may be elevated from 0 deg. to 42 deg. It fires either a 200- or 300-lb. projectile at a maximum muzzle velocity of 2000 ft. per sec., and has a maximum range of about 23,000 yd.

By means of special 8-wheel trucks it is possible to transport this mount over a 60-cm. (24-in.) narrow-gage track. This 8-in. mount weighs about 180,000 lb. and it certainly is a great advantage to be able to transfer it to a narrow-gage track which is the kind used at the battle front in order to better conceal operations. On the narrow-gage track a speed up to 15 miles per hour is feasible. The Ordnance Department, who developed this mount in its entirety, considers this artillery piece to be the last word in railway mounts. It is also the only mount of its kind in existence.

Fig. 1(*e*) shows a 12-in. mortar placed upon the same car as the 7-in. and 8-in. guns, except that 6-wheel trucks are used in place of the standard 70-ton 4-wheel trucks. It is also adapted for narrow-gage track and makes a highly satisfactory piece for field and seacoast work.

Fig. 1(*h*) represents also the American sliding type of railway mount. It has neither recoil mechanism nor traveling mechanism. It is a 12-in. gun and the entire mount is about 105 ft. long and weighs 575,000 lb. It can be transported at the rate of 40 miles an hour over standard-gage road bed and will go around any curve met with in American or French railway practice. When the gun is to be used, the track is laid on a curve and the gun is turned on its objective by moving the mount back and forth by means of a gasoline engine. A special hand translating mechanism is used for spotting the mount in the exact position.

The principal parts of the car body consist of bridge girders, span bolsters connected to 8-wheel trucks, trucks, bearing stringers and sleepers, lifting wedges and loading mechanism. The gun is supported on trunnion beds, which are carried on top of the girders. The gun can be elevated from — 4 deg. to + 40 deg. The slippers consist of wooden beams placed crosswise under the car body, supported by the elevating wedges which raise and lower them into position. The bearing stringers are made up of eight lines of 12-in. steel I-beams. The lifting wedges are operated by handles, one man being placed at each handle. No special track preparation is necessary other than to lay the stringers and to see that the track is well ballasted. In the firing the entire piece slides to the rear for about 15 ft. and after each shot the mount is returned by means of the power winch and the hand translating device. The 12-in. gun used is 50 calibers in length and is one of the most powerful in existence. The muzzle velocity is 3200 ft. per sec. and the range is approximately 30 miles.

Fig. 1(*a*) illustrates what is considered the very latest type of railway artillery. This mount carries the 16-in. howitzer developed by the Ordnance Department in 1918, which is the most powerful howitzer known. The carriage embodies the features which are considered the most desirable in handling railway artillery for field-army use. The howitzer can be fired on this mount directly from the trucks on standard-gage track. The track emplacement and bearing stringers to take up the shock of recoil are done away with. The shock of fire is taken care of in the recoil and in pushing the car backward along the tracks on its own trucks. For this duty unusually heavy trucks are necessary to absorb the shock and to transmit it to the roadbed. The piston-rod pull is approximately 670,000 lb., which force is transmitted directly to the trucks. Two 12-wheel trucks are used with specially designed frames and springs. The top carriage is pivoted at its forward end, and arranged at its rear end so that 12 deg. traverse is all that is necessary for range correction, the range direction being secured by running the mount on a curved track. A gasoline winch is placed on the forward trucks which pulls the mount back to its original position by means of a cable attached to a rail clamp. Four columns of counter-recoil springs are used. The loading arrangement is the American style of gravity platform, which permits the projectile to slide into the breech.

Fig. 1(*b*) illustrates the 14-in. Navy gun railway mount built by the Navy Bureau of Ordnance. Some 14-in. 50-caliber guns that were not required aboard ships were utilized and mounted on railway trucks. Four 6-wheel trucks are used and connected by span bolsters upon which rest the body girders. Top girders support the gun and its cradle by means of the usual trunnion and bedplate. A cab, consisting of ¼-in. armor plate, encloses the body girders, as well as the breech end of the gun. The emplacement, of structural steel, is carried on special cars and is placed in position by a locomotive crane. Four jacks are used to relieve the trucks of the firing shot. Five degrees traverse

is secured in place, and 45 deg. elevation. This amount of elevation necessitates a pit of 9 ft. in depth.

Auxiliary Cars

All railway artillery operates in batteries which are made up of four gun mounts with their auxiliary cars, including ammunition firing cars, control cars and supply cars. The ammunition car is especially designed and standard for all railway artillery. It is a steel car provided with a trolley I-beam and hoist for handling ammunition. The ammunition is stored in racks, Fig. 5, which are so arranged that they can be taken down and the car used as an ordinary box car. The fire-control car is a standard Government 30-ton box car provided with windows. It is used as an office by the battery commander and contains fire-control instruments. The supply car is a standard Government 30-ton flat car on which is carried the auxiliary equipment and the supplies that are to be used with heavy railway artillery.

Tactical Uses

The uses for railway artillery are considered under two principal heads, namely, against land targets with field armies; and for coast defense. Guns, howitzers and mortars are required for these purposes.

For use with field armies the ability to bring the mount into and away from firing position is of more tactical value than an extremely wide traversing angle without moving the location of the gun. On the other hand, for sea-coast defense a wide, quick and accurate traverse without changing the location of the gun mount is an absolute essential. One of the greatest values which railway artillery can have to the United States is the ability to concentrate large numbers of guns within any given strategic area. If guns are made up in trains, they can be moved quickly from one place to another, therefore, considerable economy will be obtained in securing proper protection for any part of our coast line and for any harbor.

In the present war railway artillery was used for the following kinds of fire: (*a*) Fire for destruction; (*b*) fire of interdiction; (*c*) counter battery work; and (*d*) reprisal bombardment.

Fire for destruction includes the demolition of railway centers, depots, fortified works, bridges, etc. For this work high-angle or plunging fire is desirable in order that the projectiles may bury themselves in the ground before exploding, thus causing a large crater to be formed and securing the maximum amount of destruction. For this kind of fire the use of howitzers and mortars is indicated. If it is required to obtain a number of direct hits on a small target at a range of 20,000 to 25,000 meters, it would be better to use a considerable number of total rounds which can be obtained economically with guns having a long accuracy life, namely, howitzers and mortars. Beyond the range of howitzers, guns must be used. Rapid firing not being essential, the sliding type of gun mount is entirely satisfactory.

Interdiction firing includes destruction and interruption of traffic on lines of communication. It may be desirable to keep certain sections of a railway line out of commission or to shell sections of some important road over which supplies of men must move. In this case the target is usually small and therefore greater accuracy of fire is necessary. As time is required to repair the damage, intermittent shelling will suffice. Two to four well-placed shots a day are sufficient to keep a railway line out of commission. For this work, therefore, it has been the practice to use very long-range guns with a sliding type of railway mount.

Counter battery work includes the destruction of such enemy batteries as are out of range of the army artillery. The army artillery consists of guns of about 6-in. caliber and howitzers of about 9.5-in. caliber. The range is 15,000 to 18,000 meters, whereas all railway artillery should have a minimum range of about 23,000 meters and preferably 25,000 meters or more. A very wide traversing angle is essential on account of the probably wide variations in the position of the enemy batteries which must be reached quickly. An 8-in. gun is best for this class of work mounted upon a carriage similar to our 8-in. barbette, model 1918, previously described.

Reprisal bombardment requires the use of long-distance guns such as the German gun which shelled Paris. This gun was not, however, mounted upon a railway carriage. A sliding type of mount, combined with a recoil mechanism, would seem to be the proper mounting.

For use against heavy concrete fortifications a howitzer such as the 16-in. would be proper, as a smaller size would probably fail to have the desired destructive effect, but for the destruction of a railway bridge the use of a 16-in. howitzer would be very wasteful, as a direct hit from an 8-in. gun would be about equally effective for destroying the superstructure.

Lessons of the War

The value and economy of seacoast defense has been completely demonstrated in the present war. The absolute protection afforded the German coast line on the North Sea and the completely successful defense of the Dardanelles are the most striking examples. Considering the fortifications of the Dardanelles only, it is undoubtedly a fact that the coast defenses established there had a value to the Central Powers of many billions of dollars. In fact, it can hardly be contradicted that, had these fortifications been forced, the resistance of the Germans

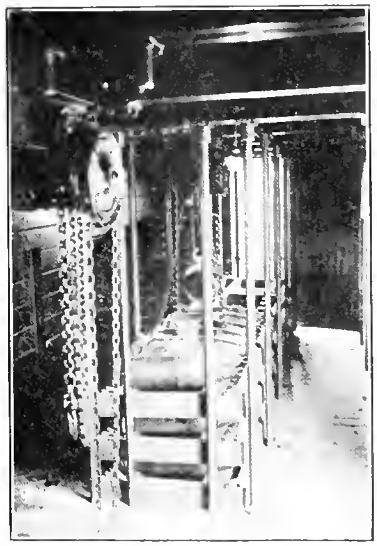

Fig. 5 Interior of Ammunition Car

would have been broken long before was actually the case. Their military value was a hundred times their actual monetary cost. It is also probable that, had the guns at the Dardanelles been mounted on railway carriages of suitable design and had comparatively inexpensive railway tracks been laid to important tactical points, it would have been almost impossible for landing parties in any force to have succeeded in effecting their object. This lesson as to the value of seacoast defenses is of the utmost importance to us, because our coast line is so extended that the cost would be considered prohibitive if adequate, fixed fortifications were to be furnished for all points whose strategic position would apparently justify such defenses.

The present state of the art of artillery design is such that guns and howitzers having a range of 22,000 meters or more are of such weight and exert such forces due to the firing of the gun that they must be mounted either on fixed carriages or on railway cars. However, in the immediate future it is evident that guns mounted upon self-propelled caterpillars will appear, and probably within the next few years railway artillery will be limited to guns of 10-in. caliber and up, and howitzers of 16-in. caliber and up. The development of this caterpillar artillery was begun by the Ordnance Department about three years ago and successful types have been built for 7.5-in. guns and for 8-in. howitzers. The next step will be the substitution of the caterpillar treads for the railroad trucks in mounts such as the 8-in. gun and 12-in. mortar.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

SUBJECTS OF THIS MONTH'S ABSTRACTS

BRIDGES

The Wilson Bridge at Lyons. On Bastille Day, July 14, 1918, was formally opened at Lyons Le Pont Wilson, so named in honor of the President of the United States. The Wilson bridge, as shown in Fig. 1, consists of four unequal elliptical arches with a short elliptical approach arch at each end and a total width between the parapets of about 66 ft. It is designed on the Séjourné system, which briefly consists of replacing the central portion of the arches regarded longitudinally by a deck of reinforced concrete, so that each span consists of two masonry arches entirely independent of each other, except in so far as they rest on the same abutments, with the intervening space filled in with the reinforced-concrete deck. Because of the conditions of the currents in the River Rhone the arches are not symmetrical in span about the center of the bridge.

For various reasons metallic centering instead of wooden was employed and each of the principal arches composed of three courses of masonry at the springings and two at the crown.

The voussoirs fit into each other after the manner of gear-wheel teeth, both in the longitudinal and in the transverse direction. The first course was laid down in eight sections supported on angle pieces, the sections being arranged symmetrically and in such a manner as not to cause the centering to suffer any deformation. The joints were filled with mortar rammed in by means of iron beetles. The filling was commenced at the highest joints, the succeeding joints being completed in succession at properly chosen intervals of time. (*The Engineer,* vol. 126, no. 3280, November 8, 1918, pp. 387-388, p figs., *dA*)

BUREAU OF STANDARDS

Abstract of Metric Manual for Soldiers. The aim of the metric manual is to give to American soldiers a grasp of the metric system which will enable them to think and work in metric units. As recommended, no tables of equivalents need be memorized. Brief tables and a vocabulary are given for reference. The units are described by actual examples likely to be encountered in military work. (Bureau of Standards Miscellaneous Publications No. 21)

The Influence of Quality of Gas and Other Factors Upon the Efficiency of Gas Mantle Lamps, R. S. McBride, W. A. Dunkley, E. C. Crittenden and A. H. Taylor. This paper describes the apparatus and methods employed and the results obtained in studying the effects of several variables such as gas pressure, gas adjustment, air adjustment, and gas quality upon the performance of various types of gas mantle lamps. Several tables and curves are given to assist in the presentation of the results. (Technologic Paper of the Bureau of Standards, No. 110)

ENGINEERING MATERIALS (See also Testing)

Rapid Recrystallization in Deformed Non-Ferrous Metals, D. Hanson. While the number of investigations on recrystallization phenomena in iron and steel is quite large, only two similar investigations on recrystallization in non-ferrous metals are mentioned by the author, namely, papers by Robin and by R. J. Anderson.

In the present experiments a device adopted by Chappell in his

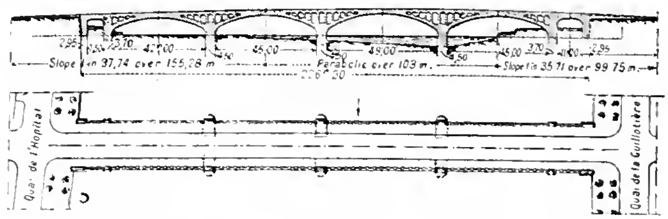

Fig. 1 Plan and Elevation of the Wilson Bridge

work on the recrystallization of iron (*Journal of the Iron and Steel Institute,* 1914, pt. 1, p. 460) has been used. This consists in cutting a test piece tapered toward the center, which, after it has been annealed, is broken in tension. In this way, with suitable tapering, varying degrees of deformation, from a maximum at the point of fracture to zero at a position between the fracture and the shoulder, are obtained. In order to obtain this the taper must be so regulated that under the breaking load of the test piece the material at the shoulder is not stressed beyond its elastic limit. The amount of taper which has proved suitable varied from metal to metal and has been determined by trial.

The paper records data secured with various metals and solid-solution alloys.

It was found in the case of aluminum and magnesium that remarkably coarse crystals had developed in the neighborhood of the shoulder where the strain was least, and that for this reason the crystal size decreased fairly regularly to the point of fracture. In the material of the shoulders which it is assumed had not been strained or in which the strain had been too slight for recrystallization to take place, the original small crystallization of the an-

nealed test piece was found, the change from coarse to fine crystals being quite abrupt.

Zinc, lead and copper exhibited essentially similar behavior. In the case of zinc, a thin sheet 0.04 in. thick was first annealed at 150 deg. cent. for half an hour, and after straining the two halves were annealed, one at 150 deg. cent. for 30 min., and the other at 300 deg. cent. for 5 min. In the case of the 150 deg. cent. annealing, recrystallization proceeded for a distance of approximately 3/4 in. from the fracture; when annealed at 300 deg. cent .for only 5 min., recrystallization occurred right up to the shoulder, and the grain size which was developed was considerable. In this case, in which the times of annealing at high and low temperature are in the reverse order to those used for aluminum, the same observation was made that, speaking generally, crystals of approximately the same size were produced in corresponding positions in the test pieces, i.e., at positions of equal deformation. The only marked effect of an increase in annealing temperature had been to extend the range of recrystallization toward the less deformed end of the specimen.

Solid-solution alloys have shown phenomena essentially similar to those of pure metals. A copper-zinc-aluminum alloy has shown appreciably the same recrystallization as pure aluminum and so has 70:30 brass. The results described in this paper suggest that the following law of annealing is probably applicable to all strained metals and solid solutions:

For every degree of deformation there is a critical recrystallization temperature at which crystal growth is extremely rapid, and the size of the crystals produced by this rapid growth is the greater the smaller the amount of deformation preceding such annealing. The rate of increase in size of the newly formed crystals with prolonged time and increased temperature of annealing is small compared with their rate of growth at the critical temperature. (Paper submitted to the Institute of Metals, on November 11, 1918, abstracted through *Engineering*, vol. 106, no. 2754, October 11, 1918, pp. 403-404, 3 figs., *ct*.t)

The Porosity and Volume Changes of Clay Firebrick at Furnace Temperatures, Geo. A. Loomis. Paper published by permission of the Director, U. S. Bureau of Standards, and reporting an investigation undertaken in order to study the fundamental properties of clay firebricks by a comparison of their changes in porosity and volume upon heating to different temperatures with the results of a specific load test and with the so-called "softening points."

The determination of these softening points is generally considered a reliable indication of the refractoriness of the material. Actually, however, it is apt to be misleading, for bricks with the higher softening point sometimes fail to withstand practical conditions of load and temperatures; while the silicious bricks low in flux with a comparatively low softening point generally stand up well under heavy loads at fairly high temperatures. Further, the softening-point determination is misleading in the case of bricks made from a coarse mixture of very refractory non-plastic clay with an inferior bond clay.

The load tests are used by the Bureau of Standards and the ball tests first applied in the laboratories of the Carnegie Steel Company are also discussed, and the methods of carrying out the tests in the present investigation discussed. The following is a summary of the results as given by the author.

1 Brick which are capable of withstanding a pressure of 40 lb. per sq. in. at 1350 deg. cent. generally show slight changes in volume or in porosity when burned at temperatures up to 1425 deg.

2 The greater number of the brick which failed to pass the load tests show rather marked changes in volume or in porosity at some temperature below 1425 deg. cent.

3 Brick which show distinct overburning by pronounced expansion at temperatures below 1400 deg. cent. invariably fail in the load test. The adoption of a definite limit for the permissible expansion within the given temperature range is particularly important for detecting inferior clay refractories. The limit for expansion should be lower than that for allowable contraction.

4 The changes in volume and in porosity of brick burned at some temperature between 1350 deg. cent. and 1425 deg. cent. serve, in a measure, as a criterion of their ability to pass the load test.

5 Most of the brick which show a porosity decrease not exceeding 5 per cent and a volume change not exceeding 3 per cent (approximately 1 per cent in linear dimensions), when burned at 1400 deg. cent. will pass the load test.

6 Brick which show a decrease in porosity exceeding 5 per cent or an expansion of contraction in excess of 3 per cent by volume (1 per cent in length) at 1400 deg. cent. failed to pass the load test in nearly all cases.

7 The use of limiting porosity and volume changes for clay firebrick burned at 1400 deg. cent. would serve as a means of eliminating from consideration a large number of brick which fail in the load tests.

8 Brick which fail in the load test—due to failure in the bond—may not show marked changes in volume or porosity in burning but often show very low cold-crushing strength.

9 No definite relationship seems to exist between the softening point of a firebrick and its ability to withstand load at high temperatures. However, all brick which softened below cone 28, whether silicious in character or not, failed completely in the load test. It seems advisable, then, to specify cone 28 as the minimum softening point for any clay firebrick. It is probable that brick containing less than 65 per cent SiO_2 should have a minimum softening point of cone 31. (*Journal of the American Ceramic Society*, vol. 1, no. 6, June 1918, pp. 384-404, 2 figs., *e*.t)

FOUNDRY

The Integrity of the Malleable Casting, Enrique Toucede. The writer claims that without present knowledge of the art of malleable casting, it is possible to produce regularly such a character of hard iron that when annealed it will yield metal of superior strength and ductility. If failure occurred, it was because the foundryman did not make sure at all times that castings were invariably sound throughout.

In proof of this, the writer offers figures showing the combined monthly average ultimate strength and elongation of some 32 different companies for a period of three months based on data from many hundreds of tests. These figures show a remarkable uniformity of the average values over that period.

It is claimed that lack of solidity, when it occurs, is mainly due to failure on the part of the founder to recognize the fact that in castings of disproportionate sections so frequently used in malleable-iron work the thinner sections solidifying more quickly than thicker ones would draw the metal from the still fluid parts before they, in turn, were able to secure their full share of metal from the risers.

The use of chills was tried to equalize cooling and while it did not always do it sufficiently to make heavy parts perfectly sound, it did serve to lessen the shrink and drive it from a place where its presence was fatal to a locality much less harmful. Nevertheless, the writer considers that the use of chills has been harmful as it kept the founder from discovering the real cure for this trouble. (Paper presented at the American Foundrymen's Convention, at Milwaukee, October 7-11, 1918, abstracted through *The Iron Age*, vol. 102, no. 20, November 14, 1918, pp. 1204-1205, *p*)

Casting Under Pressure. Description of a new process for forming castings of non-ferrous alloys. This process consists in pouring the molten alloys into metal molds and forming or congealing the castings under pressure. The castings are made in a specially constructed automatic machine by which several hundred are turned out per hour. The alloys used so far have been one of 60 per cent copper, 40 per cent zinc, with a trace of lead, and another alloy of 86.5 per cent aluminum, 12 per cent zinc, 1.5 per cent copper. A large number of fuse bodies for shrapnel have also been produced of an alloy of 80 per cent aluminum and 20 per cent zinc made to British specifications which call for an elongation of 7 per cent in 2 in. Tests have shown that this alloy actually possesses an elongation in excess of 14 per cent in 2 in. with a tensile strength of 41,440 lb. per sq. in. and an elastic limit of 30,400 lb.

In this process an alloy has been made and used consisting of aluminum, copper and iron with a low coefficient of expansion. The introduction of iron into this alloy promises to make it possible to produce very large aluminum pistons for high-power aircraft engines without running into the usual difficulties caused by the high coefficient of expansion of aluminum.

A similar alloy appears to have been used in the framework of a German Zeppelin machine. (*The Iron Age*, vol. 102, no. 19, November 7, 1918, p. 1138, *d*)

FUELS AND FIRING

SAVING COAL IN BOILER PLANTS, Henry Kreisinger. Mem.Am. Soc.M.E. A paper containing suggestions as to what can be done in the boiler room to save coal and intended especially for medium-size plants, which, as a rule, have less efficient equipment and management than large and modern plants. The paper is of particular interest, but is not suitable for abstracting. (*U. S. Bureau of Mines Technical Paper* 205, *p*)

HEATING AND VENTILATION

HOW TO IMPROVE THE HOT-AIR FURNACE is the title of Technical Paper 208, just issued by the Bureau of Mines, Department of the Interior, the author being Charles Whiting Baker.

O. P. Hood, chief mechanical engineer of the bureau, in reviewing Mr. Baker's paper, says: "Hot-air furnaces for house heating are used in such great numbers, especially the smaller sizes, that one would expect a considerable literature on the subject of

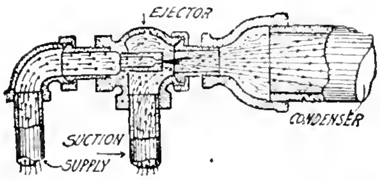

FIG. 2 STEAM EJECTOR USED IN THE MOLINE VACUUM VAPOR HEATING SYSTEM

their economical design, installation, and operation. As a matter of fact, there is much less to be found on this subject than on steam and hot-water house-heating equipment, largely because of the difficulty of measuring the output from a hot-air furnace. The quantity of heat absorbed from the fire by either hot-water or steam systems is rather easily measured by accepted methods, but it has proved a problem of some difficulty to accurately measure the quantity of heat absorbed by the hot-air furnace. Hence the problem has been much less attractive as a laboratory investigation than problems having to do with steam or hot-water apparatus. There is, however, a real need for a larger body of information about the performance of hot-air furnace installations than is now available.

"Mr. Baker's article shows how interesting such problems can be, how really worth while it is for a good engineer to give them careful and ingenious attention. The Bureau of Mines is glad to print such material, which will not only help many users of hot-air furnaces but will also tend to stimulate investigation in this fertile field.

"During the war the husbanding of fuel supplies must be a matter of vital concern to the country. The Bureau of Mines, in its efforts to bring about greater efficiency in the use of fuels, has paid much attention to the improvement of house-heating and boiler-plant equipment and methods of operating them, and has published a number of reports on the subject. Among these are Technical Paper 80, Hand-Firing Soft Coal under Power-Plant Boilers; Technical Paper 97, Saving Coal in Heating Houses; Technical Paper 199, Five Ways of Saving Coal in Heating Houses; and Technical Paper 205, Saving Coal in Boiler Plants.

"This paper, which was presented by the author before the American Society of Heating and Ventilating Engineers, at Buffalo, N. Y., in June, 1918, points out certain defects in existing types of hot-air heating plants, and suggests a number of improvements in construction and operation that will add to the comfort of the householder and lessen his coal bills. Moreover, the paper deals with a subject that, in spite of its wide interest, has received relatively little attention and is not treated in any other publication of this bureau. For these reasons, and for the further reason that general observation of the suggestions would effect an important saving in fuel, the paper is published by the Bureau of Mines."

Copies of this paper may be obtained free of charge by addressing the Director of the Bureau of Mines, Washington, D. C.

MOLINE SYSTEM OF VACUUM VAPOR HEATING. This system belongs to the class of those in which the steam pressure ordinarily carried is practically at atmosphere or slightly below, or in which the returns are open to the atmosphere and where no pump or other positive mechanical device is employed to pull back the returns. It is characterized by the use of a lock-shield globe valve on the return end of each radiator and the use of an ejector fitting to produce a pull on the return lines of greater intensity than can be secured by simply opening the return line to the atmosphere, or by connecting the air-vent line to the chimney and employing the chimney draft.

The steam ejector, which is the main characteristic feature of the system, is operated by the steam or air pressure at the end of the supply main, just before it drops down to enter the boiler return.

Fig. 2 shows how the steam or air under pressure in the steam line flows out through the nozzle of the ejector fitting, creating, by its velocity, a section around the jet, and employing this section to draw the air from the return lines to discharge the mixture into the condenser.

The article describes also the air trap used with this system. (*Heating and Ventilating Magazine*, vol. 15, no. 11, November 1918, sixth installment of a serial article, pp. 44-46. 5 figs., *d*)

INTERNAL-COMBUSTION ENGINEERING

Fuel-Injection Valves for Diesel Engines

FUEL-INJECTION VALVES IN CONSTANT-PRESSURE ENGINES, W. Stremme. Data for the calculation of needles and springs in needle valves for engines of the constant-pressure type. According to Fig. 3, the injection air which atomizes and injects the fuel enters through the atomizing chamber R. In the circular cross-section of this chamber the air acquires a certain velocity. Further, the dimensions of this air-injection chamber determine the amount of air available for the fuel injection at the instant of opening of the valve orifice. In the same chamber R are located the atomizing disks P, and the size and number of orifices in these disks determine the velocity of the air available for its intermixing with the fuel. Each atomizing disk measures the velocity of flow of the fuel-air mixture, and the more disks there are in the chamber R, the slower does the injection occur. No improvement in fuel injection can be secured by any very large increase in the number of atomizing disks.

The atomizing disks are followed by the atomizing cone, the purpose of which is likewise to give the fuel-air mixture a certain velocity of flow. The cone K regulates the valve opening and closing. The nozzle orifice S must also have a certain cross-section, since it is here that the atomization of the fuel properly takes place. All the cross-sections in the path of the flow of air inside of the fuel valve must be several times greater than the section of the nozzle. In Fig. 4, ad shows the developed cam governing the fuel-valve motion. This line ad likewise determines the duration of opening of the fuel valve. During the opening of the valve, throttling occurs over ab, due to the action of the cone on the needle; it also occurs over cd during the closing of the valve.

From point b on, the cross-sections opened up by the needle are larger than the nozzle cross-sections, and hence the curvature of the cam determined by the height h_1 has no influence on the variation of the fuel flow. An increase in the nozzle opening

displaces the point b toward b_1 and the point c toward c_1. Therefore, the amount of injection air can be increased by using a steeper shape of the cam, ab_2 and c_2d, and can be reduced by giving the cam a gentler slope, as ab_3 and c_3d. The amount of injection air may also be increased with the same cam shape by increasing the size of the holes in the atomizing disks, and contrariwise, may be reduced by reducing their size. The variation of the nozzle orifice has the greatest influence on the amount of injected air.

However, the rate of air injection can also be effectively varied

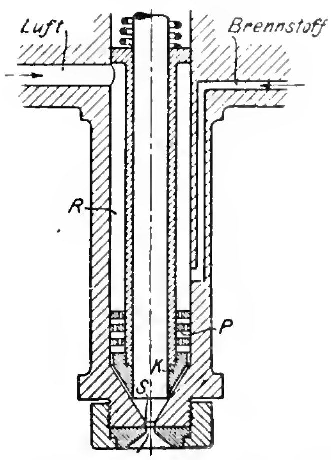

FIG. 3 DIAGRAM OF FUEL-INJECTION VALVE IN A CONSTANT-PRESSURE-TYPE ENGINE

(*Luft*, Air; *Brennstoff*, Fuel)

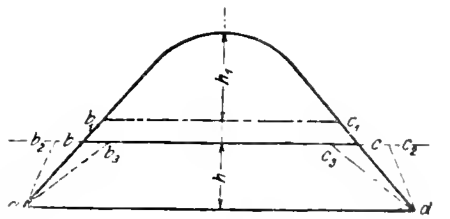

FIG. 4 DEVELOPED PROJECTION OF A CAM FOR THE VALVE SHOWN IN FIG. 3

by changing the injection pressure. The amount of air Q flowing through the nozzle is determined by the equation $Q = fv$, where f is the cross-section of the nozzle and v the velocity of the flow of air. This velocity of flow of air can be calculated from the following formula:

$$v = \sqrt{\frac{2gH}{\gamma}} = K\sqrt{H}$$

where H is the gage pressure of the injection air.

This method is used for reducing the output of stationary and marine engines in order to secure a combustion free of carbon deposits through a reduction of the injection air pressure.

If in the last equation the magnitude of $\sqrt{H}$ remains unaltered, the equation $f = Q/v$ can also be written in the form $f = cQ$. Q is here the amount of the fuel-air mixture which passes per unit of time through the cross-section f. In order to produce a good atomization of a given amount of fuel, q, it is necessary to apply a certain definite amount of injected air. Hence, Q = Fuel + Air of Injection, or $Q = q + mq = q\,(1 + m)$, and the equation $F = cQ$ becomes $F = c\,(1 + m)\,q = c_1q$. For a nozzle cross-section δ we have the equation $\delta = K_0\sqrt{q}$. Instead of the fuel consumption per second, we may use the engine output N_i. This alters the coefficient in the above equation, which becomes $\delta = K\sqrt{N_i}$.

Since the value of K is affected by many independent variables, it is impossible to give it a numerical value which would be good for all cases. Rather the exact value of K should be determined for each engine. The standardization of the fuel nozzle can be carried out only in so far as to determine for each engine the dimensions of the fuel nozzle, which, in as far as possible, corresponds in every respect to the performances desired. The value of K can be determined from the equation $\delta = K\sqrt{N_i}$. The knowledge of the value of K permits to determine the characteristics of the nozzle for engines of the same type, and this again determines the dimensions of all other parts. Fig. 5 shows the relations of the values based on the above described standardization, with reference, however, to existing engine types.

The abscissæ of Fig. 5 show the outputs of individual cylinders, and the ordinates, the values of cross-sections of the main atomizing devices referred to the nozzle cross-sections, calculated from the above formula. Curve I is the curve of the valve space. Curve II gives the relative values of the needle cross-section and Curve III the values of the cross-sections of the holes of the atomizing plates. The cross-sections of the cone passages are also roughly taken into consideration. Curve IV gives the values of the sections of the passages of the needle cone.

Engines which have been built according to such standardized proceedings need not, in the opinion of the writer, be tested out at the factory. Besides, such a standard proceeding gives at once the main dimensions of the fuel valve for engines to be built. (Original article published in *Zeitschrift des Vereines deutscher

LUBRICATION

Oil Consumption in Steam-Engine Lubrication

STEAM-ENGINE LUBRICATION, Hilliger. According to Schmid, in steam engines properly cared for the hourly consumption of cylinder oil in grams may be taken to be equal to $L = 1.6D_nsn$, where D_n is the diameter of the low-pressure cylinder in meters, s the stroke in meters and n the speed in r.p.m. Weiss offered for the same case the equation $L = 2D_hn$, where D_h is the diameter of the high-pressure cylinder. If the two equations were correct they should have given approximately equal values for similar engines. Table 1, however, which gives the oil consumption per hour calculated for several engines in accordance with both of these equations, shows that the values thus obtained do not agree very well with each other. Apparently, the equations cited above do not give the correct minimum values of oil consumption.

Hilliger has carried out tests with a view to determining the oil consumption of a steam engine. These tests were made on a locomobile built by the Wolf Company of Magdeburg. The cylinders were lubricated by a pressure pump which delivered 12 grams of oil per hour to the cylinders at 230 r.p.m. of the engine. The cylinders were 130 mm. (5.1 in.) bore and 260 mm. (10.2 in.) stroke. In each test the cylinder received a definite amount of oil. The lubrication was then stopped and the variation of mechanical efficiency with time determined. In order to establish accurately the quality of the cylinder lubrication it was necessary to determine the mechanical efficiency with precision. For the determination of the effective output of the locomobile, a load was used consisting of a belt-driven direct-current generator.

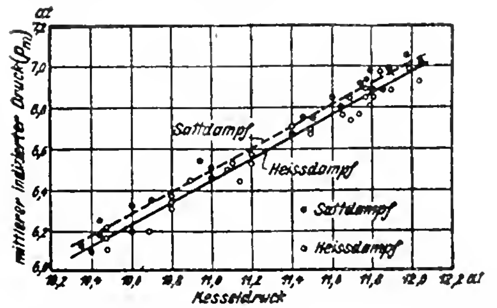

FIG. 6 RELATION BETWEEN AVERAGE INDICATED PRESSURE AND BOILER PRESSURE FOR SUPERHEATED AND SATURATED STEAM

(Ordinates: Average indicated pressure (p_m); abscissae: Boiler pressure; *Sattdampf*, Saturated steam; *Heissdampf*, Superheated steam; *at*, pressure in atmospheres.)

The indicated output of the engine was determined from the equation $N_i = 0.015 p_m n$, where p_m is the average indicated pressure in atmospheres. In the course of the tests it was found impossible to determine p_m from the indicator diagrams with sufficient precision. Because of this the governor was so adjusted that up to a speed of 245 r.p.m. it could not affect the valve gear. By plotting diagrams of equal cut-off but with variable admission pressure, it can be shown that the average indicated pressure

320 and 500	470	109	40	68
200	360	120	14	48

varies approximately with the boiler pressure. Since the expansion line of superheated steam is different from that of saturated steam, the relation between the average indicated pressure and the boiler pressure has to be determined separately for the two conditions of steam, and Fig. 6 shows this relation for both cases.

In the tests with the boiler pressure maintained at the same level of 11.8 atmos., the electrical output was so manipulated that in all tests the speed of rotation was 230 r.p.m. In this way the indicated output was maintained the same in all tests and the effective output can then be calculated from the equation—

$$N_e = \frac{\text{voltage} \times \text{current}}{736 \eta_{el} \eta_R}$$

where η_{el} is the electrical efficiency of the generator and η_R the efficiency of the belt drive, which latter may be taken to be equal to 0.95. The mechanical efficiency is then $\eta_{mech} = \frac{N_e}{N_i}$. The three types of oil which were used with tests, with their respective characteristics, are described in Table 2.

Fig. 7 graphically represents the data of tests with the German superheated-steam oil used with saturated steam. With regular lubrication the curve of efficiency runs about 95 per cent. With

(Ordinates, Mechanical efficiency, per cent; abscissae, Time; *Zylinderschmierung 12 g/St*, Cylinder lubrication 12 grams per hour; *Zylinderschmierung abgestellt*, oil feed to cylinder discontinued; *Versuch 1*, Test No. 1; *50 g Oel*, 50 grams of oil supplied to cylinder.)

the supply of oil discontinued, the curve stays for a while at 95 per cent and then begins to fall off rapidly. When the efficiency has fallen five or six per cent, 50 grams (1.75 oz.) of oil are forced into the cylinder, which produces a considerable improvement in mechanical efficiency.

In tests with superheated steam the same German superheated-

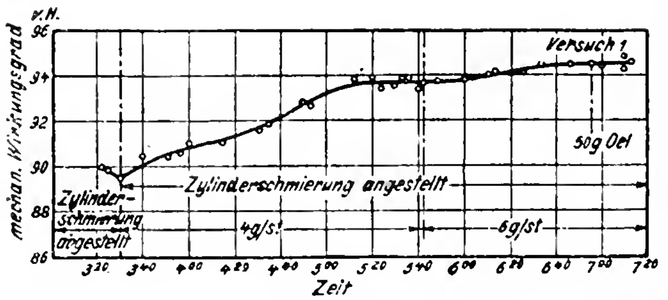

FIG. 9 EFFICIENCY CURVE WITH VARIABLE OIL FEED, SUPERHEATED STEAM

(Ordinates: Mechanical efficiency per cent; Abscissae: Time; *Zylinderschmierung abgestellt*, Oil feed to cylinder discontinued; *Zylinderschmierung angestellt*, Cylinder lubrication resumed; *g/St*, grams per hour; *Versuch 1*, Test No. 1; *50 g Oel*, 50 grams of oil supplied to cylinder.)

steam oil was used. In these tests also the efficiency did not vary during the time that oil was regularly fed to the cylinders, but fell off very soon after the supply of it was discontinued, even though at a rate not as rapid as in the case of saturated steam. Fig. 8 represents graphically the data of these tests. In order to secure a clearer insight into what has taken place with cylinder lubrication, it was necessary also to determine the minimum amount of oil with which the engine could be uniformly operated. This may be defined as the amount of oil with which the mechanical efficiency will be maintained at its highest point. Fig. 9 shows

the plot of the efficiency curve with variable oil feed. The reciprocal values of the amount of oil necessary to maintain efficient lubrication may be considered as index figures for the given oil.

Fig. 10 shows the manner in which the specific oil consumption varies with the indicated output. The values of oil consumption have been derived from marine engines of similar construction in which the oil consumption has been carefully noted. From this figure it appears that with increase in output the specific oil consumption decreases very materially, but at high outputs there is no longer any noticeable decrease in oil consumption. In the foregoing figures the oil used in lubricating the auxiliary engines,

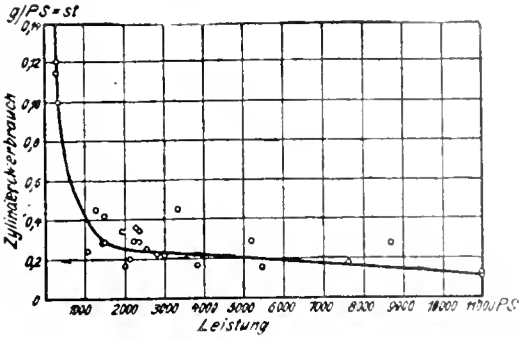

FIG. 10 VARIATION OF SPECIFIC OIL CONSUMPTION WITH INDICATED OUTPUT, MARINE ENGINES.

(Ordinates: Oil Consumption per Cylinder, in Grams per Hp-Hour; Abscissae: Cylinder Output in Hp.)

amounting to from 8 to 10 per cent of the total consumption, has also been taken into consideration.

Stationary engines of the vertical type show a higher oil consumption than marine engines. The straight-flow engines, of which quite a number have been built in recent years, show, in general, a peculiar behavior, in that the specific oil consumption decreases with the increase of output along an approximately straight-line law. At the same time, as is evident from Fig. 11, they have a very

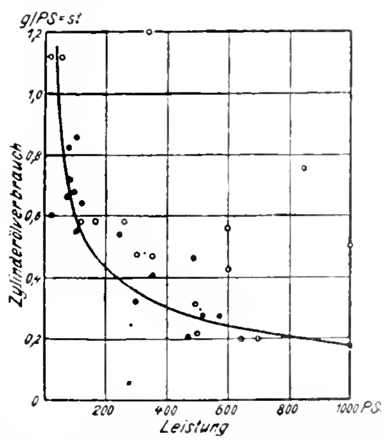

FIG. 11 VARIATION OF SPECIFIC OIL CONSUMPTION WITH INDICATED OUTPUT OF VARIOUS TYPES OF STEAM ENGINES

(Ordinates: Oil Consumption per Cylinder in Grams per Hp-Hour; Abscissae: Cylinder Output in Hp.)

high general oil consumption, due, apparently, to the large piston surface, and to the arrangement of exhaust slots. The piston in passing over the exhaust slots scatters through them a certain amount of lubricating oil which is in this way lost for further lubrication.

For horizontal stationary engines the law governing oil consumption is difficult to establish because of the variety of types of such engines. Fig. 12 gives an idea as to the values of consumption found with this type of engine. These figures give the total oil consumption; that is, in addition to the cylinder lubrication, also that used for the lubrication of the stuffing boxes on the piston rods, valve rods and connecting rods.

Finally, Fig. 13 gives a résumé of the cylinder-oil consumptions of various types of steam engines. (*Zeitschrift des Vereines deutscher Ingenieure,* 1918, Nos. 14, 15, 16, abstracted through *Dingler's polytechnisches Journal,* vol. 333, no. 14, July 13, 1918, pp. 122-124, 8 figs., *e*)

MACHINE DESIGN

ON THE THERMODYNAMICS OF SPRINGS, H. Bock (*Zeits. Instrumentenk,* 38, pp. 109-115, July, 1918). The thermal processes which ensue during the extension of elastic bodies have long been known, but although of outstanding significance for engineers, yet the data have been seldom employed by them, probably owing to the form in which they have usually been expressed. The author now attempts by means of an analogy with the p-v diagram to give a simple process whose application to the theory of springs leads to the possibility of expressing numerically the

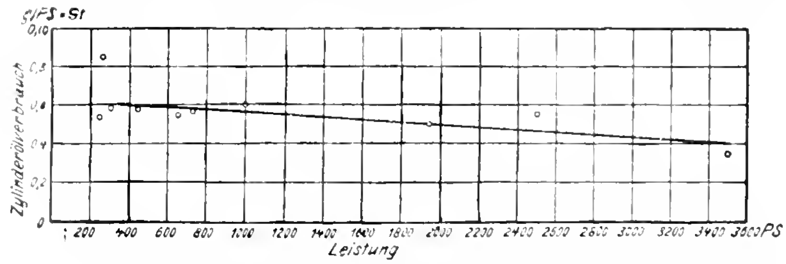

FIG. 12 VARIATION OF SPECIFIC OIL CONSUMPTION WITH INDICATED OUTPUT, HORIZONTAL STATIONARY ENGINES.

(Ordinates: Oil Consumption per Cylinder in Grams per Hp-Hour; Abscissae: Cylinder Output in Hp.)

elastic after-effect. It is shown that perfectly elastic bodies must be attended by such after-effects—a fact of considerable importance for fine springs such as chronometer spirals. The various limitations assumed are first given, and then the equation of state of a long bar is derived corresponding to that for a gas. The σ-l diagram is next plotted, where l is the length and σ the tension along this direction. Following this comes a discussion of the internal energy of the bar, together with the determination of c_1 (the specific heat at constant length corresponding to that of constant volume in the gas equation). The adiabatics of the bar is next examined, and the expression for the entropy obtained. The theoretical results are then applied to determine the energy loss when the bar is made into a spring, and the special case of energy loss in the watch spring concludes the paper. (*Science Abstracts,* Section A—Physics, vol. 21, pt. 10, no. 250, October 31, 1918, p. 436, *t*)

MACHINE SHOP

INSPECTION OF STEEL ARC WELDS, O. S. Escholz. It is stated that the four factors which determine the physical characteristics of the metallic-electrode arc welds are fusion, slag content, porosity and crystal structure.

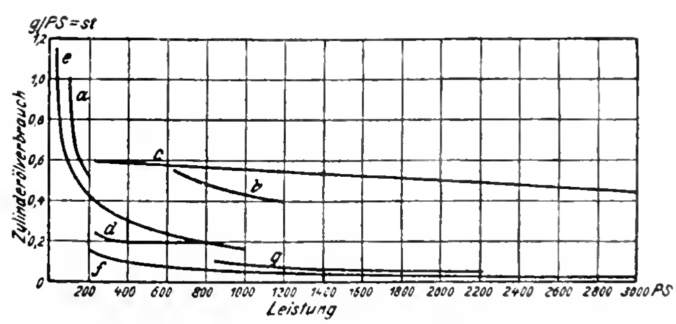

FIG. 13 VARIATION OF CYLINDER-OIL CONSUMPTION WITH INDICATED OUTPUT, STRAIGHT-FLOW ENGINES

(Ordinates: Oil Consumption per Cylinder in Grams per Hp-Hour; Abscissae: Cylinder Output in Hp.)

The writer enumerates various methods for determining the quality of the weld. The most reliable indication of the soundness of the weld is offered by the penetration tests. In the testing of small samples excellent results are made possible by the use

of X-rays, but it is difficult to manipulate with the present apparatus in large-scale production.

In penetration tests, liquids, such as kerosene, give practically as good results as gases and are much easier to apply. Because of its low volatility and high-surface tension, kerosene sprayed on a welded surface is rapidly drawn into any capillaries produced by incomplete fusion between deposited metal and weld scarf or between succeeding deposits, slag inclusions, etc. It penetrates through the weld and shows the existence of a weak structure by a stain on the emerging side.

Electric test methods by which the homogeneity of welds is determined are still in the evolutionary stages. The tests recommended are visual examination, chipping and penetration tests.

As regards the arc weld itself, the cardinal steps in its analysis are preparation of weld, electrode selection, arc-current adjustment, arc-length maintenance and heat treatment.

In this connection the writer points out that a great many companies have attempted welding with too low an arc current and the result has been a poorly fused deposit. This is due

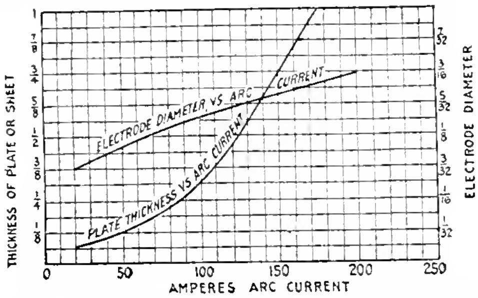

Fig. 14 Values of Arc Current to Be Used for a Given Thickness of Steel Plate and of Electrode Diameter for a Given Arc Current

largely to the overheating characteristics of most electrode holders which lead the operator to believe that the current used is in excess of the amount needed.

The approximate values of arc current to be used for a given thickness of mild-steel plate, as well as the electrode diameter for a given arc current, may be taken from the curves of Fig. 14. The variation in the strength of 1-in.-sq. welded joints as the welding current is increased is shown in Fig. 15.

In the opinion of the writer the heat treatment of a completed weld is not a necessity particularly if it has been preheated for

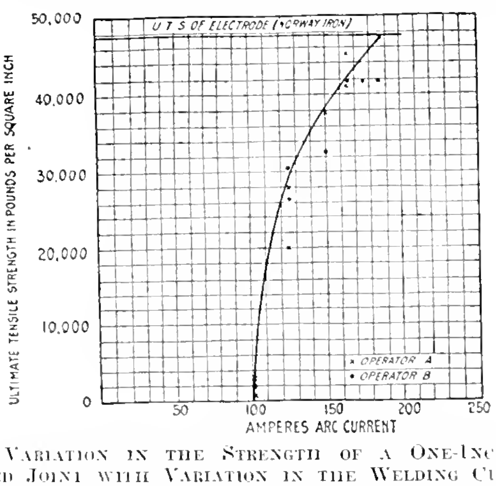

Fig. 15 Variation in the Strength of a One-Inch-Square Welded Joint with Variation in the Welding Current

preparation and then subjected to partial annealing. A uniform annealing of the structure is desirable even in the welding of the small sections of alloy and high-carbon steels, if it is to be machined or subjected to heavy vibratory stresses. (*Iron Age*, vol. 102, no. 23, December 5, 1918, pp. 1390-1391, 2 figs., *p*)

Machine Shop for Gas-Producer Work. Description of the new plant and gas producer of the Smith Gas Engineering Company at Morain City, a suburb of Dayton, Ohio.

The design of the generator is such that the heavy elements (shell and lining) are stationary, freeing the operating mechanism from severe strains. Grates and clinker bars operate through compressed-air cylinders. Coal is charged without admission of air, the stokers being driven by a variable-speed electric motor and each capable of independent starting or stopping by engagement or disengagement of its driving pawl.

The gas from the generator goes through a downcomer to a primary cooler, then to a gas pump and tar extractor. The tar-laden gas in passing through the extractor comes in contact with the diaphragm of spun glass. Friction against this material charges it with static electricity, which causes fine particles in the tar fog to cling together until they are of sufficient size to drop out of the current by gravity. This spun glass, by the way, had to be imported from Austria before the war, but is now produced in this country. (*Iron Age*, vol. 102, no. 23, December 5, 1918, pp. 1373-1378, 14 figs., *d*)

MARINE ENGINEERING

Application of Buoyancy Boxes to the S. S. "Lucia" for the U. S. Shipping Board, W. T. Donnelly, Mem.Am.Soc.M.E. Brief description of a method for providing internal buoyancy for ships or boats, with numerous plates illustrating the construction used on the S. S. *Lucia*.

At an early stage in the work it was found that ordinary methods of construction for the buoyancy boxes would not do and new ways of construction had to be developed to make the boxes capable of withstanding pressure and absolutely watertight. Every box was tested by air pressure and floated in a tank before being placed in the vessel.

Approximately 12,000 boxes, divided about equally between buoyancy boxes for ship, or cargo, were required. As regards the question of reduction of cargo space due to the presence of the boxes, it is claimed that this reduction corresponds only to the weight of the buoyancy boxes and has no necessary bearing upon the room they occupy.

The paper presents in considerable detail the buoyancy and stability calculations for the S. S. *Lucia*, together with calculations as to what would happen in case of various parts of the ship being opened by a torpedo explosion. In considering the problems of longitudinal stability, the writer uses the section-modulus method instead of the metacentric-height method such as was first employed by Professor Hovgaard, and the difference between these two is carefully pointed out.

From the mechanical engineer's point of view the details of flotation boxes are, of course, of considerable interest. Because of this Fig. 16 is reproduced giving the details of three types of boxes found necessary.

The boxes have been so standardized that a uniform size of lumber can be used for all types. The boxes actually used were made of ordinary lumber and galvanized sheet iron and the quantity of the latter was quite considerable. (Paper before the Society of Naval Architects and Marine Engineers, read at the Annual Meeting, in Philadelphia, November 14-15, 1918, 14 pp. and 10 plates of drawings, abstracted from advance copy, *dA*)

MECHANICS

Vibration of Tall Chimneys

Wind Pressure on Tall Chimneys. Data of an investigation by Professor Omori (Japan) on the movements which wind pressure induces in the top of a tall chimney. The interest of this investigation lies in the fact that it furnishes the means of determining the degree of stability possessed by tall columns having an oscillation period of more than two seconds.

The chimney was erected at Saganoseki by the Weber Chimney Company of Chicago and is made of reinforced concrete. Its height is 550 ft. above the foundation pier. It stands on a hard paleozoic formation of a very low seismic movement. The base is about 450 ft. above sea level, which brings the top to a height of about 1000 ft. where it must experience a much greater wind velocity than that registered at the surface. The external diameter

is 27 ft. 5 in. at the top and 42 ft. 8 in. at the bottom. The wall thickness is 7 in. at the top and 29.5 in. at the bottom.

The article describes the method of observation used. The oscillations of the top of the shaft as registered by the automatic recorder are reproduced on a much reduced scale in Fig. 17. The upper diagram shows the motion transverse to the direction of the wind at the time of greatest velocity during a storm (December 26) when a Robinson anemometer recorded a wind velocity of 35 meters per second (114.8 ft. per sec.). The lower curve indicates the motion parallel to the direction of wind about one-half hour later. The difference in amplitude is very pronounced. The observers on the top of the column were sensible of the greater oscillation in the direction of the component at right angles to the wind's direction than that parallel to the wind. Professor Omori attributes this peculiar behavior to the pressure period of the transverse oscillation is very slightly larger than that of the parallel, and if this difference be real it may be traceable to the position of the flue causing the shaft to oscillate more easily in the transversal direction, but the evidence is not conclusive.

The diagram of Fig. 17 shows a succession of small and large vibrations at intervals of about 10 or 12 sec., the maximum motion never being continuous for any considerable length of time. In this respect the column behaved as a huge anemometer and the duration of alternating large and small groups of vibrations may be regarded as indicating a comparatively rhythmical succession of periods of violent winds alternating with the times of cessation.

The article presents briefly data of similar observations on two other chimneys in Japan, each having a height of 100 ft.

The main conclusion reached is that wind pressure on a tall

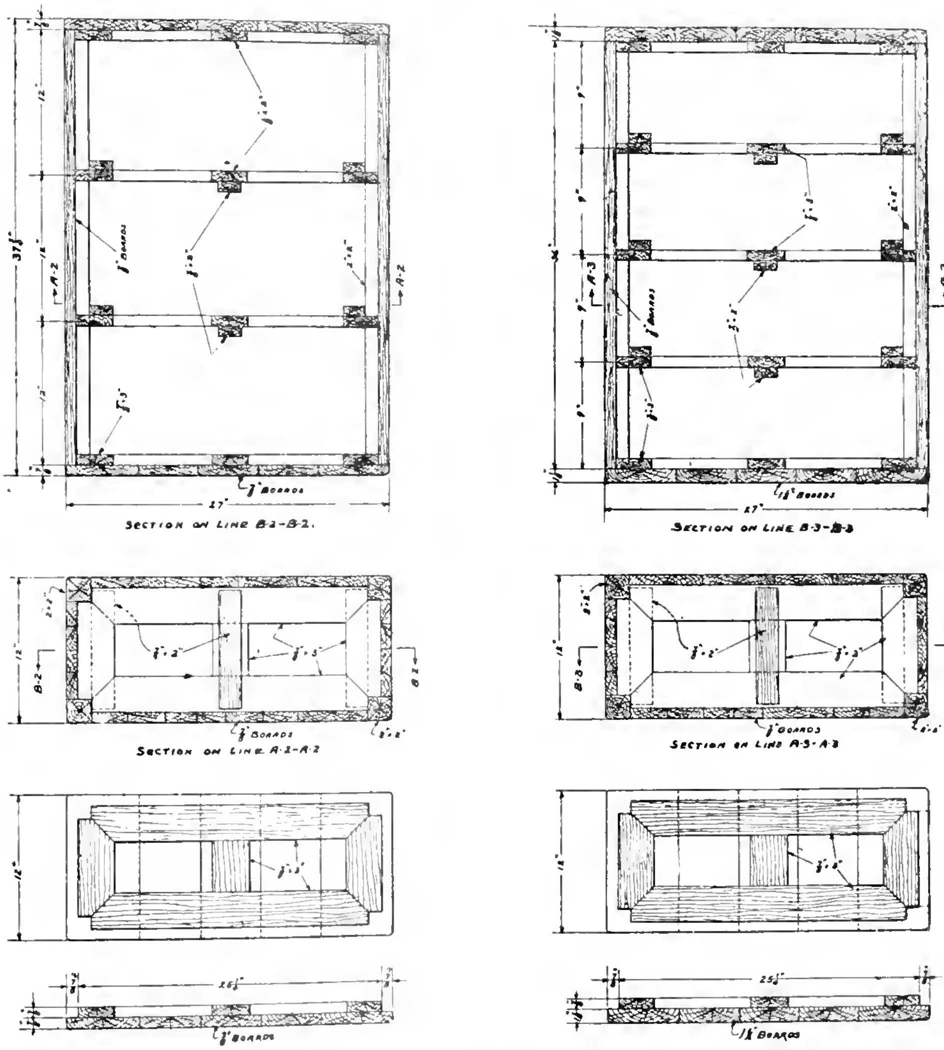

FIG. 16 DETAILS OF FLOTATION BOXES USED IN THE DONNELLY METHOD OF INCREASING BUOYANCY OF SHIPS

of the wind bending the column and rendering it more difficult for it to oscillate. The writer remarks, in this connection, that since the angle through which the column is bent (supposing it to move as one piece) is only about 30 seconds of arc, a greater variation in the time of vibration could be expected than is shown in the diagram if this damping action of the wind were real. But the constancy of periods in winds of all strengths is as remarkable as the variation in amplitudes.

Table 3 and Table 4 show the vibrations of the column in directions normal and parallel to that of the wind. One of the important facts indicated by these figures is the rapid increase in amplitude with the increase of the wind's velocity. It appears that the simple law according to which pressure varies as the square of the velocity does not hold here at all. The period of oscillation in either direction does not vary with the amplitude, at least within the range of the present experiment. The mean chimney can entail consequences as disastrous as those due to seismic motions, even in countries where such occurrences are frequent and severe. The observed motion of the Saganoseki chimney indicated a maximum acceleration of 565 mm. per sec. per sec., whereas on the occasion of the destructive Tokio earthquake of June 20, 1894, the intensity was 444 mm. per sec. per sec. Should the wind velocity reach 50 meters (164 ft.) per sec. the vibration would acquire an acceleration of more than 1000 mm. per sec. per sec. Only very near the epicenter of an earthquake is such an intensity to be anticipated. Again, a reinforced-concrete chimney of less than 200 ft. in height must be regarded as a "short column," and in such structures it is desirable to reduce the height of the center of gravity as much as possible. On the other hand, the 550-ft. Saganoseki chimney, and still more a 1000-ft. chimney already projected, must be regarded as "tall columns" that are seismically weakest, not at the base, but at

about two-thirds of the height. In the usual chimney construction the center of gravity of the whole structure is situated at about one-third of the height, while that of the upper third portion alone is nearly at the middle of its height, causing the shaft to be comparatively weak near the top. Professor Omori recommends such a distribution of the material that the center of gravity

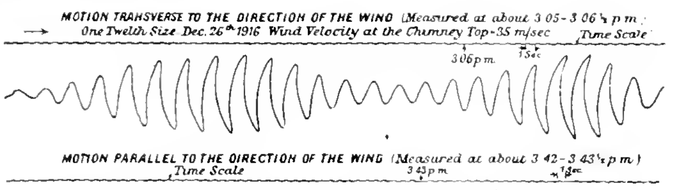

Fig. 17 Motion of a Tall Chimney Transverse (Top) and Parallel (Bottom) to the Direction of the Wind

should be at one-fourth the height of the whole structure, as well as for the upper portion alone. In such a case the chimney would possess uniform strength against an earthquake shock. But if the center of gravity of the upper third part be about the middle of this section, the effect would be to weaken the shaft at the place where the seismic motion would be most effective. On Vibrations of Beams of Variable Cross-Section, N. W. Akimoff, Mem.Am.Soc.M.E. The paper presents a review of the fundamental investigations of the best-known problems of vibratory motion of rods and proposes to revive the interest of research engineers in the method of Ritz, published about ten years ago, but comparatively unknown in many engineering circles.

The paper is mainly of a mathematical character and as such is not suitable for abstracting. The writer considers the method proposed for finding periods of vibrating bars by Professor Morrow. The principle of this method is as follows: By assuming an equation which completely satisfies the end conditions, both the vibration curve and the period of the fundamental oscillation are found to any required degree of accuracy. This method is especially valuable in finding the periods of vibration when the density and flexural rigidity of the bar are variable from point to point in its length. The author applies the Morrow method to the consideration of the cases of a clamped-free bar, free-free bar and various cases of clamped-free bars of variable breadth and depth.

From this the author proceeds to a brief reference to Professor Slocum's formula for the shearing deflection of beams of arbitrary cross-section, either variable or constant, and then goes on to the general discussion of the principles of the calculus of variations and its application to dynamical problems which serves as a basis for the presentation of the Ritz method.

The Ritz method is applied in this case to the problem of finding the fundamental tone of free vibrations of vessels, the hull of a vessel being here considered as a free-free bar of variable cross-section irregularly loaded. (Paper read at the General Meeting of the Society of Naval Architects and Marine Engineers, in Philadelphia, November 14-15, 1918, abstracted from advance copy, 30 pp., *mA*)

Thickness of Wall for Tubes Under Pressure, M. Suwalski (*Zeits. Vereines Deutsch. Ing.* 62. pp. 551-552, Aug. 17, 1918). Gives formulæ for the thickness of tube required to withstand given pressures, using the simple formula $pd = 2sk_z$, where p is the pressure in kg./cm.², d is the inner diameter, s the thickness of the tube, and k_z the tensile strength in kg./cm.². This simple equation is modified by putting $k = A(1 + d/200)$, A being a constant depending on the value of p. (*Science Abstracts*, Section A—Physics, vol. 21, pt. 10, no. 250, October 21, 1918, p. 404, *t*)

METAL-WORKING TOOLS

Machine Tools for Neville Island Gun Plant. Two new types of single-apparatus shell-turning and boring machines are being built for the Neville Island Gun Plant of the United States Steel Corporation.

The machines are practically identical as to bed and headstock. The bed is 29.9 ft. long, 5.25 ft. wide, and the turning machine has a 39-in. swing. The bed is a solid piece integral with the head. The machines are designed to turn 12-in., 14-in., 16-in. and 18-in. shells, with provision made for 20-in. shells if that size is desired.

The auxiliary carriage is provided with two tools, one for turning the straight portion and the other the curved surface at the nose at the same operation. Back of the carriage, rigidly fixed to the bed, is a forming attachment with two cam slots, one straight and one slightly diagonal controlling the tool turning the straight portion, and the other curved and engaging the tool for the curved portion at two points. As the carriage travels it carries the cutting tools that have the curved surface, being held at right angles to the surface at all times, thus eliminating any necessity for the shells being turned in steps. The action of this curved cam slot is to carry the tool through an arc as though it were operated on a pivot. (*Iron Age*, vol. 102, no. 18, October 31, 1918, pp. 1071-1074, 5 figs., *d*. Also in *Iron Trade Review*, vol. 63, no. 18, October 31, 1918, pp. 1012-1013, 2 figs., *d*)

MUNITIONS (See Metal-Working Tools)

POWER GENERATION

Wind Power for Electricity Generation, P. Schubach (*Helios*, 24. no. 17. 1918, *Elektrot. u. Maschinenbau*, 36. p. 385, Aug. 25, 1918, Abstract). The author calls attention to the rapid multiplication of wind-power installations in Denmark, and considers that their employment will become even more general in country districts as a result of the war.

Wind-velocity observations at Lindenberg Observatory have shown that in low-lying districts at sea level the mean wind velocity is 4.7 m. per sec.; at 500 m. this rises to 8.9 m. per sec., and at 1000 and 1500 m. to 9.2 and 9.4 m. per sec. respectively. The energy available, N, for the wind motor can be calculated from the formula $N = YFv^2\ (150\,g)$, where F is the projection of the total wing surface in square meters, V the wind velocity in meters per second, Y the weight of 1 m.³ of air, and g the acceleration due to gravity.

Table 5 gives the relation between size and output of wind motors for wind velocities of 5 and 7 m. per sec.

Reference is made to the wind motors of the G. R. Herzog Saxon Steel Wind-Motor Co., of Dresden. In these the dynamo is driven by means of gearing and countershaft. Auxiliary wind

wheels serve for rotating the main wheel according to the wind's direction and for adjusting to the wind's intensity. The main wheel is mounted on a wooden or iron tower in such a way that

TABLE 5 RELATION BETWEEN THE SIZE AND OUTPUT OF WIND MOTORS

Wheel Diam. in Meters	*F* in Sq. Meters	Hp. Developed 5 m. per sec. wind velocity	Hp. at 7 m. per sec. wind velocity
2.5	2.9	0.16	0.6
3.5	5.2	0.3	1.0
4	7.2	0.5	1.5
5	11	1.0	2.5
6	16.7	1.5	4
7	22.4	2.0	5
8	28.8	2.5	6
10	44	4	8
12	65	6	14

the lower edge of the wheel clears by 2 or 3 m. any obstacles there may be to the wind over a radius of 200-300 m. The irregular operation of such a motor necessitates the use of a storage battery to work in parallel with the dynamo, and this battery should be capable of supplying two days' current requirements. The cost of operation is given as 4 to 7 pfennigs per hp.-hour, or 120 to 210 shillings per hp.-year, including interest, amortization, and attendance.

Two suitable regulators are then described: these appear to be of the usual type, namely, an automatic cutout operating when the speed falls below a certain value, and a voltage-regulating centrifugal governor which operates the field resistance of the dynamo. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, pt. 10, no. 250, October 31, 1918, p. 363, *g*)

POWER PLANTS

Economic Operation of Steam Turbo-Electric Stations, C. T. Hirshfeld and C. L. Karr, Members Am.Soc.M.E. Discussion of economies which may be effected in the use of fuel through the application of proper operating methods at large turbo-generator power plants.

It is stated that in a single plant with a given load curve the fuel economy is dependent upon the following three independent factors, namely:

1 The method used in distributing the load between the main units available
2 The methods used in the boiler room for producing the steam required
3 The methods used for obtaining auxiliary power for house service.

In connection with the matter of distribution of load between main units, the paper points out that most of the steam-driven turbo-generators built in this country have steam characteristics of the general type shown in Fig. 18. The total steam consumption increases approximately according to a straight-line law until a point is reached where the rate of increase becomes more rapid, causing the plot of total steam consumption to curve upward as shown in the figure.

The steam pressure, superheat and vacuum or back pressure all have marked effects on the steam consumption or water rate of steam turbines, which latter also varies from time to time for a given unit under given conditions of pressure, superheat and vacuum. This supplementary variation may be due to deposits on blading, wear of blading, variation of clearances, settlements in bearings, and other uncontrollable factors.

It is therefore advisable to test each machine through its entire range of load once in every eight weeks at stations operating continuously. Tests at about five or six equally spaced loadings generally suffice to determine the water-rate curves with the required degree of accuracy.

As regards the method of determining load distribution, it is stated that the distribution of load between units so as to yield the minimum water rate for any given station load may be determined mathematically, but this method has not yet been reduced to a form easily understood and applied. Hence a less exact but easy-of-application cut-and-try method is described.

As regards the operation of auxiliaries, the writers arrive at the following conclusions:

1 The smallest thermal cost for auxiliary power is incurred when generated by steam with complete absorption of the exhaust in the feedwater
2 The greatest possible part of all of the auxiliary energy required can be obtained in this way when the steam drives used with the auxiliaries have the greatest possible thermal efficiency
3 Auxiliary power in excess of that obtainable with exhaust steam absorption can be procured from the main generators in electrical form at a lower thermal cost than in any other way.

To these conclusions may now be added two commonly known facts:

1 The increasing price of fuel is leading more central stations to the use of economizers
2 The greatest saving is effected with economizers when the water supplied them is at the lowest permissible temperature. This value is probably somewhere between 120 deg. and 150 deg. fahr., depending upon the types of economizer used and the care with which it is operated.

The writers show that large errors can be made in the original design of supplying auxiliary power. It is also possible to make costly errors in operation. To illustrate: Assume that in a certain station, operating at normal day load, the total amount of power used for auxiliaries and for house service of all kinds amounts to

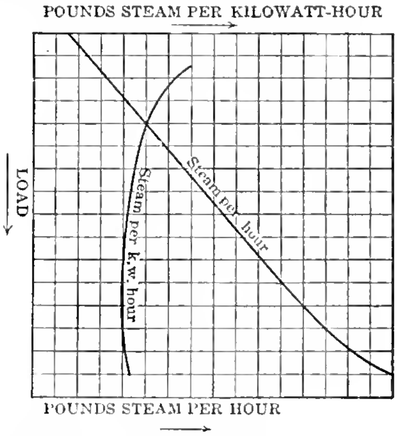

Fig. 18 Steam-Consumption Curves for Turbo-Generator

10 per cent of that sent out. This is a figure that should not be exceeded but is often equaled. Under these conditions, for every 1000 kw-hr. sent out of the station it is necessary to produce 100 kw-hr. for the operation of auxiliaries, station lights, etc.

If it be assumed that the main units are capable of producing a kilowatt-hour for 20,000 thermal units in fuel fired it is possible to show the decidedly weighty influence of the thermal cost of auxiliary power.

It has been shown that auxiliary power may cost anywhere between about 4500 and 200,000 thermal units, depending on the method used. At 4500, the auxiliary power would cost about $4500 \times 100 = 450{,}000$ thermal units in the assumed case. This would be equal to about 2.25 per cent of $20{,}000 \times 1000 = 20{,}000{,}000$ thermal units required by the main units. On the other hand, if the auxiliary power costs 200,000 units per kw-hr. the total would be $200{,}000 \times 100 = 20{,}000{,}000$, or exactly the same as that required by the main units.

With all auxiliary power taken electrically from efficient main units the cost would probably be at least 23,000 units per kw-hr. This would give a cost in the assumed case equal to $23{,}000 \times 100 = 2{,}300{,}000$, or about 11.5 per cent of that required by the main units for the generation of power leaving the station. RAILROAD ENGINEERING

Dimensions of Air Passages in Locomotive Grates

Heat Losses in Locomotives. Data of tests on steam locomotives carried out by the Prussian Railroad Administration in 1913. This series of articles started in 1917, but the issues previous to that from which this abstract is made are not available in this country at the present time.

The present section describes tests made to determine the losses through conduction, radiation and smokestack. These losses are usually assumed to be on the average 5 per cent. The values of line 7 in Table 6 have been obtained by planimeter summation of areas. From these average values have been derived coefficients of evaporation calculated in the usual manner.

The most interesting part of this particular series of tests was that through which it was intended to determine the relation between the free grate area to the total grate area and its influence on the rate of combustion. To do this it was necessary to determine the pressure which should be used with various dimensions of the free grate area to force through the uncovered part of the grate the amount of air necessary for good combustion. The average excess air is assumed to amount to 30 per cent. If one kilogram of coal consumed contained, for example, 0.72 kg. of carbon, 0.05 kg. of hydrogen and 0.12 kg. of oxygen, then with an average consumption of 450 kg. per sq. meter per hour and a grate area (of the test locomotive) of 2.3 sq. meters, the total amount of air necessary per second is

$$L = \frac{100\,(\frac{8}{3}\times 0.72 + 8 \times (0.05 - 0.12)\,450 \times 2.3 \times 1.3}{23 \times 1.29 \times 3600} = 2.78 \text{ cu. m.}$$

This shows that if the free grate passages constituted 23.3 per cent of the total grate area, the velocity of air flowing through the grate slots is

$$v_1 = \frac{2.78}{0.23 \times 2.3} = 5.3 \text{ m. per sec.}$$

which corresponds to a pressure of

$$h_1 = \frac{5.3^2 \times 1000}{2 \times 9.81 \times 775} = 1.85 \text{ mm. water}$$

For a free grate area of 45 per cent, the velocity becomes

$$v_2 = \frac{2.78}{0.45 \times 2.3} = 2.7 \text{ m. per sec.}$$

and the pressure

$$h_2 = \frac{2.7^2 \times 1000}{2 \times 9.81 \times 775} = 0.48 \text{ mm. water}$$

From line 11 in Table 6, it is found that the total pressure difference between the ashbox and the firebox is with upper Silesian coal between 30 and 40 mm. of water and with Westphalian coal 45 to 60 mm. The free grate area can, therefore, within the above-named limits, have only a slight influence on the total difference in pressure between the ashbox and the firebox, even under the assumption that the values of pressure calculated above may be raised somewhat through the existing subdivision of the total free cross-section of the grate.

It appears, therefore, that with the definite action of the air injector and with the definite height of the coal bed, the dimensions of the free grate area may vary within fairly wide limits without materially affecting the amount of air driven in, and hence the quality of combustion.

The lower value of the free grate usable seems to lie at about 20 per cent. If it be decreased further there appears on one hand an enhanced resistance which increases with the square of the velocity of the air; and on the other hand, the distribution of the air becomes defective which leads to the formation of slags. (*Annalen für Gewerbe und Bauwesen*, vol. 82, no. 1 973, January 1, 1918, pp. 1-4, serial article. *c*)

Influence of Internal Fissures in Rails

Rails and the Accident on the Long Island Railroad. On April 15, 1918, there was a derailment of a troop train on the Long Island Railroad, near Central Islip, New York.

Investigation indicated that the cause of the accident was due

to the failure of two rails in which a number of transverse fissures were present. The rails were 80 lb. in weight, A. S. C. E. section, bessemer steel, rolled by the Lackawanna Iron and Steel Company. Each rail displayed a number of transverse fissures, some of which were visible and one accidentally discovered through nicking which happened to be done in the vicinity of a transverse fissure which had not reached the periphery of the head.

The appearance of the fissures is shown by microphotographs, two of these fissures having increased in size to such an extent that they had reached the periphery of the head on the gage side. Other fissures have not become exposed externally. The rails when polished and etched were shown to be structurally very unsound and this lack in uniformity had also been observed in machining the rail sections. Portions of the cross-section were spongy; other parts were hard and machined with difficulty.

From information acquired it appears that at the time when these rails were rolled, or about 1897, the Lackawanna Iron and Steel Company used horizontal heating furnaces, soaking pits not having then been introduced.

The internal stresses in the two rails were measured, and the results are shown in the original report by means of diagrams.

It is interesting to note that from outward appearances the rails were sound looking and showed that little wear had taken place. The shapes of the heads showed but little distortion, yet within them destructive transverse fissures had developed. It is not known over what interval of time these transverse fissures had been in existence. They carried, however, the lighter traffic of the railroad for a period of time without known examples of transverse fissures having appeared. War activities increased the traffic from seven to ten times in the amount of tonnage with a considerable increase in the weight of the equipment, conditions which not unlikely contributed toward the formation of transverse fissures and accelerated their development. The investigation has, however, clearly established that the rails were of very poor metal, a metal, moreover, which appears to have been defective even at the time the rails were rolled.

The interesting features of the report are data of an investigation on the development of fissures in these rails and the distribution of internal stresses in the various parts of the cross-section.

The report comes to the conclusion that from information thus far obtained it appears that rails are strained higher than other classes of engineering materials. Another section of the report tells of annealing tests on a number of hot-forged bars of rail steel and other grades. In these annealing processes were used cooling by an air blast, quenching in oil and quenching in water. The tests with rail steel were fairly consistent, but tests on low-carbon steel and chrome-nickel steel furnished results of a paradoxical nature. The chrome-nickel bars conformed in behavior to the rail steel, while the low-carbon steel displayed opposite characteristics and contracted in length when heated and quenched, whether oil or water were used as the quenching medium.

It is claimed that a distinction may properly be made between approximate cause of the formation of transverse fissures and features which may promote or retard their inception and progress. In any event, transverse fissures are shown to be a progressive type of fracture. (Report of the Chief of the Bureau of Safety, Covering the Investigation of an Accident Which Occurred on the Long Island Railroad, near Central Islip, New York, on April 15, 1918, *Interstate Commerce Commission*, August 5, 1918. 45 pp., 70 figs., *cpA*)

STEAM ENGINEERING

A Large Turbo-Alternator Unit

45,000-KW. CROSS-COMPOUND STEAM TURBINE. Description of the turbo-generator unit recently put in service in the Brunot's Island Power Station of the Duquesne Light Company at Pittsburgh, Pa.

Essentially the unit is not radially different from others of the same type; the principle of cross-compounding in steam turbines not being new any longer. A new feature, however, is the installation of a device for cutting out one side of the turbine if for any reason its immediate removal from service becomes necessary; this device may also operate automatically. In this way a 45,000-kw. machine has the flexibility of a 22,500-kw. unit.

Each turbo-generator rotor is supported in its own bearings so that four bearings are required for each element. The bearings are self-aligned and are supported on spherical keys with sheet-metal liners of different thicknesses for horizontal or vertical adjustment. Oil for lubrication is admitted to the bearing casing at the bottom, the sides of the bearing being eccentrically relieved for a space of about 35 deg. above and below the center line to within an inch of the end, to provide a reservoir of oil along each side. The turbine is free to expand axially by sliding on its supports, which are applied directly below the horizontal joints, the turbine itself being anchored to the inboard generator pedestal.

The low-pressure rotor is composed of a central hollow drum rigidly secured to the spindle ends, on each of which are pressed two blade rings or disks carrying the low-pressure blades. The maximum mean velocity of the blades is only 515 ft. per sec., which brings the rotating stresses at 20 per cent overload to less than 20,000 lb. per sq. in., and makes it possible to use a good grade of cast steel in the blade rings. This is safer and better than using special-grade steels which are not only hard to get even in normal times, but may carry undetected flaws and are more

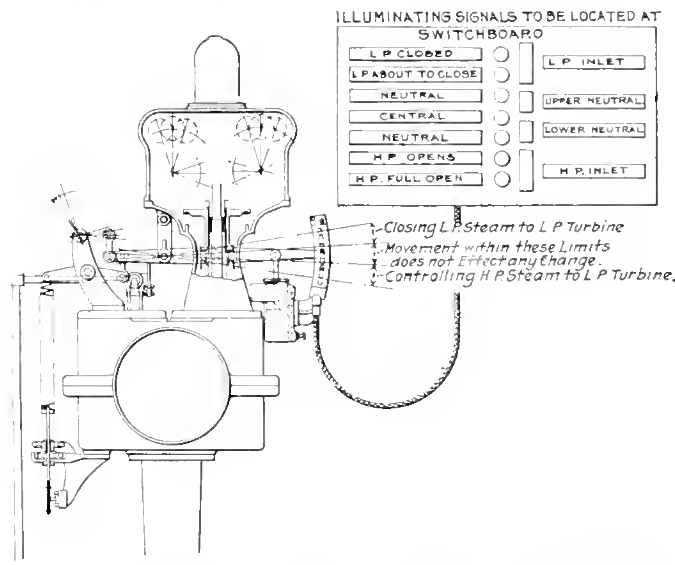

FIG. 19 LOW-PRESSURE TURBINE GOVERNOR ON THE 45,000-KW. CROSS-COMPOUND STEAM TURBINE AT DUQUESNE

subject to trouble from improper heat treatment. Phosphor-bronze blades are used except in the last three rows of the spindle, which are drop-forged steel.

Each turbine is provided with an overspeed-stop governor which will shut off steam in that unit in case the speed should rise 10 per cent above normal. Each unit also has a speed-control governor. The one on the high-pressure turbine which normally controls the steam supplied to the whole system is of the customary form. The governor on the low-pressure side, Fig. 19, has some special features.

The low-pressure governor should not be called upon to act except in the case of an emergency, and in order that the switchboard operator may be aware of the state of things, a system of signal lamps is arranged to show the position of the governor in the neutral zone. By changing the tension of the speed-changer spring, the governor may be kept in its middle position so that a normal fluctuation of frequency will not cause the governor to function. The spring on the low-pressure governor is designed to give a total speed range of 12 per cent, which is divided up as follows: Starting from the central position, if the speed rises 4 per cent, the governor is on the verge of tripping the low-pressure inlet valve. With a further rise of less than 1 per cent the valve will be tripped shut, one more per cent travel being provided for clearance. From the central position downward, should the speed decrease 2 per cent, the high-pressure valve will begin to open,

and will be full open after 3 per cent more decrease. Another 1 per cent is also provided at this end for overtravel.

The signal lamps in the switchboard gallery, Fig. 19, are controlled from the low-pressure governor by a system of contacts operated by an extension on the governor lever. As the governor moves between its inner and outer position this lever travels across the contacts, registering its position on the illuminated sign.

To review the system briefly: If the circuit breaker on the low-pressure element should open due to a short-circuit, the turbine will speed up and close the steam inlet from the high-pressure cylinders. The high-pressure turbine will continue to run, carrying its load and exhausting to atmosphere, while the low-pressure turbine, with its source of steam cut off, will fall in speed until reaching 2 per cent below normal, when the governor valve will admit high-pressure steam. In the meantime, if the line has been cleared the unit may be synchronized and reconnected to the bus bars, the gate valve opened, and the low-pressure cylinder receive its steam as before. If the low-pressure turbine for similar reasons should overspeed 10 per cent and the automatic stop operate, it will result in the automatic closing of the high- and low-pressure steam inlets, and the opening of the circuit breaker, and this half of the turbine will be entirely shut down. The high-pressure element, however, will continue to run non-condensing and carrying its load as usual. (*The Electric Journal*, vol. 15, no. 11, November 1918, pp. 435-441, 7 figs., *d*)

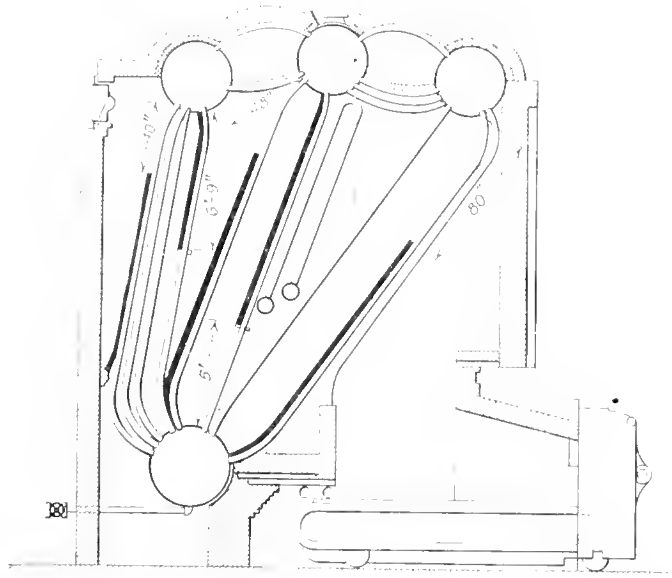

FIG. 20 BAFFLES WHICH GAVE EXCESSIVE FLUE-GAS TEMPERATURES AT 150 PER CENT RATING

DEVELOPMENT OF STEAM-BOILER BAFFLES, Albert A. Straub. Descriptions of several types of baffles with illustrations and brief criticisms. In the same articles are presented data of tests made on a type of baffle shown in Fig. 20 as applied to a Stirling boiler. Tests made with this arrangement gave excessive flue-gas temperatures at 150 per cent rating, which led to a change in location of the baffles and closing up of baffle openings as shown in Fig. 21. With this arrangement of baffles the capacity of the unit was not decreased, but the temperature of the escaping gases was decreased 60 deg. fahr. at 150 per cent rating and 70 deg. fahr. at 210 per cent rating with a corresponding effect in efficiency.

A further change was made in this baffle arrangement after the tests had been completed by placing the first baffle back of the second row of tubes and extending the last baffle down 24 in. toward the mid-drum. This change reduced the temperature of escaping gases 50 deg. fahr. at the higher ratings.

The ratio of efficiency to capacity for the unit with baffling shown in Fig. 21 is given by the curve of Fig. 22. Several other interesting tests are reported in considerable detail in the original article. (*Power*, vol. 48, no. 19, November 5, 1918, pp. 656-659, 9 figs., *de*)

AVOIDING DISTORTION IN TURBINE OPERATION, Webster Tallmadge, Mem.Am.Soc.M.E. Brief discussion of the causes of distortion and suggestions for practical methods so to operate the turbine as to avoid this occurrence. Valuable suggestions are given as to turbine and steampipe installation so designed to insure safety in this respect. (*Power*, vol. 48, no. 22, November 26, 1918, pp. 762-765, 8 figs., *p*)

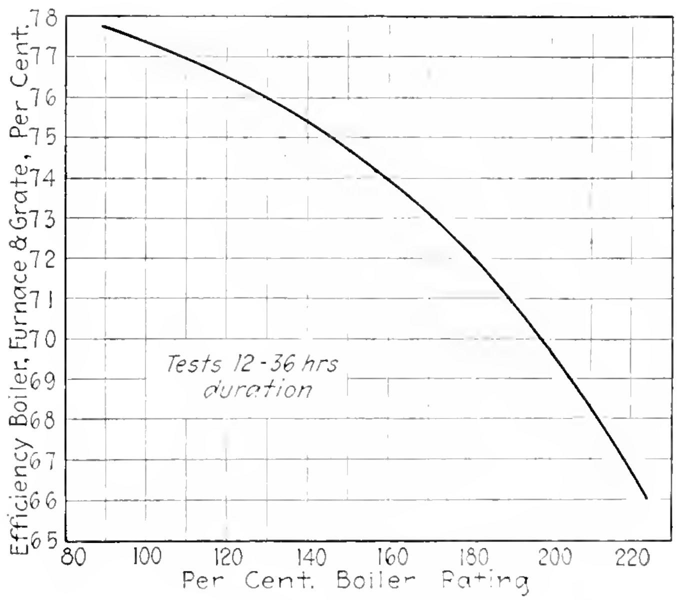

FIG. 22 RATIO OF EFFICIENCY TO CAPACITY OF BOILER BAFFLE AS SHOWN IN FIG. 21

TESTING

PHYSICAL TESTS OF ROLLED SHELL STEEL, James J. Mahon. The physical variations in rolled steel are sometimes greater than might be expected from chemical variation. This variation in physical properties is not found to enter any particular bar of the rolled ingot and at times is much more than the variation usually found between the inner and outer portions of the cross-section of the ingot. It would appear that this might be attributed to the direct rolling of the steel after a prolonged heating which leads to precipitation of the ferrite during the heating process. An investigation was made during which tests and photomicrographs were taken from a great many heats of steel and it was found that

the precipitation of ferrite in some heats was greater than in others. Heats of steel which failed on preliminary tests but in which the precipitation of ferrite was not excessive usually passed the physical requirements after forging.

Although the reheating of the material was too rapid to be classed as a heat-treating operation, it answered the purpose for such steel as was not badly affected. It was found that the ferrite was reabsorbed at a temperature of 1450 deg. fahr., but the quality of the steel was not impaired when the temperature was carried as high as 1750 deg. fahr. before cooling.

It is suggested that the weakness in the metal caused by the precipitation of ferrite might be eliminated by a double rolling operation consisting of breaking down the ingots into blooms and then reheating them before the final rolling.

FIG. 23 PHOTOMICROGRAPHS OF SHELL STEEL FROM TEST BAR TAKEN FROM A DIRECT ROLLED SECTION

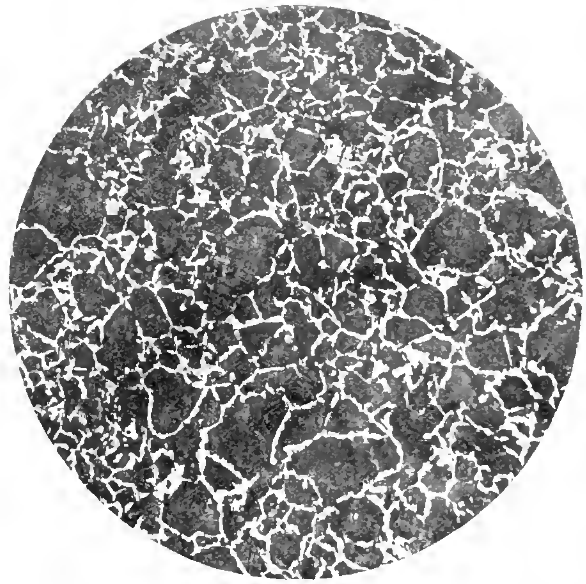

FIG. 24 PHOTOMICROGRAPHS OF SHELL STEEL FROM TEST BAR TAKEN FROM A SECTION AFTER HEAT TREATMENT AT 1450 DEG. FAHR.

In Fig. 23 the structure of the bar rolled direct from the ingot shows the weakness in steel produced by direct rolling or forging after a prolonged heating. Fig. 24 shows the structure after heat treatment at 1450 deg. fahr. Steel in the condition shown in Fig. 23 might to some extent be compared to a metal made up of alternate layers of various thicknesses of soft and hard material welded together.

From this investigation it appears that the extent of inherent weakness in such metal can be determined by the percentage of elongation to the tensile strength, and if so, the data as to percentage of yield to elongation should be a part of every specification where a good quality of steel is desired. (*The Iron Age*, vol. 102, no. 18, October 31, 1918, pp. 1082-1083, 2 figs., *e*)

VARIA

WAR SECRETS. During the visit of the Inter-Allied Petroleum Council in the latter part of November, it was revealed for the first time that a pipe line had been laid across the neck of Scotland, through which oil fuel could be pumped in a cold state at the rate of about 100 tons per hour. The pipe follows the course of the Clyde and Forth Canala, with terminals at Old Kilpatrick and at Grangemouth. At one end 16 huge tanks have been constructed with a holding capacity of a thousand tons, and at the other end the oil falls into reservoirs easily accessible to the fleet from its base at Rosyth. The pipe is 8 in. in diameter and there are two intermediate pumping stations. This is only one of the few secrets revealed since the signing of the armistice.

Another such secret is that the U. S. Navy Department proposes to use argon to inflate gas bags in balloons. This item has been taken from an official statement issued by the Navy Department. It should be added, however, that it is by no means clear what it means, since the specific gravity of argon is so close to that of air that it does not appear obvious how any lifting power can be secured by its use.

In connection with aeronautics, another important and well-kept secret has recently been revealed, and that is that the U. S. Navy has developed what is, perhaps, the largest seaplane type known. In a recent test this seaplane officially marked as NC-1 made a flight with 50 men on board.

This is the first American tri-motored seaplane, being propelled by three Liberty motors that develop a maximum of 1200 hp., giving it a cruising speed of 80 miles an hour. The flying weight of the machine is 22,000 lb., while the weight of the seaplane itself, unloaded and without a crew, is 13,000 lb.

An idea of the size of the big seaplane is shown by the fact that the wing spread is 126 ft., the breadth of the wing 12 ft., and the gap between wings 12 ft.

Recently the NC-1 made the trip from Rockaway to Washington, about 350 miles, in 5 hours and 20 minutes. The flight from Washington to Hampton Roads, 150 miles, was covered in 2 hours and 15 minutes, and the trip from Hampton Roads to New York, 300 miles, took 4 hours and 20 minutes.

Also a further development is revealed by the following statement, authorized by the War Department:

On October 15 Chauffeur R. W. Bottriell, of the 145th Air Squadron, jumped successfully with a parachute from an aeroplane at Kelly Field, San Antonio, Texas. The aeroplane was at an altitude of 4800 ft., nearly a mile high, when the jump was made. There was a strong wind blowing from the north, but Chauffeur Bottriell judged his distances nicely and landed safely in the main landing field. The pilot of the aeroplane stalled the machine slightly just before the jump was made, banking to the right so as to get the tail out of the way of the parachute when Bottriell jumped over the side. A large American flag attached to the parachute during the drop was flying during the descent.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

REVISION OF THE A. S. M. E. BOILER CODE

SECOND only in importance to the completion of the original edition of the Boiler Code, is the work of revision of the Code that has been in progress for the past two years and is now completed. The edition of 1918, which has been revised to incorporate the interpretations that have been rendered by the Boiler Code Committee during the past four years in which the Code has been operative, and also to add provisions for new types of boiler construction as a result of the development of the art, renders the work of the Boiler Code Committee a very comprehensive review of boiler practice in this country, as well as in the Canadian provinces. Its scope has been extended to cover certain additional forms of boiler construction, which were not previously referred to, and it is the belief of the Boiler Code Committee that the Code as printed in the Edition of 1918 is the most complete and exact manual of American boiler practice that has ever been produced.

Like the work involved in the completion of the original edition of the Code early in 1915, the completion of the revision work prior to the publication of the Edition of 1918, has involved an enormous amount of investigative and research work and has demanded immense sacrifices by the individual members of the Committee in the formulation of the changes in the rules. Throughout the past year, both the Committee and the Executive Committee to the Boiler Code Committee have devoted innumerable conferences to the prosecution of the revision work and every detail of the revision has been handled with the greatest possible care in order to make certain that they were presented with the best possible judgment of the various interests involved and that they might not under any circumstances bring hardship to any branch of the industry through any possibility of misinterpretation.

The revision work was begun late in 1916, when, after the widely advertised public hearings that were held on December 8 and 9 following the Annual Meeting of that year, large numbers of boiler manufacturers, users and experts came before the Committee to recommend preferred revisions in the rules, and it has continued uninterruptedly since that time with the idea of developing the proposed modifications in time for the report thereupon at the time of the following meeting. Such, however, were the obstacles encountered in arriving at complete agreement with the various other associations and organizations interested, that it was not until late in 1918 that it was possible to approach completion. The revisions of the Power Boiler section of the Code (Part I, Section I) were completed and reported to the Council of the Society at its meeting of September 20, 1918, and there approved; the revisions of the Heating Boiler section were not, however, completed for reference to the Council until its meeting of December 3, 1918, whereupon the revisions were finally approved and the printing of the new edition ordered.

The arrangement of the revised edition of the Code (Edition of 1918) is exactly the same as that of the original edition, consisting of Part I, applying to new installations, and Part II, to existing installations. Part I is further divided into Section I, applying to power boilers, and Section II, applying to heating boilers. The rules are then followed by an Appendix which embraces explanatory notes and recommendations relative to boiler construction and repairs. While the paging of the new edition has been altered to provide for the materially increased volume of the rules as revised, the subjects and the arrangement of the paragraphs have been left unaltered throughout the book in order that references to paragraphs might remain uniform throughout for the greater convenience; this also has the advantage of requiring no alterations to the paragraph numbers in the index, so that the indexing to the original edition will apply equally well to the paragraph numbers of the new edition.

Noteworthy additions are to be noted in the diagram for the determination of the efficiencies of longitudinal and diagonal ligaments between tube holes in cylindrical tube sheets which is inserted in the form of a folder (See Fig. 13 between pages 48 and 49) and the proposed Manufacturers' Data Report form which follows page 128 of the Appendix. Another change that will be readily noted results from the revision of the safety-valve rules embracing the transfer of the Tables of Discharge Capacities for direct spring-loaded pop safety valves to the Appendix. In addition, there are a number of other revisions which will prove of interest to those engaged in the boiler industry.

The edition of 1918 of the Boiler Code is slightly larger than the original edition, embracing 128 pages of text and the two inset folders (Fig. 13 and Figs. 34 and 35); with the Index, which in the new edition avoids the divisional arrangement, there is a total of 146 pages. It is issued in pamphlet form for general distribution, being obtainable in paper cover at 50 cents per copy to members and $1.00 to non-members. Arrangements are being made to issue the Code in the near future in cloth binding for the convenience of those who desire to use it for textbook or reference purposes; the price of the cloth-bound edition will be announced later.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of THE JOURNAL by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in THE JOURNAL, or brief articles of current interest to mechanical engineers.

The Sinking of the Steamship "Lucia"

TO THE EDITOR:

In response to your request, I am sending you particulars regarding the steamship *Lucia* upon which I presented a paper at the last meeting of the Society of Naval Architects and Marine Engineers.[1] The *Lucia* was an Austrian steamship with buoyancy boxes for which the design and calculations were made by the writer. The work was done at the instigation of the Ship Protection Committee created jointly by the Naval Advisory Board and the U. S. Shipping Board. This Committee consisted of Admiral H. H. Rousseau, A. M. Hunt and the writer.

The *Lucia* was torpedoed about 5 p. m., October 17, about 1250 miles off the Atlantic Coast on her way to the Mediterranean.

According to the evidence of the captain and other officers, the ship was struck in the engine-room compartment just forward of the after engine-room bulkhead on the port side, so low down that the double bottom was undoubtedly destroyed, as well as the drainage connections for the double bottom and other watertight compartments. The explosion was so low that no damage appeared to the plating on the outside of the hull, even when the ship rolled.

At the time of the attack the *Lucia* was drawing 27 ft. 6 in. forward and 28 ft. 6 in. aft, so it will be seen that the torpedo, instead of striking as is usual not more than 10 ft. below the water line, actually struck more than 20 ft. below. The engine room and hold No. 5, the next compartment aft, flooded immediately, and soundings showed water entering holds Nos. 5 and 6.

The ship floated with a slight list to port during the night of the 17th and the next day until 3.20 in the afternoon, or for something more than 22 hours.

The captain and gun crew stood aboard until shortly before the sinking, and stated that they were ready to fight the gun and resist submarine attack on the surface until that time. Nothing, however, was seen of the submarine before or after firing the torpedo.

About noon on the 18th the sea commenced to rise and the wash

[1] An abstract of this paper appears on page 56 of this issue.

of the sea dislodged and loosened the deck cargo of motor trucks. The drive of these trucks finally struck the hatch aft hold No. 6, which finally filled from the deck. The ship then settled aft, standing almost vertical before she finally went down.

It will be understood, as set forth in the paper, that the displacement of the double bottom had been depended upon for reserve buoyancy. This was partially eliminated by the unusual amount of fresh water carried, and the remainder by the destruction of the pump connections to the double bottom. The destruction of these connections also admitted water to all other compartments aft through the drainage connections, thus eliminating any buoyancy ordinarily maintained by watertight compartments.

Altogether it is to be noted that the torpedo in this instance made a perfect hit. It is hardly conceivable that it could be so precisely located by the hand of chance or coincidence.

At the time of the fitting out of the *Lucia* ships were being torpedoed at only a moderate distance from the coast, and mainly in the English Channel and approaches thereto. Had the *Lucia* been torpedoed anywhere within 100 miles of the coast she would in all probability have been safe. Attention should also be called to the fact that other vessels torpedoed in the engine room—destroying their bulkheads—have gone down in from eight to ten minutes.

While the result of this practical test of the *Lucia* is not all that was hoped for, the writer believes that when carefully considered in all its bearings, it is a very considerable contribution to the possibility of rendering ships, with the lives of their crews and their cargoes, more safe at sea.

William T. Donnelly.

New York, N. Y.

Working-Force Report—Stability Chart

To the Editor:

We have in use, in the employment department at the works of the Chester Shipbuilding Company, Chester, Pa., what we term a stability chart which may be of interest to readers of The Journal. The stability chart is another form of the turnover report and is based on the daily labor reports which are made out on blanks. The stability chart gives, by comparative colored lines, the details with regard to the working-force reports for each month.

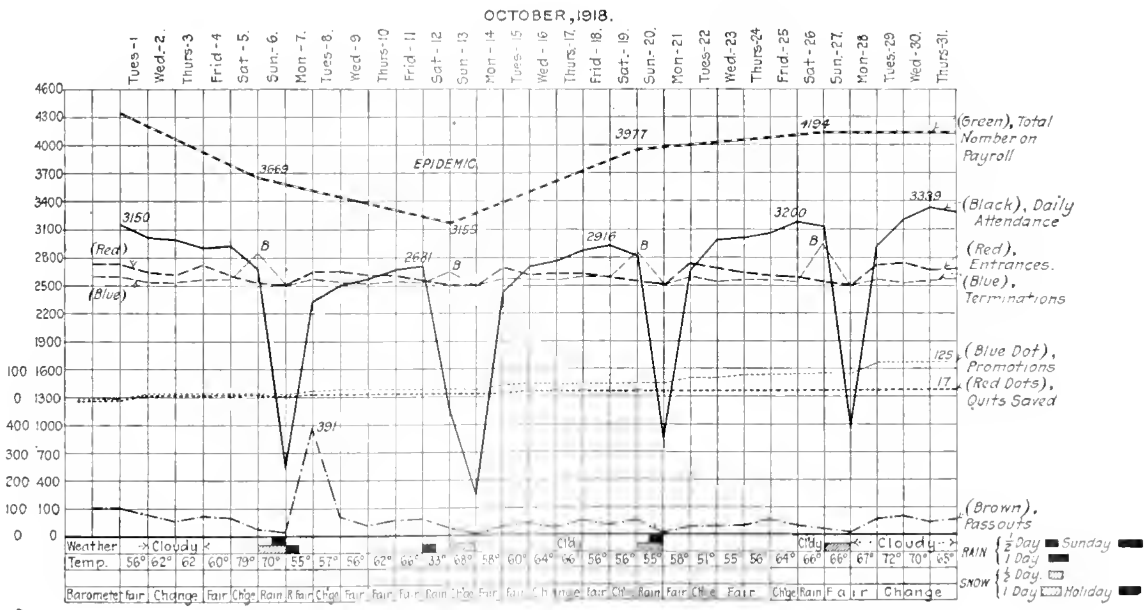
The chart uses two scales—300 men to the block for the daily attendance and payroll; 100 men to the block for all other reports.

The payroll is indicated by a green line near the top of the chart; the figures used in plotting this line are secured from the paymaster and indicate the number of pay envelopes given to the yardmen each Saturday. For that reason there is a regular gradation of line from one Saturday to the next. This line begins with the figures of the last payroll of the preceding month, and ends with the last payroll of the current month. Scale, 300 men to a block.

The figures from the black daily attendance line are secured from the daily labor reports and include both the day and night forces. As its name implies, it fluctuates from day to day, taking a decided drop on Sundays. A comparison of this line with the payroll shows the approximate number of daily absentees. This comparison of a daily with a weekly record will not be exact.

The terminations are shown in blue, the entrances in red. These two lines begin with the record of the last day of the preceding month, and are changed daily according to the number of men entered and terminated each day by the employment department. These lines usually follow each other quite closely, the terminations being greater at the end of the week, the entrances at the beginning.

The promotions in blue dot and the "quits saved" in red dot are cumulative. The lines begin at zero, and the positions of the



Stability Chart in Use at the Works of the Chester Shipbuilding Co.

lines on the last day of the month indicate the total number of promotions and quits saved during the month.

Brown ink is used for the "pass outs," a list of which is secured from the time department daily. The line begins where the line of the preceding month ended, and varies daily. The pass outs include all men who leave the yard during the day, and the number is affected by the weather to a large extent.

Sundays and holidays are indicated at the bottom of the chart, in purple and red, respectively. Columbus Day was not a holiday, yet its influence on the working force is made evident on the chart. The epidemic made its influence felt, likewise. The weather conditions and temperature are also indicated, as rain, excessive heat or extreme cold affect the working force, and likewise the stability chart.

The date and days of the week are placed at the top of the chart, making a concise report of the working force in such form that reasons and results are shown at a glance.

M. E. Hood.

EXECUTIVE COMMITTEE OF THE COUNCIL

Mortimer E. Cooley, *Chairman* .... Ann Arbor, Mich.

The Secretary's Letter

The Annual Meeting which has just closed developed a fine spirit and sounded a high note in respect to the ideals which the Society and its members are striving to attain. From the time of the conference of the Committee on Aims and Organization held just previous to the meeting and continuing, through the addresses and even in the papers, notably in the one by Mr. R. B. Wolf on the Non-Financial Incentives in Industry, this spirit was everywhere manifest.

The Society is in tune with the high purpose of the Nation, or to state the matter in another way, of which I have for a long time thought the engineering profession deserving, the engineer is as responsible as any other citizen for the high ideals of this Nation which President Wilson has been able to so forcefully state. It is highly creditable and encouraging to us either helping to form the Nation's ideals or being abreast of the times.

In keeping with our professions we have sent President Main to France in response to the invitation from the French engineers who are working under government auspices on reconstruction problems.

With the many tasks at home the Society needs also the constructive genius of the entire membership—first, in assisting all returning officers and men to positions. Please promptly write the Secretary of any opportunities under your observation. Second, in securing business for industries so they may be quickly adjusted to a peace basis. In either case, if you do not write the Secretary, at least notify the local committee of your city, which is one of the committees of "readjustment" for the Society. Third, in supplementing the work which our President will do abroad, and which, as we understand it is only preliminary. If you are available for foreign service, please advise the Secretary in what capacity you could best serve and the conditions under which you could go abroad.

Members will recognize that the emphasis in the above is on the things that we can do, rather than on the benefits to be derived by the individual members. While the Society is alive at all times to the necessity of improving its service to the membership, and suggestions are urgently requested in that regard, the Secretary believes that its resources should be devoted to the profession in so far as possible and that this should be the first consideration of a member, rather than what he may personally get out of the Society.

In this connection we take special pride in the purchase by the Society of *The Engineering Index,* elsewhere announced. This service we shall give regularly to the membership. We propose to make The Journal the most indispensable paper you receive.

Calvin W. Rice,
Secretary.

"Mechanical Engineering"

The first monthly publication of the Society was known as the "Proceedings," a title which correctly interpreted its contents, comprising the reports of the Annual and Spring Meetings, the New York meetings and the chronicle of its committee activities.

With the growth of the Sections, however, the material which came to the publication was considerably broader in its scope and the name was changed to "The Journal." The Sections now number 26, representative of nearly every part of the country, and other Sections are forming. Each Sections Committee is virtually an editorial committee which solicits contributions for its meetings and for later publication in THE JOURNAL—contributions which are representative of the engineering progress in the particular vicinity where the Section is located.

Added to these is the review of American and foreign periodicals which appears in THE JOURNAL, and now, beginning with this number, is the incorporation of The Engineering Index. The field of THE JOURNAL has become so broad, therefore, that the Publication Committee has decided to adopt the name "Mechanical Engineering" as correctly descriptive of its contents.

The Engineering Index

When THE JOURNAL was started in 1906, a committee, of which the late Professor Hutton was a member, was appointed by the Council to outline a plan for its development. An important feature which has since been worked out step by step by the Publication Committee was to be the reviewing and indexing of the large group of periodicals in the Library, comprising substantially the current engineering publications of the world.

The first step was taken in 1912 by the establishment of the Foreign Review, which later was extended to include English and American periodicals and a selected list of titles of articles in the technical press. During the past few months these selected titles have been greatly extended, and have covered the leading articles in mechanical engineering and related fields.

Beginning with this number of THE JOURNAL, another important step has been taken of great significance, in the purchase by this Society of the Engineering Index, published for many years by the Engineering Magazine Company and widely known among engineers and in libraries throughout the world as the leading index of current periodical literature.

The Engineering Index had its inception in the personal need felt by Prof. J. B. Johnson of Washington University, St. Louis, and who began in 1883 to index periodicals on his own account in order to keep more closely in touch with engineering progress. At that time he was a member of the Board of Managers of the Association of Engineering Societies which until within a few years has published a journal containing the papers presented before the several societies comprising the association.

At Professor Johnson's suggestion, the Index was incorporated in that journal and published by it until 1895, when its Board of Managers turned over the Index to the *Engineering Magazine*, with its greater facilities for the production of the Index.

The Index has since appeared regularly in the *Engineering Magazine,* and in *Industrial Management*, the title which the magazine now bears. It has also been issued as a separate publication for those who desire it in this form, and the items have been collated and published in yearly volumes.

It was felt by Mr. John R. Dunlap, publisher of *Engineering Magazine,* that its field had now become so specialized that the services which the Engineering Index could give would be greatly enhanced if the Index were to be conducted by an institution like this Society, with the facilities of the Engineering Societies Library at its disposal and with the possibility of coöperation with other similar organizations for its extensive development.

It requires but little imagination to picture the possibilities and the utility of such a descriptive index when brought to the point where it covers with thoroughness the whole field of engineering.

To show the spirit in which the transfer of the Index was made, two letters follow, one from the Secretary of this Society to Mr. Dunlap, and the reply from Mr. Dunlap.

DEAR MR. DUNLAP:

You have built up a distinctive service known as "The Engineering Index." You can be proud of the achievement. The Society in acquiring it, pledges to carry it on in the same spirit.

We will bring to the "Index" the facilities of the extensive Engineering Societies Library, the combined library of five great Societies, embracing over eleven hundred leading current engineering publications of all countries, and a reviewing staff of engineers specializing in bringing together the world's technical literature for a single subscription.

We propose to furnish this as an added service to all the members of The Society of Mechanical Engineers.

We accept your offer to assist us by your advice and counsel in taking over the "Index," extending it, and making it the most complete in the world.

Yours truly,

CALVIN W. RICE,
Secretary.

DEAR MR. RICE:

Thank you for your kind favor of the 29th instant, in relation to taking over THE ENGINEERING INDEX.

After having devoted more than 25 years to developing and maintaining that indispensable and priceless publication, I can promise you that engineers and specialists in every state in our Union and indeed in every quarter of the civilized world—will welcome the glad news that your Society has taken over this great work, and you are now definitely pledged to maintain and extend its invaluable service.

I have always found such ready and widespread appreciation of the INDEX, and especially its Clipping Bureau service, that I have never had any difficulty in making it pay its way—directly for the annual volumes, and indirectly for the monthly issues. Now that the publication will carry the official endorsement of your great Society, and now that you can enlist the active interest of all your members and in addition make an effective appeal for support to members of all the other great engineering societies, I confidently predict that ere long you will find it advisable to issue the INDEX as a separate monthly publication, precisely as we long ago found it necessary to publish it as an Annual.

Wishing you every success in the future development of the work, and assuring you of the cordial and continuous coöperation of myself and every member of our staff, I am,

Sincerely yours,

JOHN R. DUNLAP.

Employment Bureau of the Four Societies

The Society has the pleasure of announcing the establishment of an Employment Bureau under the auspices of the Secretaries of the four National Engineering Societies. This Bureau will have the same personal attention of the Secretary that he has always given to the employment service; and the Bureau will have the advantages which will accrue from the bringing together of the opportunities known to the four Societies.

Particular attention is being given to assisting men just about to leave the Government service or who have already left. The societies feel a special obligation to assist as a patriotic work in this reconstruction service. There will be no charge at the present time, and it is further hoped that in addition to helping members of the Society we may list all engineers who are seeking employment, and give proper references. These references will invariably be investigated, as the Bureau will be conducted solely for the benefit of well-known and reliable firms and thoroughly responsible engineers.

Department of Commerce to Manufacturers

The Department of Commerce is coöperating with American manufacturers in their efforts to study export trade problems. In this connection it has undertaken to investigate the markets for industrial machinery in Asia.

A circular letter has been sent by the Bureau to a number of prominent manufacturers offering them the opportunity to avail themselves of the facilities provided by the Bureau in supplying any desired information. It is stated that the Bureau is prepared to secure information involving any technical or commercial matters even of an intricate nature.

An appeal for donations of tools, machinery and equipment has been issued by the Tuskegee Normal and Industrial Institute for the training of colored young men and women. The Institute suffered a serious loss in the destruction by fire of its Trades Building.

Eightieth Birthday Anniversary of Captain Robert W. Hunt

THE eightieth birthday anniversary of Captain Robert W. Hunt, Past-President Am.Soc.M.E., was celebrated on December 9. Seventeen hundred invitations had been issued to a reception held in his honor at the Mid-Day Club in Chicago, and a large number of his friends availed themselves of the privilege of extending their felicitations to him at that time.

In the evening, the partners and associates in the firm of Robert W. Hunt & Co., with their wives, tendered a dinner to Captain and Mrs. Hunt, and a few of their intimate friends, at the Blackstone Hotel. There were about forty-five in attendance, and each guest received an autographed photograph of Captain Hunt, taken just a few days prior to his eightieth anniversary.

Two important announcements signalized the dinner, the first being a presentation to Captain Hunt by Mr. Samuel T. Wellman of an elaborately prepared testimonial of congratulation and affection, which had been adopted in resolution form by the officers and directors of the American Institute of Mining Engineers. The other event consisted of the announcement of the establishment of a fund guaranteed to be at least $5000, the income of which is to be offered as a prize each year to the author of the best paper on iron or steel subjects presented to the Institute. While the details of the plan have not been fully decided, still it is probable that the prize will be known as the Robert W. Hunt Prize, and the fund and its distribution will of course be managed by the Institute.

Robert Woolston Hunt was born on December 9, 1838, in Fallsington, Bucks County, Pa. His father, Dr. Robert W. Hunt, of Trenton, N. J., was graduated from Princeton College, Class of 1824, and from the University of Pennsylvania. His mother was Martha Lancaster Woolston. He spent several years learning the practical side of iron making in the rolling mills of John Burnish & Co., Pottsville, Pa., and later took a course in analytical chemistry in the laboratory of Booth, Garrett & Blair, upon the completion of which he entered the employ of the Cambria Iron Co., Johnstown, Pa., and for them on August 1, 1860, established the first laboratory in America as a direct part of an iron or steel organization.

In the fall of 1861 Mr. Hunt entered the U. S. Military Service, was in command of Camp Curtin, Harrisburg, Pa., served as mustering officer for the state of Pennsylvania, with the rank of captain, and in 1864 assisted in recruiting Lambert's Independent Mounted Company P. V., and was mustered into the United States service as a sergeant, having tossed up with a friend who had also participated in recruiting the company, as to which one should receive a lieutenant's commission. Upon being mustered out of service he returned to the employ of the Cambria Iron Co., and was sent by them to the experimental Bessemer works at Wyandotte, Mich., of which they were part owners. He was placed in charge of those works in July 1865, and so continued until May 1866, when the Cambria Company called him back to Johnstown to take charge of their steel business, they intending to at once begin the erection of a Bessemer-steel plant. This, however, was not done for several years, and in the meantime, the Cambria Company undertook the rolling of steel rails for the Pennsylvania R.R. Co. from ingots produced by the Pennsylvania Steel Co.'s works at Steelton, Pa., that company's rail mill not being completed. He had charge of the steel for this operation, and these were the first steel rails made in America on a commercial order.

Later Mr. Hunt assisted John Fritz, Cambria's chief engineer, in designing and building their Bessemer works, and assumed charge of it on its completion July 10, 1871, so continuing until August 1873, when he resigned his position. On September 1, 1873, he entered upon the duties of superintendent of the Bessemer works of John A. Griswold & Co., Troy, N. Y. In March 1875 he became general superintendent of the Albany & Rensselaer Iron & Steel Co., which had acquired the works of John A. Griswold & Co. and Erastus Corning & Co. This organization became later the Troy Steel & Iron Co., he remaining in charge until April 1888. During those years he almost completely rebuilt the various works of the company, and also erected a large blast-furnace plant of the most complete character.

Mr. Hunt has taken out several letters patent on steel and iron metallurgical processes and machinery, both individually and in conjunction with John E. Fry, Wm. R. Jones, Dr. August Wendel, and Max M. Suppes. He put in the first automatic rail-mill tables, and later the Hunt-Jones-Suppes rail-mill feed tables were used under licenses by the majority of the rail mills in the United States.

On December 5, 1866, he was married to Miss Eleanor Clark of Ecourse, Mich. In April 1888 he established the Bureau of Inspection, Tests and Consultation of Robert W. Hunt & Co., with principal offices in Chicago, Ill., to which city he removed in the spring of 1888. He served three terms as commander of the John A. Griswold Post No. 338, G. A. R., of Troy, from which office he resigned on removing from that city.

Mr. Hunt is a member of the American Institute of Mining Engineers, and was president of the Institute in 1883, and again in 1906. He was president of The American Society of Mechanical Engineers, in 1890. He is a member of the Western Society of Engineers and was its president in 1893. He is also a member of the American Society of Civil Engineers, Canadian Society of Civil Engineers, the Institute of Civil Engineers, the Institution of Mechanical Engineers, and the Iron and Steel Institute of England. He is a member of the American Society for Testing Materials, and served as its president in 1912. He is the American member of the council of the International Association for Testing Materials.

In 1912 Mr. Hunt was awarded by the John Fritz Medal Committee, representing the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers, the John Fritz Medal, "for his contributions to the early development of the Bessemer process."

Mr. Hunt has contributed many papers to the proceedings of the several societies of which he is a member, and frequently lectures before scientific bodies. He is and has been for many years a trustee of the Rensselaer Polytechnic Institute, Troy, N. Y. In 1916 he received from that institution the honorary degree of Doctor of Engineering.

Mr. Hunt is a member of the Chicago, Chicago Engineers', Mid-Day, Saddle and Cycle, South Shore Country, Illinois Athletic, Glen View, Chicago Golf, Winnetka Country, Montreal Engineers', Engineers' of New York and Mexico City Country Clubs. He has always been interested in outdoor sports and was in his earlier life a cricket and baseball player and is now an enthusiastic golfer. M. E. C.

A Word from Capt. Hunt

In response to the Society's birthday greetings to Mr. Robert W. Hunt, Past President, Am.Soc.M.E., upon the occasion of his eightieth birthday, the Secretary has received the following note of appreciation:

DEAR SIR:

Permit me, through you, to thank the Council for their highly appreciated birthday expressions, and I beg to assure them that their action did much to add to my happiness on "the day."

With my best assurance of my personal regards to yourself, I remain,

Yours truly,
(Signed) ROBERT W. HUNT.

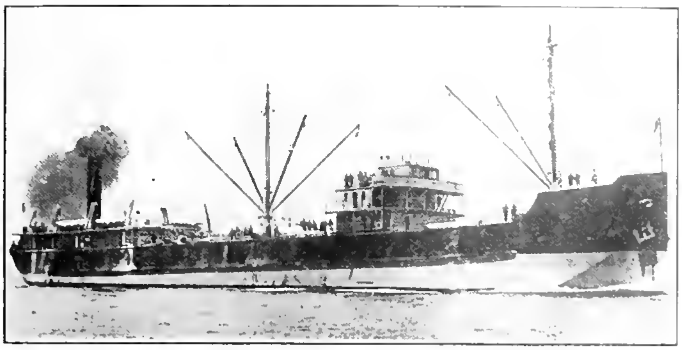
Annual Meeting Excursions

IN arranging for excursions for the Annual Meeting, it was planned to have them occur on two days, Wednesday, December 4 and Friday, December 6. On Wednesday, there were two excursions—a visit to the Hispanic Society at Broadway and 156th Street, in the morning, and in the afternoon a visit to the Brooklyn Navy Yard. A party of about 75 participated in the afternoon excursion, and arrangements were made with the Fifth Avenue Coach Company to furnish two busses, each accommodating 45 persons.

The party was received at the Navy Yard by Rear-Admiral John D. McDonald, U.S.N., and his staff, who accompanied it on the tour of inspection from start to finish. One of the most interesting features of this trip was the inspection of the electric-motor-driven, oil-burning superdreadnought *New Mexico*. Every facility for viewing the features of the work at the Navy Yard was afforded the visitors, who were very appreciative of the courtesies extended.

On Friday morning, about 50 members visited the plant of the Seaboard By-Products Coke Company, Kearny, N. J. The party was met at Summit Avenue by automobiles furnished by the Seaboard Company. This was also an interesting trip.

Over 100 members participated in the inspection of the Concrete steamship *Faith* on Friday afternoon. All the members of the party were permitted to go aboard the steamer which was at the Christopher Street dock.



Concrete Steamship "Faith"

Upon invitation of Walter S. Finlay, Jr., Mem.Am.Soc.M.E., superintendent of motive power of the Interborough Rapid Transit Company, a number of members visited the 74th Street plant and inspected the new 60,000-kw. turbine.

An invitation was extended to the members to visit the Steel Utilities, Inc., Newark, N. J., at any time during the meeting, for the purpose of inspecting their automatic spacing machine used in fabricating iron and steel.

It was requested that an excursion be arranged to the plants of the Wright-Martin Air Craft Corporation and the Eastern Asiatic Company, but owing to war conditions and other reasons, these plants were not available for inspection.

Harry J. Marks, *Chairman*,
Excursions Committee.

Excursion to Aberdeen Proving Ground

Members of the Society were the guests of the War Department, Engineering Division of the Ordnance Department, Colonel James B. Dillard, Chief, at the Aberdeen Proving Ground, December 13, at probably one of the most complete demonstrations ever given.

At the Annual Meeting, December 5, Colonel Dillard gave an illustrated address of the notable achievements of the Ordnance Department of the United States Army in the production of railway artillery, an account of which is given elsewhere in this number. Many of the guns and rifles of the largest caliber have been completely developed within the period of the war. Following the address, Colonel Dillard invited the members of the Society to the Proving Ground at Aberdeen, midway between Wilmington and Baltimore, where tests were made of guns of all kinds, caterpillar tractors, etc.

The Proving Ground contains about 35,000 acres, is 14 miles long and 6 miles wide. Construction was started Nov. 1, 1917, by 20 officers and enlisted men. A year later there were 301 officers, 4846 enlisted men, 968 civilians and 2500 workmen. In the proof of guns, carriages and ammunition, 6000 to 8000 rounds are fired daily, and the maximum capacity is 12,000 rounds per day, and this would have soon been reached if the war had continued.

Upon arriving at the Proving Ground at 10 a. m., the visitors were first taken to the Trench Warfare Range. The 3-in. and 6-in. Stokes trench mortar was first demonstrated, a total of 240 rounds being fired with 10 mortars, some with an elevation of 75 deg. With the 240-mm. French type of trench mortar 4 rounds of high-explosive shells were fired at 75 deg. elevation, and 4 rounds with the 11-in. Sutton-Armstrong trench mortor; elevation 45 deg., range 2100 yd. Then followed a salvo of 13 rounds with the 8-in. Livens gas projector, at a range of 1850 yd. Finally, 40 shots were fired with some 4-in. Stokes trench mortars, using incendiary shells, American smoke shells, and British heavy smoke shells. The entire demonstration with the roaring guns and smoke barrage was a good imitation of modern warfare.

The party then proceeded to the Main Proof Battery and observed the following guns in action:

37-mm. gun, model 1916; weight 463 lb.; range 2625 yd.; spring and oil recoil system.

75-mm. field gun, model 1897, French, on 1918 carriage; hydro-pneumatic recoil, 47 in. long; weight complete, 2850 lb.; shell 12 lb.; range, 6900 yd. A 1916 model American gun and a 1917 model British gun of the 75-mm. size were also tested.

155-mm. howitzer, model 1918, of Schneider design, and another of Filloux design, were demonstrated, firing a 95-lb. projectile a distance of 10,300 yd. and 19,000 yd. respectively. Total weight, 8200 lb.; hydro-pneumatic recoil; maximum elevation, 42 degrees.

American 4.7-in. field gun, 1906, with oil and spring recoil; shell 45 lb.; maximum elevation, 15 deg. Total weight, 8000 lb.

Bethlehem 6-in. howitzer; hydro-pneumatic recoil; projectile 90 lb.; 13,500 yd.

Vickers, Mark VI, 8-in. howitzer, hydro-pneumatic recoil system; air pressure in recuperator being 700 lb. per sq. in.; recoil 24 to 56 in. long; projectile, 200 lb.; 10,500 yd. Total weight, 10 tons.

Vickers, Mark I and II, 9.2-in. howitzer. Projectile, 290 lb. At 45 deg. elevation, range of Mark II, 12,700 yd.

At this Range are located several constant temperature magazines for the storage of powder, also other buildings in which powder charges for the various guns are made up into their proper weights.

After luncheon an inspection was made of the following artillery tractors of the caterpillar type, designed and built by the Ordnance Department:

75-mm. field gun, 1916, mounted on a standard 2½-ton Ordnance tractor; maximum speed 16.25 miles per hour.

2½-ton special tractor for 3-in. field gun.

5, 10 and 20-ton artillery tractors.

45, 75 and 120-hp. standard Holt artillery tractors.

Mark I special tractor for 8-in. howitzer.

One of the great achievements is the self-propelled howitzer, which went down a ravine at least 10 ft. below the level of the surrounding ground, went up the other embankment and felled a tree 17 in. at the butt, and within a few seconds took position and fired a round of shells.

A Ford armored tank was exhibited, driven by two standard Ford engines. One man maneuvered the tank, the other operated its Marlin anti-aircraft machine gun.

Aeroplanes and hangars attached to the Proving Ground for work in bomb dropping, experimental and proof tests were next inspected. Then the visitors were taken to the Railway Artillery Range, where the following types of railway artillery were inspected and seen in action:

5-in. and 6-in. gun carriages, models 1917 wheel mounts.

7-in. navy gun on model 1918 railway mount; glycerine and spring recoil, 19-in. long; projectile 165 lb.; charge of powder, 57.7 lb.; elevation, 15 deg.; traverse, 360 deg.; range, 17,000 yd.

8-in. Barbette carriage, 1918, for 8-in. seacoast gun, 1888; oil and spring recoil, 48 in. Fires from fixed underframe, laid on road-bed ties, car braced by outriggers; projectile, 200 lb., powder 68 lb.; 20,000 yd.; elevation 42 deg.; traverse 360 deg. Total weight of unit, 173,000 lb.

12-in. seacoast mortar, model 1890 M1, on 1918 carriage and R. R. car. Projectile, 700 lb.; powder 65 lb.; elevation, 65 deg.; traverse, 360 deg. Total weight of unit 174,000 lb.

12-in. gun on sliding mount carriage. Recoil absorbed by whole carriage sliding back 48 in. upon the I-beam under-frame. Total weight of mount, 600,000 lb.

14-in. army gun, model E, on R. R. mount. Recoil, 60 in. long. Fired either from fixed emplacement consisting of special base ring laid in roadbed which allows elevation to 30 deg., or fired directly from track by laying special tracking, which allows 22-deg. elevation. Pro-

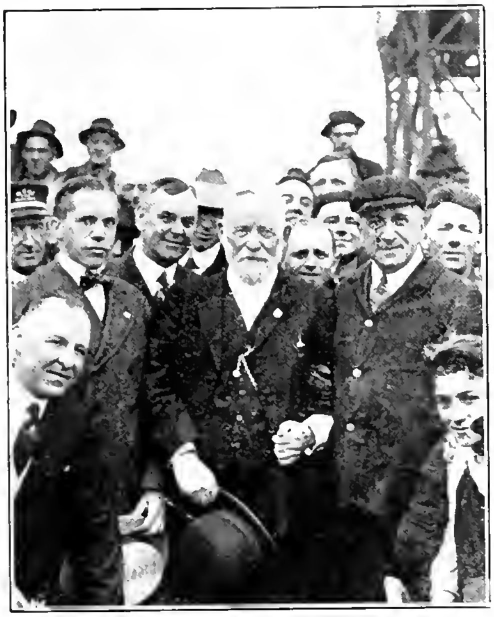
jectile, 1200 lb., powder, 450 lb.; muzzle velocity, 2900 ft. per sec.; maximum range, probably 40,000 yd. Total weight of unit, 400,000 lb.

16-in. howitzer, model E, mounted on 1918 car. Oil and spring recoil, 48 in. long. Fired either from a specially-laid emplacement in the road bed, allowing 65-deg. elevation, or fired direct from track, brakes tightened, car recoiling 25 ft. Engine-driven winch to return car after each shot. Projectile, 1660 lb. Maximum muzzle velocity, 1900 ft.-sec. Maximum range obtained at 45-deg. elevation, 24,000 yd. Total weight of unit, 300,000 lb.

The officers in charge at the Proving Ground were specially thoughtful, explaining every test before it was made. They had a special train for the party, which numbered over 300, and escorted the party back to the railway station for transfer to the main line over the Pennsylvania Railroad. This excursion will long be remembered, not only for the great interest, but also as promoting the pride of every one in the country's achievements.

Valued Portraits

The accompanying snap shot, first published in *The San Franciscan*, was recently sent us by E. C. Jones, Secretary of the San Francisco Section. It gives excellent likenesses of three of the Society's distinguished members, Charles Piez, then Vice-President of the U. S. Shipping Board (at the left); the late



Messrs. Piez, Dickie and Schwab at Morse Shipbuilding Co.'s Yards, Oakland, Cal.

George W. Dickie, whose memory will long be cherished by his hosts of friends; and our new Honorary Member, Charles M. Schwab. The photograph was taken several months ago, just after Mr. Schwab had driven the first rivet in a 10,000-ton tanker at the Morse Shipbuilding Company's yards, Oakland, Cal.

American Engineering Standards Committee

At the present time many bodies are engaged in the formulation of standards. To secure (a) greater uniformity in the rules for procedure in the different organizations, (b) more representative committees engaged in the work, (c) more consideration of all the allied interests, (d) to avoid duplication of work, (e) "standards" proposed for the same thing that differ only slightly from each other often on unimportant details, (f) to anticipate the difficulty of obtaining agreement between the proposers of overlapping standards, the American Society of Civil Engineers, The American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and the American Society for Testing Materials, appointed a committee to consider the advisability of coöperating in Engineering Standardization. As a result of its deliberations this committee recommended that these societies form a permanent organization by appointing a standing committee to carry on this important work, throughout the entire field of engineering standardization.

This recommendation was approved by the five societies and their representatives on the proposed committee appointed. On October 19, 1918 these representatives met and organized as the American Engineering Standards Committee.

The following is the organization of the Committee:

MEMBERS

American Society of Civil Engineers

John H. Gregory, Consulting Engineer, 170 Broadway, N. Y.

Martin Schreiber, Chief Engineer, Public Service Railway Co., 80 Park Place, Newark, N. J.

Harry N. Latey, Railway Dept., General Electric Co., 30 Church St., New York City.

American Institute of Mining Engineers

George C. Stone, Chief Engineer, New Jersey Zinc Co., 55 Wall Street, New York City.

Joseph W. Richards, Professor of Metallurgy, Lehigh University, South Bethlehem, Pa.

Arthur L. Walker, Professor of Metallurgy, School of Mines, Columbia University, New York City.

American Society of Mechanical Engineers

Henry Hess, 308 Bailey Building, Philadelphia, Pa.

Henry H. Vaughan, Vice-President, Dominion Bridge Co., Montreal, Quebec, Canada.

William F. Kiesel, Jr., Asst. Mechanical Engineer, Pennsylvania Railroad, 2320 Broad St., Altoona, Pa.

American Institute of Electrical Engineers

Comfort A. Adams, Lawrence Professor of Engineering, Harvard University. Pres. Am. Ins. El. Engrs.

Harry M. Hobart, Consulting Engineer, General Electric Co., 10 Morris Ave., Schenectady, N. Y.

Nathaniel A. Carle, Chief Engineer, Public Service Electric Company, Newark, N. J.

American Society for Testing Materials

John A. Capp, Chief of Testing Laboratory, General Electric Co., Schenectady, N. Y.

Alfred W. Gibbs, Chief Mechanical Engineer, Pennsylvania Railroad Co., Philadelphia, Pa.

A. A. Stevenson, Vice-President, Standard Steel Works Co., Philadelphia, Pa.

EXECUTIVE OFFICERS

Comfort A. Adams, Chairman, 29 West 39th Street, N. Y. City.

George C. Stone, Vice-Chairman, 55 Wall Street, New York City.

Clifford B. LePage, Acting Secretary, 29 West 39th St., N. Y. C.

EXECUTIVE COMMITTEE

Comfort A. Adams, George C. Stone,
Harry N. Latey, Henry Hess,
John A. Capp.

RESEARCH COMMITTEE

The following progress reports of the Sub-Committees on Fluid Meters and on Bearing Metals were presented at a meeting of the Research Committee held on December 5, 1918:

Report of the Sub-Committee on Fluid Meters

This sub-committee, formerly known as the Sub-Committee on Flow Meters, has been at work for two years. In 1917, for the winter session, a preliminary report in six sections was prepared for discussion by the members. Discussion and correction was carried on by correspondence, and the report as a whole was revised and the work redistributed at the June meeting at Worcester. The pressure of war work prevented very much active work being done except on Section II, which covers the develop-

ment of suitable formulæ for all of the many types of flow meters.

At the present time Section I, which is an analysis of the problem, has been completed and a classification of all types of flow meters has been made.

The second section, which involves the development of formulæ and suitable constants for the application of these formulae to all conditions for the Pitot Tube, Venturi Tube, the Thin-Disk Orifice, the Thick-Disk Orifice and other similar pressure-developing devices, has been practically completed and will shortly be submitted to the members for final revision.

The sections into which the original report was divided and on which the work is based, will be restated for convenience.

Section I. Analysis of the problem.
Section II. Formulae and constants for the various elementary devices.
Section III. Accuracy and characteristics of the indicating and recording devices as pressure gages.
Section IV. The influence of installation.
Section V. Operating characteristics, cost and desirability.
Section VI. Testing methods.

In view of the situation as developed by the classification of meters under Section I, it appears that the scope of the original Sub-Committee on Steam Flow Meters was undesirably limited. We find that in classifying and examining the features of steam-flow meters, we became necessarily involved in the study of fluid meters as a whole. Upon request to the Research Committee, therefore, the title of this sub-committee has been changed to the Sub-Committee on Fluid Meters.

The general work such as in Sections I, II and III will cover the whole field; but for the present Sections IV, V and VI will concentrate on that group of fluid meters known as flow meters.

The sub-committee has requested an appropriation of $1500. for research to be carried on at two of the college laboratories, in order to check the characteristics of the primary devices with each other and with the previous experimental data. The Research Committee has recommended this appropriation. The object of this sub-committee is to prepare a textbook on the theory and use of fluid meters sufficient for standard reference.

The sub-committee originally consisted only of five members, none of whom were manufacturers. However, about two years ago it became apparent that the best work would be done by inviting the manufacturers to coöperate. To this end representatives have been appointed from the staffs of most of the principal flow-meter manufacturers and they have cordially assisted the remainder of the committee by very effective work. It will probably prove necessary to invite more manufacturers to send representatives for the committee as the work proceeds.

In all probability, another year will see that division of the work applying to flow meters very nearly completed.

Sub-Committee on Fluid Meters,
R. J. S. Pigott, *Chairman.*

Report of Sub-Committee on Bearing Metals

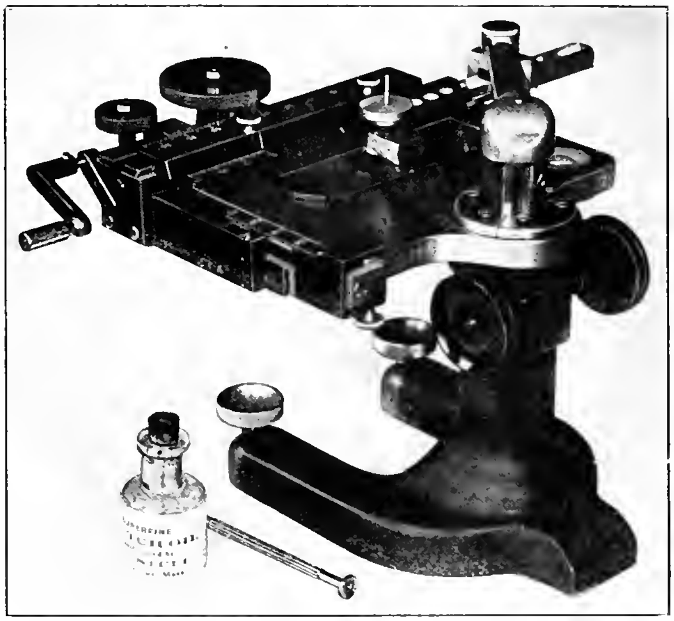
At the time our sub-committee was appointed it seemed wise to first make a complete survey of the existing literature on the subject of bearing metals. This was undertaken by instituting a search in the Engineering Societies Library under the direction of the librarian. A list of references was accordingly supplied to the members of our committee, whereupon independent work was begun with an effort to collate and harmonize the opinions and experiences as presented by the various writers.

Our efforts, however, proved unsuccessful owing to the incomplete, inaccurate and positively contradictory statements that were found upon this subject. We came to the unanimous conclusion that any further efforts in this direction would be hopeless and futile. We thereupon considered the subject of patents; we had a complete search made of the United States patents and made a complete digest of them, together with a search of the English and German patents. All this, however, was equally unsatisfactory owing to the extravagantly optimistic and misleading statements set forth in many of these documents.

For the foregoing reasons our efforts of compiling or collating data on bearing metals have been held in abeyance if not completely abandoned, and during the past year active research work has been done instead.

Microscopic and physical metallurgy has become an exceedingly interesting subject during recent years and this, perhaps, more than any other subject, has a most direct relation with bearing alloys. Recent writers on metallography have disclosed many facts directly bearing upon our subject. Microscopy, chemistry, and metallography give us the number of different crystals, their composition, size and orientation in the various alloys, but the physical property of the respective hardness of these different crystals has never been investigated.

The latter subject, therefore, seemed the most inviting problem and for that reason we have given this our undivided attention during the last year, as far as time permitted. We have now proven conclusively that it is both possible and practical to study



Instrument for Use in Studying Hardness of Individual Crystals

the individual crystals of the bearing alloys with respect to their hardness.

We have perfected an instrument by means of which we are able to pass a very sharp point over the crystals as they are presented on a highly polished surface of the alloy. The great difficulty we encountered was that of finding a suitable substance which could be ground with a sufficiently high degree of accuracy and which at the same time was able to withstand the abrasive action of the harder crystals. We experimented with various grades of steel, the metal tungsten, diamonds, sapphires and tourmaline. We believe we have found an entirely satisfactory material for all requirements in the leuco-sapphire. We have been able to grind this material to a point where we have apparent absolute sharpness with a magnification of 600 diameters.

The shape of point we have found to be most satisfactory is in the form of the corner of a cube mounted in such a manner that the diagonal of the cube is normal to the surface tested, and an edge of the cube directly in the line of motion.

We have been very fortunate in being able to secure from the experimental department of the Spencer Lens Company of this city the necessary highly skilled workmen to do this work. Results so far are very encouraging.

Sub-Committee on Bearing Metals,
C. H. Bierbaum, *Chairman*
J. A. Capp
H. Diederichs

THE NEW OFFICERS OF THE SOCIETY

President, 1918-1919

Mortimer E. Cooley

Mortimer Elwyn Cooley, Dean of the Colleges of Engineering and Architecture of the University of Michigan, and President of The American Society of Mechanical Engineers for 1918-19, was born at Canandaigua, N. Y., March 28, 1855.

He graduated from the United States Naval Academy in 1878 and soon after graduation was ordered, with his classmate, Ira N. Hollis, to the U. S. S. *Quinnebaug*, then fitting out at the Norfolk Navy Yard preparatory to a cruise in the Mediterranean. The ship sailed the following December and Cooley spent 15 months on the *Quinnebaug* and then returned to America on the U. S. S. *Alliance*.

During the winter of 1879-80 he had charge of repairs on the *Alliance* at the Norfolk Navy Yard and in the latter year went with the *Alliance* on a cruise to Newfoundland to survey the banks for sunken rocks that had been reported. On the return trip the ship touched at Boston and Norfolk and was headed for the West Indies. At Savannah the young officer was detached and ordered to the Bureau of Steam Engineering, where he remained six months, until July, 1881, in the drafting and design department.

He was then detailed to the University of Michigan for three years under a law which permitted the Secretary of the Navy to detail engineer officers as professors of "Steam Engineering and Iron Shipbuilding," and thus began his long connection with the University which has been his life work and has covered a period of nearly forty years.

It is interesting to note in this connection that mechanical engineering was taught at the University of Michigan as early as 1868, at which time Prof. DeVolson Wood, later of Stevens Institute of Technology, was professor of civil engineering. The prime mover in mechanical engineering was Prof. S. W. Robinson, afterwards at the University of Illinois and Ohio State University. While the curriculum of mechanical engineering has since remained, the degree was abolished in 1870 and not reëstablished until the time of Professor Cooley's administration 11 years later.

One of the first men with whom Mr. Cooley became acquainted in Michigan was Past-President Jesse M. Smith, who had a consulting engineer's office in Detroit. Mr. Smith and Mr. Cooley were the first two college-trained mechanical engineers in the State of Michigan. Mr. Cooley tells of the difficulties in the way of consulting practice in the early days, an instance being the protest of a large lumber company at a bill of 10 dollars a day for services in the direction of economy of fuel, on the ground that there was more fuel then could be burned, anyway, so that there was no need for economy.

After Professor Cooley's detail of three years was ended the regents of the university secured a year's extension of his time; but in 1885 he was ordered to the Pacific Station for duty, whereupon the regents asked him to resign from the Navy to accept the chair of mechanical engineering at the University. This he did and his resignation was accepted December 31, 1885. In the same year the University conferred upon him the honorary degree of M. E. He became Dean of the College of Engineering in February, 1904, and of the College of Architecture in 1913. He received the degree of LL.D. from the Michigan Agricultural College in 1907; and the degree of Eng.D. from the University of Nebraska in 1911.

When Admiral Sampson made his report on the destruction of the *Maine*, at the outbreak of the Spanish-American war, Professor Cooley wired the engineer-in-chief of the Navy, tendering his services. These were accepted and he served during the war as chief engineer of the *Yosemite*, a converted Morgan liner manned by Michigan State Naval Militia.

The *Yosemite* first convoyed a munition ship to Key West and then proceeded to the blockade off Havana. After a single night on this blockade she was ordered to convoy the *Panther* with marines from Havana to Guantanamo, where they were successfully landed, the first American troops to land on Cuban soil. The *Yosemite* was also on blockade duty off Santiago and off San Juan, and for a time off the Jamaica coast to intercept blockade runners. At San Juan she engaged in a five-hour battle with the Spanish forts, gunboats and torpedo boats, as a result of having intercepted a Spanish ship which was putting in with a cargo of munitions. The *Yosemite* fired from 250 to 300 shots and twice drove the gunboats and torpedo boats into the harbor.

During the blockade a serious fire broke out in the coal bunkers of the *Yosemite* which was so deep down in the pile of coal that the crew could not reach it with water from the pumps. Chief Engineer Cooley recalled a method of sinking piles by means of a water pipe attached to the pile, which was used on the Missouri River, and applied it successfully to quench the fire. He used a slice bar along which a hose was triced, with the nozzle near the point, and, with the water discharging through the hose, the bar and hose were easily forced into the coal and the fire extinguished.

Mr. Cooley was attached to the League Island Navy Yard for a time following the war, first as chief engineer in charge of the machinery of a number of ships and then as assistant chief engineer of the yard. After 10 months in the service his discharge was personally handed him by the commandant of the yard with the highest commendation for his efficient work.

Mr. Cooley returned to the University in 1899 and during the years following undertook a large amount of important appraisal work.

A citizens' committee, of which Governor Pingree of Detroit was chairman, appointed to appraise the Detroit street railways, asked Professor Cooley to evaluate the power plants, rolling stock, stores and supplies. This was an urgent piece of work that had to be done quickly. The appointment was made on a Friday, the staff was organized on Saturday and the report made the following Saturday. The value of the property was $2,000,000.

The state legislature of Michigan having ordered an investigation to determine whether an ad valorem basis should be substituted for the specific basis in taxing railroads, Mr. Cooley, in 1890, at the request of Governor Pingree and the State Tax Commissioner, undertook the valuation of the railways and with a force of 150 men completed the field work in 90 days.

This covered 10,000 miles of railway valued at $200,000,000, to which in the process were added the telegraph and telephone lines, plank roads and river improvements.

This investigation led the legislature to adopt the ad valorem basis of taxation which greatly increased the amount of the taxes. The railroads brought suit to enjoin collection and in 1903-4-5 the properties were reappraised under Mr. Cooley's direction at a value for the railways of $240,000,000, an increase of $40,000,000. The state finally won the suit in the U. S. Supreme Court.

In 1902 Mr. Cooley assisted in the appraisal of the mechanical equipment of Newfoundland railways and in 1903 acted as consulting engineer in the Wisconsin railroad appraisal. In 1906 he was a member of the Traction Valuation Committee, Chicago; in 1907 appraised Michigan telephone properties; in charge of appraisal of hydro- and steam-electric properties and railroads for the Michigan Railroad Commission since 1910. The total value of the property with which he has been concerned in appraising is 1¼ to 1½ billion dollars, of which 85 to 90 per cent has been for the public.

Since 1906 he has investigated public utilities in Minneapolis, Milwaukee, Cleveland, St. Louis, Boston, New York, and several other cities.

From 1907 to 1912 he acted as Chairman of the Block Signal and Train Control Board, Interstate Commerce Commission.

In 1893, at the time of the Chicago Exposition, Mr. Cooley was one of the members of the Engineering Committee; also at the time of the Pan American Exposition he was on the Committee of Awards.

For 16 years, 1895-1911, he was senior engineer officer of the Michigan State Naval Militia. Since July last he has been District Educational Director of the 7th District (Illinois, Wisconsin and Michigan) in charge of collegiate training in the Students'

Army Training Corps, organized under the General Staff, U. S. Army.

Mr. Cooley was vice-president of the American Association for the Advancement of Science (1898); director of the American Society of Civil Engineers (1913-1916); vice-president of the Society for the Promotion of Engineering Education (1908-09); president of the Michigan Engineering Society (1903). Also he is a member of various other Societies and Clubs.

He became a member of The American Society of Mechanical Engineers in 1884 and served as Vice-President during the year 1902-03, and in 1916-17 as chairman of the executive committee, Detroit Section.

Vice-Presidents, 1918-1920

Fred R. Low

Fred R. Low, a Vice-President of the Society for two years, was born at Chelsea, Mass., April 3, 1860, and received his education in the public schools of that city.

He worked as a clerk in the Boston office of the Western Union Telegraph Company, where he learned telegraphing and stenography. He then became stenographer for Thomas Pray, Jr., editor of the *Boston Journal of Commerce*, leaving this position to take charge of the steam engineering section of the paper. He did some indicator work, testing, etc., among the New England mills.

In 1888 Mr. Low became Editor of *Power*, the position which he still holds. In this position he has won distinction not only for the publication itself but as an authority on power-plant subjects and one whose advice is often sought in relation to engineering matters. Last September, the thirtieth anniversary of his editorship was celebrated and Mr. James H. McGraw, the head of the McGraw-Hill organization, publishers of *Power*, said: "*Power* was founded on a great idea; the idea offered a great opportunity for a man to develop it; Fred Low proved to be the happy man and developed the idea into a great publication and at the same time developed himself into a great editor."

In the early days of *Power*, Mr. Low filled a most useful service by lecturing to stationary engineers' organizations throughout the country upon elementary power-plant topics and publishing one of these lectures each month. There can be no doubt but that this work helped greatly to elevate the engineers of many plants in an educational way.

Mr. Low was elected to membership in the Society in 1886 and has served on the following committees of the Society: Publication, Public Relations, Boiler Code, Power Test, Aims and Organization, and is the representative of the Society on the Joint Committee for the Classification of Technical Literature. Mr. Low is the author of books on The Compound Engine, Condensers, The Steam Engine Indicator and also of The Power Catechism.

Henry B. Sargent

Henry Bradford Sargent, a manufacturer of New Haven, Conn., was born in New York City, March 4, 1851. His ancestors emigrated from England before 1670, and his family began manufacturing in 1814 at Leicester, Mass.

He graduated in 1871 from Sheffield Scientific School, Yale University and entered the service of Sargent & Company, manufacturers of small hardware and tools, New Haven. He worked his way up in this organization and became assistant superintendent; was elected vice-president of the company in 1887, and soon after became general manager of the extensive works. For many years he was the acting chief executive of the company, and in 1917 he was made president.

For many years Mr. Sargent has been a trustee of Yale University, he is a member of the Yale Engineering Society, the Connecticut Academy of Arts and Sciences, and The Franklin Institute, Philadelphia. He has been a member of this Society since 1898, and was made a member of the Local Sections Committee during the administration of President Hollis. He served for several years on the Committee of the New Haven Section, and as Chairman was active in the organization of the Connecticut Section.

For three years he was a member of the New Haven City Government, and has been director of the Connecticut Manufacturers' Association, director of the largest local bank and a member of various other national and local associations.

John A. Stevens

John A. Stevens, consulting mechanical engineer of Lowell, Mass., was born at Galva, Ill., in 1868. He was graduated from the East Saginaw High School and studied one year at the University of Michigan. He served a three years' apprenticeship in the machinists' trade with Mitts and Merrill, Saginaw, Mich., after which he was engineer on several of the lake steamers. At the age of 27 he was granted an unlimited engineer's license for ocean steamships.

In 1893 he came East to enter the employ of the International Navigation Company of New York and he served as engineer on board some of their largest ships. On the *St. Paul* of this line, he was first assistant engineer. In 1896 he accepted the position of chief engineer with the Merrimack Mfg. Co., Lowell, Mass., and was very successful in improving the various steam-power installations of this company, making boiler trials, economy tests, etc.

In 1909 he continued this work for the company, but left its employ to go into private consulting engineering practice. He has been granted a number of patents for water-tube steam boilers and superheaters.

He was appointed by Governor Guild in 1907 on the Massachusetts Board of Boiler Rules and after serving three years he was appointed by Governor Draper to serve a similar term. Mr. Stevens became a member of this Society in 1902 and was one of the seven members originally selected to serve on the Society's Committee "to formulate standard specifications for the construction of steam boilers and other pressure vessels and for the care of the same in service," now known as the Boiler Code Committee, and he has served actively on this committee as chairman, continuously since its organization in 1911. He served as one of the Managers of the Society from 1915 to 1918.

Besides membership in this Society, Mr. Stevens is a member of the Society of Naval Architects and Marine Engineers and of the National Association of Cotton Manufacturers. In May 1918 he was presented a medal by the latter association for his paper on the Evolution of the Steam Turbine in the Textile Industry.

Managers, 1918-1921

Charles L. Newcomb

Charles Leonard Newcomb, a Manager of the Society, was born in West Willington, Conn., August 7, 1854. His early life was divided between working in a glass factory during the winter months and on a farm during the summer months, and he had slight opportunity for attending the district school of the locality.

He was at an early age employed with the Hall Thread Co., South Willington, Conn. Later he was an apprentice in the Murless Foundry and at the Seinor Machine Shop and afterwards was employed as a machinist with the Rock Mfg. Co., Rockville, Conn.

In 1874 he entered the employ of Pratt & Whitney Co., Hartford, Conn. In 1880 he graduated from the Worcester Polytechnic Institute with the degree of B. S. and later was employed as superintendent of the American Electric Light Co., New Britain, Conn., which afterwards became the Thomson-Houston Electric Co. of Lynn, Mass.

In 1881 he entered the employ of Deane Steam Pump Company of Holyoke, Mass., as superintendent, and was made general-manager when the company was acquired in 1899 by the International Steam Pump Company. He continued in the service of this company in the same capacity after it was merged into the Worthington Pump & Machinery Corporation in May 1916.

Mr. Newcomb as a mechanical engineer specialized in steam and hydraulic engineering and has been a very active factor in

the upbuilding of the Deane Works. During his residence in Holyoke, he acted as consulting engineer for various manufacturers of the State, and was employed as an expert in various lines of engineering work. He has been associated with many valuations of plants. Especially of note is the case of the Holyoke Water Power Company, Gas and Electric Branch, which was taken over as a municipal plant by the city of Holyoke.

Mr. Newcomb has been active in the upbuilding of Holyoke and identified with its municipal affairs in various ways. He assisted in organizing the National Founders' Association in January, 1898, and he was elected its first vice-president. He was also a member of a committee of three who drew up the constitution and by-laws adopted by this association. He was also a member of the committee which drew up the constitution and by-laws of the National Metal Trades Association, organized during 1899, and was its first vice-president. He was elected to membership in this Society in 1883.

Frank O. Wells

Frank O. Wells was born in Shelburne Falls, Mass., January 6, 1855, and went to school there. In 1874 he entered the employ of the Wiley & Russell Mfg. Co., as a workman and five years later organized with his brother, Frederick E. Wells, the Wells Brothers Company. From this small beginning the firm grew into one of the leading tap and die industries of the country, later merging with the Wiley & Russell Mfg. Co., and forming the present Greenfield Tap & Die Corporation, Greenfield, Mass., of which Mr. Wells is president.

Mr. Wells has been associated with many public interests. He was one of the first to study the problem of making gages and to manufacture them on a war basis. Long before war was declared by the United States he pressed the necessity of the Government's making provision for special tools, gages and fixtures in order that contracts for ammunition might be placed immediately when the need arose.

In 1903 Mr. Wells became a member of the Society. He is on the Society's Committee for the Standardization of Screw Thread Tolerances, and has also been appointed a member of the National Screw Thread Commission as one of the Society's representatives.

Charles Russ Richards

Charles Russ Richards was born at Clarks Hill, Ind., March 23, 1871. He was educated in the public schools of Indiana and at Purdue University, where he received the degree of Bachelor of Mechanical Engineering in 1890, and the degree of Mechanical Engineer in 1891. In 1895 he received the degree of Master of Mechanical Engineering from Cornell University.

While Dean Richards has served in various capacities as a consulting engineer, he has devoted most of his attention to the problems of engineering education.

In 1891 he was instructor in mechanical engineering at the Colorado Agricultural College; in 1892 adjunct professor at the University of Nebraska where he continued as professor of mechanical engineering up to 1911. In 1909 he became the first Dean of the State College of Engineering at this University. In September 1911 he accepted the professorship of mechanical engineering at the University of Illinois, and from June 1913 to September 1915 he served as Acting Dean of the College of Engineering and Director of the Engineering Experiment Station at this University. In March, 1917, after Dean W. F. M. Goss had resigned, Professor Richards was appointed as his successor.

At the University of Illinois, under the general direction of Dean Richards, the work in the college shops has been completely reorganized so that they have been converted into laboratories to provide instruction in the principles of industrial management in the art of manufacturing, to illustrate the effect of the shop processes on the materials of instruction, and to do experimental and research work in connection with the cutting of metals and in the general field of engineering production. It is felt that the methods employed in these laboratories constitute a distinct contribution to the field of engineering education.

Dean Richards has served as consulting engineer in connection with power-plant and water-works problems and the appraisal of public utilities. He has been interested in engineering research relating to fuels, steam engineering, air compression, and gas-power engineering.

He was elected to membership in the Society in 1892. He is chairman of the Bureau of Mines Sub-committee on Fuels which was appointed by the Society, and is a member of the Society's Committee on Local Sections and of the Fuel Division of the Power Test Committee. He is also a representative of this Society on the Engineering Council's Committee on Fuel Conservation, which was appointed to coöperate with the United States Fuel Administration and the Bureau of Mines during the war, and he is a member of the Special War Committee of the Society for the Promotion of Engineering Education and the representative of this Society on the Joint Committee on Engineering Education. He is also a member of the Technical Committee on Coal for Gas, By-Products and Public Utilities appointed by Governor Frank O. Lowden of Illinois, to study problems connected with the utilization of central-western bituminous coal in the manufacture of illuminating gas.

Council Notes

At the meeting of the Council on December 3, 1918, preceding the 39th Annual Meeting, the following members were present: President Charles T. Main presiding, Spencer Miller, William H. Wiley, *Treasurer*, Ira N. Hollis, John A. Stevens, F. N. Bushnell, James Hartness, R. H. Fernald, Arthur M. Greene, Jr., John A. Brashear, Jesse M. Smith, John Hunter, C. T. Plunkett, D. S. Jacobus, Worcester R. Warner, and the Chairman of the Committees on Administration, George A. Orrok, L. P. Alford, Hosea Webster, Henry Hess, Chairman of the Standardization Committee, Calvin W. Rice, *Secretary*, and by invitation, F. R. Low, representing the Power Test Committee.

Special Orders

Honorary Membership. The Secretary read the report of Tellers on the ballots for Honorary Membership of Charles M. Schwab and Orville Wright, and the President declared them elected.

F. R. Hutton Memorial. Jesse M. Smith, for the Committee on a Memorial to the late Prof. F. R. Hutton, presented a design of plaque by Victor D. Brenner, which was accepted and the committee charged to complete the memorial.

Business from the President

Fuel Conservation. It was voted to appoint a committee to consider the preservation of the fuel conservation data collected by the U. S. Fuel Administration.

Executive Committee

Paris Engineering Congress. The appointment was made of President Main, to represent the Society at the Engineering Congress called by the Société des Ingénieurs Civils de France, to be held in Paris in December 1918.

Standing Committees

Research. An additional appropriation was granted this committee for the use of the Sub-Committees on Flow Meters and Bearing Metals.

Special Committees

Aims and Organization. Mr. Alford, representing the Committee on Aims and Organization, reported the resolutions which are published elsewhere in this issue.

War Industries Readjustment. The report of the Chairman of this committee was received.

Administration. This committee was discharged with thanks and its work of administration of the Society's offices placed in the hands of the Finance Committee.

Engineering Resources. In consistency with the action of the Engineering Council, discharging its Committee on American Engineering Service, this committee was discharged with thanks.

Professional Committees

Boiler Code. Upon recommendation of the entire Boiler Code Committee, the publication of the Revised Code was authorized.

The appointment of S. W. Miller on the Sub-Committee on Welding of the Boiler Code Committee was approved, as also was the appointment of John C. McCabe, Chairman, E. C. Fisher and John R. Allen, as a sub-committee to obtain data on the strength of cast-iron sections in boilers.

Power Test Code Committee. The Advisory Board and the Main Committee of the Power Test Code Committee were combined as one Board, and the following sub-committees were approved:

1. General Instructions
2. Definitions and Values
3. Fuels
4. Boilers
5. Steam Engines
6. Steam Turbines
7. Displacement Pumps
8. Centrifugal Pumps
9. Displacement Compressors and Blowers
10. Centrifugal and Turbo-Compressors
11. Complete Steam Power Plants
12. Condenser Units and Feedwater Heaters
13. Refrigerating Machines and Plants
14. Evaporating Apparatus
15. Locomotives
16. Gas Producers
17. Gas and Oil Engines

F. R. Low was appointed Chairman of the Power Test Code Committee.

Refrigeration. The Committee on a Standard Tonnage Basis for Refrigeration was discharged with thanks.

Appointments. Joseph Harrington as a member of the Committee on Feed Water Heaters, John A. Stevens as Acting-Chairman of the Committee on Cost of Electric Power, and C. E. LePage as Honorary Vice-President to represent the Society at the meeting of the Society for Promotion of Engineering Education, Boston, Mass., December 5 and 6.

War Tribute of Engineers. It was voted to appoint a committee to consider a suitable memorial as the Engineers' tribute to those members who lost their lives in the War.

Award of Merit

The establishment of an Order of Merit was approved, and the appointment of a committee to draw up rules and requirements ordered. This Order will be awarded, under vote of the Council, to persons who fulfill the requirements, and who by exceptional genius and accomplishment of engineering results have benefited mankind.

Retirement of the President

The Council gave a rising vote of thanks to the retiring President, Charles T. Main, for his devoted attention to the duties of his office during the past year, together with an expression of the best wishes for a successful and pleasureable outcome both professionally and personally in his trip to France.

Calvin W. Rice,
Secretary.

The first meeting of the Council for the year 1918-1919 was held on adjournment of the Annual Meeting on Friday, December 6, 1918. Present: C. T. Plunkett, retiring Vice-President, who presented the new President, Mortimer E. Cooley, the new Vice-Presidents, F. R. Low, Henry B. Sargent, John A. Stevens; the new Managers, Charles L. Newcomb, F. O. Wells, Charles Russ Richards; others present were Spencer Miller, D. Robert Yarnall, Ira N. Hollis, D. S. Jacobus, Jesse M. Smith, *Chairman Committee on Constitution and By-Laws*, George M. Forrest, *Chairman Finance Committee*, Hosea Webster, *Chairman Membership Committee*, and Calvin W. Rice, *Secretary*.

Special Orders

A cable was sent to Past-President Charles T. Main, en route to France as the representative of the Society at the French Engineering Congress.

President Cooley was asked to represent the Council and convey a message of congratulation to Past-President Robert W. Hunt on the occasion of the celebration of his eightieth birthday.

Standing Committees of Administration

Local Sections. A resolution from the conference of Local Sections delegates assembled at the Annual Meeting, recommending that the Mid-Western Sections participate in the preparation of the professional program for the next Spring Meeting was referred to the Committee on Meetings and Program.

Washington Section. Spencer Miller, Vice-President, and the Secretary were delegated to represent the Council at a get-together meeting of the Washington members on December 9, and to give expression to the appreciation of the Council for the splendid work which Washington engineers had contributed in connection with the war.

Field Secretary. On account of the rapid growth of the Sections movement in the Society, and to provide a close contact between the local sections and headquarters, the appointment of a Field Secretary was authorized.

Standing Committees

Research Committee. Communications concerning (1) research on fatigue of metals, (2) approval of plans of the committee to issue a questionnaire, (3) appropriations for the Sub-Committee on Flow Meters—now designated Fluid Meters and (4) appropriation for the Committee on Bearing Metals, were received and favorable action taken.

Professional Committees

Power Test Code. A. M. Hunt was appointed a member of the Committee, to fill the vacancy caused by the death of Wm. Kent.

Boiler Code. The Council recorded its congratulations and sincere appreciation of the splendid work which has been accomplished by the Boiler Code Committee, and the ever-increasing and far-reaching value of the Code.

Special Committees

Aims and Organization. Resolutions recommending a committee on coöperation of employer and employee were favorably received.

Appointments

I. E. Moultrop was reappointed to represent this Society on the Board of Trustees of United Engineering Society.

W. F. M. Goss was nominated as the representative of this Society on The Engineering Foundation.

John A. Brashear was elected as the representative of this Society on the John Fritz Medal Board of Award.

Adjournment was taken to meet Friday, January 17, 1919, in New York.

Calvin W. Rice,
Secretary.

AMONG THE LOCAL SECTIONS

THE Annual Conference of Local Sections delegates was held in New York on Tuesday, December 3, in connection with the Annual Meeting. All of the twenty-two sections were represented.

The conference was opened by Mr. D. R. Yarnall, *Chairman* of the Committee on Local Sections, who reviewed the annual report of the national committee as published in the December issue of THE JOURNAL. Following this each of the delegates was asked to hand in his written report, and to supplement it by oral remarks. The reports will be summarized in the February issue.

Some valuable observations and suggestions were made in the oral discussion: for example, the delegate from Milwaukee suggested that the Society publish a handbook containing technical data including actions and reports of the various committees of the Society upon standards and standarization, together with the logarithmic tables and other mathematical data.

The member from Baltimore suggested that if the national society submitted to the sections very definite and limited questions for discussion the results would be of great value. There are many subjects of legislation in connection with the education of engineers, ethical standards of engineering, etc., on which such definite questions could be founded.

Chicago suggested coöperation with the New York office in the matter of reëmployment of engineers who come back from the service.

Cleveland and Indianapolis recommended that the mid-western sections be permitted to participate in the preparation for the professional program for the next Spring Meeting, and this recommendation was made the subject of resolutions which were later presented to the Council.

The delegate from Los Angeles reported a plan for the publication of experimental data obtained in several universities in that Section. He suggested that the Society's Research and Standardization Committees outline subjects upon which information was required.

The New York delegate called attention to some of the problems which confront a section of over 2200 members. The largest of these is so to organize the section that the men at large know each other and will attend the meetings. He suggested interchange of meeting notices between sections to invite traveling members to become interested in section activities.

The delegate from Ontario requested information on how to keep up the interest in a small section in a distant place, and said he would like to hear discussion on the things which were found vital and had made meetings a success.

The delegate from St. Louis suggested that standards be outlined showing the sections just what they could do in the matter of members, meetings, papers, research, standardization, etc.

A running account of the written and verbal reports of the delegates is being prepared, and will be mailed out to the Sections and upon request to anyone else interested.

Following the presentation of these reports, the conference took up a discussion of two important matters respecting the Sections Committee—the proposed change in the Constitution providing for the regular Nominating Committee to be elected by the voting membership; and the activities of the national Committee on Increase of Membership. The discussion on the former subject culminated in a resolution to the Council that it was the sense of the Conference that the regular Nominating Committee should be composed of one representative from each Section and seven members at large, to be appointed by the Council. Mr. Jesse M. Smith, *Chairman* of the Constitution and By-Laws Committee, was present during this discussion.

Professor Arthur L. Williston, *Chairman* of the Increase of Membership Committee was present by invitation, and expressed his interest in seeing how universal is the sentiment of confidence in the Local Sections, and the belief that the sections are going to play a larger and more important part in the life of the Society. He thought this was true, without question. He considered that the life and strength of the Society depends on the quality and enthusiasm of the men constantly coming into the organization, and there is no way in which men who have the welfare of the Society at heart can serve it more effectively or permanently than by interesting the right kind of engineers to show the same interest and devotion to the Society that they themselves have.

It seemed to him that the executive committees of the sections and the sub-committees coöperating with them were by far the most important part of the Increase of Membership organization.

A significant note which extended through the whole discussion was the possibility of developing through the Local Sections the relation of the engineer to the community; for example, the delegate from Atlanta called attention to the Engineering Committee in that city appointed each year by the mayor to advise the civic administration on engineering problems. This committee is made up of a representative from each of the four national societies, and the Atlanta Section is represented.

He considered it a departure from ordinary political practice, and undoubtedly a step forward. He said it might mean the recognition of the need and usefulness of engineering ability in the close coöperation with political administration whereby the principle of service may become more and more a tangible reality and less an academic ideal.

"To this end," he concluded, "the membership of the Atlanta Section is constantly striving and we bespeak for ourselves the continuation of the close coöperation and friendly advice on the part of the Local Sections Committee and the membership of the Society."

Washington Section to be Organized

WHAT promises to become an important section of the Society is in process of formation at Washington, D. C. The preliminary meeting for the organization was held at Washington, December 9, 1918, following the Annual Meeting in New York. This was called by a temporary committee consisting of Lieut.-Col. John J. Swan, Major A. D. Blake, George A. Weschler, H. L. Whittemore and Ernest Hartford.

In the afternoon an excursion was arranged to the Bureau of Standards in which about 60 participated. Supper was later enjoyed at Cushman's restaurant, following which there were several addresses, an exhibit and motion pictures of the Browning gun, and a general discussion of the question of the Washington section. A petition to the Council for a local section was signed and the following Local Committee chosen: S. W. Stratton, *Chairman;* George A. Weschler, Secretary; Major J. Henry Klinck, Arthur E. Johnson and Herbert L. Whittemore.

Officials of the Society present were Spencer Miller, Vice-President; William H. Wiley, Treasurer, and Calvin W. Rice, Secretary. Mr. Miller was delegated by the Council to attend as representative and to convey its greetings.

Mr. Rice first spoke, giving practical suggestions from his experience with regard to the organization of a section of the Society. Mr. Miller expressed the pleasure of the Council at the prospect of a Washington section as it was realized how fully the Washington members had contributed to the work of the Government during the war. He said that the war had distinctly shown what a people can do that is bound together with a spirit of righteousness and coöperation, that it can perform miracles if it wants to, and that he hoped that the Washington section would likewise bear splendid fruit in papers that would enrich the Transactions of the Society. He tendered the greetings of the Council and congratulated the section on its large initial attendance.

ARMY RESEARCH WORK

Major O. B. Zimmerman, of the Research and Development Branch of the Army Staff, explained the nature of the work of his branch, covering the supply, purchase and inspection of mobile army equipment, and later imparted some interesting in-

formation regarding the newly-announced substitute for gasoline, named "Liberty Fuel."

Mobile army equipment supplies, said Major Zimmerman, covered that which was used by the engineers in the field of operations.

Equipment and supplies were needed in vast quantities beyond the possibility of using available military equipment and it was therefore necessary to meet the demand by supplying this equipment which was designed and built primarily for commercial needs.

As viewed from the standpoint of the military requirements it was recognized that commercial equipment had certain characteristic deficiencies which were not evident when viewed from peace requirements.

The mention of a few of these characteristics will illustrate the work which naturally fell to the lot of the Research and Development Division and to similar bodies in the Army, where the characteristics were such as to require alterations in order to adapt the apparatus to the needs of the Army, the changes were made with great care so as not to cause too much delay in manufacture.

Portability required great attention to permit frequent and quick changes in location in the field. Much commercial equipment had not received attention from this point of view. Both weight and volume were likewise affected.

Efficiency of motive power was required to the greatest practical extent to avoid carrying unnecessary lubricants and fuels. The majority of appliances in the smaller units were not developed with marked attention to best of materials, efficiency or economy and their commercial ratings were often widely at variance with delivered capacities. Shop test methods were often sadly in need of standardization and Army methods of rating and testing had to be devised.

Enclosure against exposure, while sufficient under normal commercial conditions, was often not sufficient for protection in the field against mud, dust, rain, sun and cold and hence the alterations were necessary to cover these conditions.

These few points will suffice to indicate the general nature of problems connected with equipment serving the purposes of water supply, forestry, road construction, shops, transport, quarrying, crushing, construction, etc.

A considerable group of officers were giving efficient and effective work along these lines and when possible to recount in detail what they accomplished their work will be most gratifying to the engineering profession.

One problem only will emphasize the activities along chemical and physical chemical lines namely that of developing "Liberty Fuel."

Liberty Fuel

This novel fuel consists of over 80 per cent of kerosene, the remainder being chemicals freely obtainable in quantity. This fuel was compounded by officers in the General Engineer Depot, Research Division (which now is operating as a part of the Purchase, Storage and Traffic Division, General Staff) with the object of meeting the anticipated shortage of motor fuel for war purposes planned for the campaign of 1919. The laboratory work on this fuel was completed at the Bureau of Standards. The object was to transform the heavier hydrocarbon oils into lighter ones so that they could be carbureted like gasoline, by a process different from the well-known Burton and Rittman processes. The complete treatment used in the production of "Liberty Fuel" was not to be disclosed until the rights and privileges of the Government and interested individuals were definitely fixed. He said that at the present time the cost of the new fuel should be less than that of gasoline. The process of manufacture was simple and similar to that produced by fractional distillation of native oils. Various grades of oils could be turned out suitable for all types of internal-combustion engines. He said that to Capt. E. C. Weisgerber was due a great deal of the credit for solving the problem by devising a new and independent chemical process. The new fuel had undergone a series of very exhaustive tests in all conceivable types of military and other power engines. The power developed was measured and declared by the Bureau of Standards to be equal in all respects to the results obtained with commercial gasoline. The fuel could be used in any engine built for gasoline or kerosene. The temperature of the engine was lower than with gasoline, which facilitated better lubrication and longer life of the engine.

Although the weight per gallon of the new fuel was greater in the ratio of 7.07 lb. for "Liberty Fuel" against 5.93 lb. for export aviation gasoline, the heat units per gallon were as 124,800 to 112,300 for the gasoline. It was reported that the thermal efficiency was higher in the new fuel, and that the horsepower developed also was greater. Airplanes could remain longer in the air for an equivalent quantity of fuel. Motorcycles showed a marked increase in mileage over that when gasoline was used. Also he said that the superiority of the new fuel was attributed to the lesser heat lost in exhaust and cooling jacket, leaving more heat available for useful transformation into power.

Major Zimmerman thought that this successful solution of the problem of a substitute fuel was an excellent example of the value of coöperation between the War Department and the Bureau of Standards, and that without this valuable assistance the solution of the problem would have been delayed, and he therefore decided to publicly express the thanks of the Department to Dr. Stratton and his able assistants for their coöperation, and his hope that such coöperation would always exist.

Bureau of Standards

Dr. S. W. Stratton, Director of the Bureau of Standards then told the meeting something of the work being done at the Bureau, of its standardization work, of tests being made and specifications written for all sorts of materials used in the industries and by the various Departments of the Government. During the war at least 95 per cent of the Bureau's work had had some connection with military departments. He related how master gages were calibrated by means of light waves, how in spectroscopy plates were stained so as to be more sensitive to the red and longer waves, which plates were very useful in aviation photography. That similar improvements were made in electrical sound ranging. Reference was also made to the airplane motor building that had been erected on the grounds of the Bureau to test the performance of motors under conditions duplicating those of an airplane 25,000 ft. above ground, a 25-ton refrigerating plant being used in this case to cool the air which was at a pressure of only 16 in. of mercury.

Dr. Stratton explained also how the heat resistance of refractories was improved, so that we did not have to depend any longer on the supply from abroad, and were able to make spark plugs that would be durable. The crucibles used in making glass had to be perfected in the same way, with the result that glass parts were finally available at a cost of $9 apiece against $55 for the imported article. That in fact it was believed that these various discoveries in glass manufacture made this country independent of European sources of supply. Another material which was perfected with the assistance of the Bureau was cotton, which was so treated as to take the place of linen in airplane construction, after the supply of linen had become low. In closing Dr. Stratton recalled the pleasant relations established with all military departments, invention boards, etc., and was glad that the Bureau had been able to render services to all departments that had called upon it for scientific assistance.

General Remarks

Major Wiley spoke briefly of the six years which he spent in Congress as one of the few engineers that have been members of that body. He thought Congress did not treat Washington as well as it should, and it did not understand scientific men. He said the Washington Society of Engineers had done good work, and he felt sure that this new Washington section would have an equally brilliant future. That this organization was something they had wanted for a long time, to be able to reach Congress when necessary.

Lieut.-Col. Scrugham reviewed briefly the prominent part taken by members of the A.S.M.E. in the conduct of war operations. He said the machine-tool business had jumped from about 50 millions to 500 millions during the last year and that it was surprising that the Ordnance Department organization stood the strain as well as it did.

Meetings of Sections

ATLANTA SECTION

The Local Section had a very good attendance at its regular monthly meeting held Tuesday, November 26, in the Lecture Room of the Carnegie Library.

The meeting was given over to the discussion of local affairs, and also the organization and possibilities of the proposed American Engineering Society. The members also expressed themselves in regard to the business to come before the meeting of the Committee on Aims and Organization, in order that our delegates would have the benefit of the members' views.

W. J. NEVILLE,
Secretary.

BALTIMORE SECTION

The first fall meeting of the Baltimore Section was held at the Engineers' Club on November 20. The first paper of the evening was read by A. E. Walden, Mem.Am.Soc.M.E., on The Design of Hopper Bottoms for Coal Bins. He stated that he had found in his experience that frequently the cost of bins was unduly high on account of the heavy steel called for in the hopper bottom and its supports. The effect of dropping loads from grab buckets on the hopper bottom was discussed. Mr. Walden then proceeded to analyze the forces present and showed how to determine the stresses in the bottom by graphical methods. The effect of supporting studs and girders was also discussed. The angle of the bottom must be sharp enough to prevent arching. The down spout should be of No. 10 or No. 12 gage iron with vertical seam. Spiral riveted seams retard the coal flow. The bottoms are usually lined with concrete to provide a wearing surface that can be readily renewed. The use of reinforcing plates and angle stiffeners was also discussed.

In the discussion which followed, attention was called to the reinforced concrete bunker of catenary form. One objection to this was the banking of coal between openings.

The second paper of the evening was on Marine Practice in Valves and Piping by A. G. Christie, Mem.Am.Soc.M.E. It consisted of a series of comments on certain marine practices as seen from the viewpoint of a central station man. The effect of various factors on marine practice was noted and a discussion of present practice followed. The author made a strong plea for standardization in marine valves. The use of steel piping on shipboard was also discussed.

In the discussion which followed the following subjects were treated: the expansion of steel bends, the galvanizing of piping and other means of preventing corrosion and also valves for superheat.

A. G. CHRISTIE,
Secretary.

CHICAGO SECTION

The Chicago Section of the A.S.M.E. and the Mechanical Section of the Western Society of Engineers held the first dinner meeting of the season in the Red Room of the Hotel La Salle Friday, December 13. The address of the evening was given by D. L. Derrom, of Winslow Brothers Company, on Shell Manufacture. Mr. Derrom has had extensive experience in munitions manufacture in Canada as well as here, and is a recognized expert on the subject. The address was illustrated with lantern slides showing the processes and with moving pictures of the operations.

A. L. RICE,
Secretary.

CINCINNATI SECTION

A joint meeting of the Cincinnati Section and the Engineers' Club was held in the club rooms on November 21, the subject being A Discussion of the Readjustment of Industries to Peace Conditions.

A. J. Baker, Mem.Am.Soc.M.E., and also a member of the Machine Tool Section of the War Industries Board, opened the discussion by giving some of his experiences as a member of that Board. Mr. Baker also spoke of the tremendous expansion in the building of machine tools in England and stated that the United States would have to expect very strong competition in the building of machine tools from that source. He also gave some of the labor costs in England.

Professor Magee, of the Department of Economics, of the University of Cincinnati, then spoke of the conditions that obtained immediately after the Civil War and contrasted those with the conditions that are likely to obtain from now on.

JOHN T. FAIG,
Secretary.

CLEVELAND SECTION

Our newly-organized Cleveland Section took an important initiative in a special meeting called for Friday, November 29, at the Cleveland Engineering Society rooms, to discuss and recommend a plan whereby the various branches of engineering may be united under one head both nationally and locally.

This suggested plan of coördination has since been received at headquarters and referred to the Council, which voted to invite the Cleveland Section to send three representatives to its meeting in January to present the case to them.

J. H. HERRON,
Secretary.

ERIE SECTION

The Erie Section held a meeting at the Shriners Club on November 25, at which E. J. Armstrong, Mem.Am.Soc.M.E., of the Ball Engine Company, delivered an address on The Glacial History of Lake Erie.

The address treated of the working hypothesis now generally accepted regarding causes of diminished temperature making glacial conditions possible. Three distinct glacial periods of which there is evidence were discussed. Mr. Armstrong pointed out on maps the areas of successive great lake basins and outlets to the ocean prior to the present St. Lawrence River, stating apparent reasons for variations in the size of the gorge cut by the Niagara River and the probable rate of erosion as indicated by United States surveys.

M. W. SHERWOOD,
Chairman.

ONTARIO SECTION

A meeting of the Section was held at the Engineers' Club Friday evening, November 29. An address on The Main Pumping Station of the Toronto Water Works was given by John Milne, Mechanical Engineer, of the Department of Works. The lecture was illustrated by slides of much interest.

C. B. HAMILTON, JR.,
Secretary.

PROVIDENCE ENGINEERING SOCIETY

The Municipal Section held a meeting in the Society's rooms on November 26, at which an address was delivered by Harlow C. Clark of New York, Editor of *Aera*, the official magazine of the American Electric Railway Association.

The subject of the address was The Relation of Electric Street Railways to Municipalities and the Future of Electric Railways.

The Machine Shop Section held a meeting on December 10 which was addressed by George H. North, Superintendent of the Cartridge Case Plant. Mr. North spoke on The Manufacture of Cartridge Cases, describing the tools, equipment and processes. An interesting exhibit illustrating the various operations was shown.

On December 27 the Chemical Section held a meeting in the Society rooms. The speaker of the evening was Walter M. Russell, Superintendent of Manufacturing at the Providence Gas Company, who delivered an address on "Recovery of Light Oil Products at the Providence Gas Company."

W. H. MacKay of the Emergency Fleet Corporation, addressed the Society on December 17, the subject being Marine Engineering and Up-to-Date Methods of Repairing Ships.

W. A. KENNEDY,
Secretary.

SAN FRANCISCO SECTION

The first of a series of meetings planned began with an after-luncheon meeting at the Engineers' Club on Monday, December 16, where a short paper was read on The Use of Pulverized Coal by M. C. M. Hatch. Chief Engineer of the Locomotive Pulverized Fuel Company of New York.

On December 19 the Section held a meeting at the Engineers' Club, the subject being Why is the Internal Combustion Engine not Used More Extensively for Marine Propulsion?

J. H. Hanson, President of the Scandia Pacific Oil Engine Company, read a short paper on this subject, illustrated by about forty lantern slides, covering the history and development of the Diesel engine, and showing some of the more recent installations on ocean-going vessels.

George A. Dow, President of the Dow Pump & Diesel Engine Company, read a paper on the Diesel Oil Engines on board the Motorship *Libby Maine*.

A paper was also read by Bruce Lloyd, Marine Engineer for the Concrete Ship Section of the Emergency Fleet Corporation, which covered the attitude of ship owners toward the use of the internal combustion engine as power for the propulsion of ships, together with some remarks about the difficulties that have been encountered in the installations which have been under his personal supervision, and also, descriptions of the performances of ships that have been equipped with these engines.

GEORGE L. HURST,
Secretary.

NECROLOGY

DIED IN THE SERVICE

Lawrence H. Bertsch, Captain, Engineering Division, Ordnance Department, U. S. Army.

William J. Plank, Cadet, Air Service, U. S. Army.

WILLIAM SICKLES ACKERMAN

William S. Ackerman, engineer and architect, died on November 11 of heart failure, after a brief illness. He was engaged at the time in the service of the Ordnance Department, U. S. A., as supervising engineer of the Government Carbocoal plant being erected at Russell, near Clinchfield, Va.

Mr. Ackerman was born in November, 1868, in Paterson, N. J. He received his technical education at the Stevens Institute of Technology, where he graduated in 1891, with the degree of M.E. His earlier work was in the West, where he acted as Colorado agent for the Ingersoll-Sargent Drill Co. as draftsman and mechanical engineer for the Standard Smelting and Refining Co. of Durango, Colo., and as assistant superintendent of the Pelican-Dives Mining Company at Silver Plume, Colo. From 1893 to 1897 he was chief engineer of the National Lead Co. He then formed the partnership of Ackerman & Ross, Engineers and Architects, which in 1902, on the retirement of Mr. Ross, became Ackerman & Partridge. The work done by these firms covered nearly every branch of the profession. It included: Carnegie libraries at Washington, D. C., Atlanta, Ga., San Diego, Cal., Port Jervis, N. Y., and Bucknell University, Lewiston, Penn., Engineering and Chemical laboratories at Stevens Institute, etc., court houses, banks, office buildings, schools and factories in

WILLIAM S. ACKERMAN

many states. Perhaps the most notable of these from a scientific standpoint was the Morton Memorial Laboratory at Stevens Institute of Technology. Mr. Ackerman made a special study of the requirements of a chemical laboratory and put forward a design containing so many new and admirable features that it has served as a model for many of the more recent laboratories.

On the dissolution of the firm of Ackerman & Partridge in 1905, Mr. Ackerman went into consulting practice in mill construction and power plants and in 1907 became a member of the Passaic Valley Surveys Commission, which he served in the capacity of secretary, until 1913, when he returned to private practice. In 1916 he went with the O'Rourke Engineering Construction Company as expert in patent litigation. While so engaged he offered his services to the Army Ordnance Department, and by a singular coincidence, died in service at the plant in Virginia on the day the Armistice was declared.

Mr. Ackerman was a member of the New Jersey chapter of the American Institute of Architects, and the Alumni Association of the Stevens Institute of Technology, of which he was president in 1902. He was a former member of the American Institute of Mining Engineers. He became a member of the Society in 1891.

LAWRENCE HOWARD BERTSCH

Lawrence H. Bertsch, Captain in the Engineering Division of the Ordnance Department, U. S. Army, died at the Walter Reid Hospital, Washington, D. C., on Sunday, October 13, after a four-days' illness of influenza followed by pneumonia.

Captain Bertsch was born in Cambridge City, Ind., on October 18, 1879. He attended Earlham College, Richmond, Ind., from 1898 to 1901. In 1902 he received his A. B. degree from Indiana University and the following year entered the University of Michigan, from which he was graduated with the degree of M. E. in 1907. From then until his enlistment in June 1918 in the U. S. Army he was associated with Bertsch & Co., Cambridge City, Ind., manufacturers

LAWRENCE H. BERTSCH

of shears, punches, rolls and presses. He served in various capacities in office and plant, including those of sales manager, superintendent, general manager, chief engineer and finally as vice-president of the company.

He became a member of the Society in 1918. He was also a member of the Engineering Society of Indiana.

EMIL BREZINSKY

Emil Brezinsky was born in New York City on March 4, 1867. He was educated in the public schools of Minneapolis and attended the University of Minnesota. He served his apprenticeship with the Wilford Mfg. Co., Minneapolis. From 1898 to 1907 he was connected with the Allis-Chalmers Co., Milwaukee, as draftsman, and later as chief draftsman on mill construction, power-plant work and in designing and superintending of construction work. He was next associated with the Minneapolis Steel & Machinery Co. in the engine and mechanical department as chief draftsman and assistant engineer; he also designed and developed gas and steam engines, and from 1910 to 1912 was acting chief engineer of the company.

Mr. Brezinsky spent a number of years in Russia representing the Allis-Chalmers Co., and later the International Engineering & Trading Co. At the time of his death in February 1918 he was connected with the Strong-Scott Manufacturing Co., Minneapolis.

Mr. Brezinsky became a member of the Society in 1912.

HAROLD H. HILL

Harold H. Hill was born in 1875, in Detroit, Mich. He was graduated from Cornell University in 1897 with the degree of M. E. His apprenticeship was spent with the Akron, Bedford and Cleveland Railroad Co., Cuyahoga Falls, Ohio. He obtained his drawing-room and shop experience with the American Ball Bearing Co., Cleveland, Ohio. He was next employed by E. H. Jones & Co., Cleveland, as erecting engineer, leaving that firm to represent in Cleveland the B. F. Sturtevant Co., of Boston, Mass.

In 1901 he became associated with the Eric City Iron Works, Cleveland, as mechanical engineer and district sales agent, acting also as contracting engineer. At the time of his death, October 28,

1917, he was holding the position of district sales manager of the company.

Mr. Hill became an associate of the Society in 1904 and a member in 1915.

JOHN S. HUNTER

John S. Hunter was morn in Manchester, Conn., on June 14, 1834. He was educated in Rockville and in the public schools of Pennsylvania. He served his apprenticeship with the Woodruff & Beach Iron Works, Hartford.

For eleven years he was in charge of the Hartford Pumping Station, later becoming a member of the firm of Hunter & Sanford, machinists. Seven years later the Hartford Foundry and Machine Co. was organized and Mr. Hunter was chosen as president. During his connection with the company he built the largest pumping engine in the world, which was installed for the St. Louis Water Works in 1873. For a number of years Mr. Hunter was with the Henry R. Worthington Co., New York, erecting steam pumps for city water works. He was appointed a member of the Board of Water Commissioners of Hartford in 1870 and served three years. By reappointment he became a member of the board again in 1894 and was president from 1895 to 1899. In 1904 he was appointed fire commissioner and served three years.

Mr. Hunter became a member of the Society in 1889. He died on May 7, 1918.

CADET WILLIAM J. PLANK

William J. Plank was born on November 1, 1887, in Jetmore, Kan. He was graduated from the University of Kansas in 1911 with the degree of A. B.; in 1913 he received his M. E. degree and shortly afterwards was appointed through Civil Service to the shops of the mechanical division of the Panama Canal Commission. His duties consisted of general drafting work dealing with construction equipment. He also acted as instructor in mechanical drawing to a class of about thirty apprentices. In April 1916 he was transferred to the planning department of the drafting room.

In the early part of 1918 he enlisted in the Air Service of the Army and was assigned to the School of Military Aeronautics, Austin, Tex., and later transferred to the flying field at Sacramento, Cal.

Cadet Plank died on November 12, 1918, of pneumonia. He became a junior member of the Society in 1916.

GEORG GUSTAV ROHLIG

George G. Rohlig was born on May 7, 1872, in Eisenach, Thuringa, Germany. He came to this country when about sixteen years of age and started work in the Botany Worsted Mills, Passaic, N. J., returning to Europe a few years later. He studied in technical universities at Winterthur and Zurich, Switzerland, and at the Royal Polytechnic High School, Stuttgart, Germany, receiving his engineering degree and thereafter being associated for a period with Leipziger Wollkammerie, Hoboken les Anvers, Succursale, on work having to do with textile machines. His drafting-room experience he gained while with Kammgarnspinnerei, Stoehr & Co., Plagwitz-Leipzig, Germany. He served his apprenticeship in the woolen and worsted mills of Belgium and England, thus laying the foundation of his great technical knowledge in the milling industry.

Upon his return to this country he again became associated with the Botany Worsted Mills as assistant superintendent in charge of the manufacturing. He also assisted in the various enlargements of the mills and since 1903 was director and general superintendent of the company, holding this position at the time of his death, October 29, 1918.

Mr. Rohlig became a member of the Society in 1909.

HORACE MILLIKIN SMITH

Horace M. Smith was born on November 1, 1880, in Terre Haute, Ind., and received his early education there. He was graduated from St. Albans Military Academy and later attended Massachusetts Institute of Technology. He served an apprenticeship with the Niles Tools Works Co., Hamilton, Ohio, as draftsman and also with the American Soda Fountain Co. in the same capacity. In 1904 he became associated with the Liquid Carbonic Co., Chicago, Ill., as a designer and traveling erecting engineer and was advanced rapidly until in 1908 he was given full charge of the iron foundry, the brass foundry and the machine shops. At the time of his death he was chief engineer of the company.

Mr. Smith was an authority on all matters pertaining to the carbonated-drink and bottling industry and the inventor of several devices which have resulted in a practical revolution of that business.

Mr. Smith became a member of the Society in 1913. He died on November 12, 1918.

FLOYD G. TEN BROECK

Floyd G. Ten Broeck was born in Elmira, N. Y., on August 28, 1872, and received his early education in that city. Later he attended Cornell University and was graduated in 1895 with the degree of M. E. His first position was with the Osborn Engineering Co. and dealt with shop engineering. From 1897 to 1899 he was connected with Miliken Brothers and also with R. P. and J. H. Statts, where he obtained his drafting experience. In 1899 he became associated with Westinghouse, Church, Kerr & Co. in the design and erection of mills and power plants, leaving that firm to open private consulting offices in New York City in 1902. For the last sixteen years Mr. Ten Broeck was manager of the engineering department of the West Virginia Pulp & Paper Co., New York.

Mr. Ten Broeck became a member of the Society in 1903. He died on November 1, 1918.

SAMUEL F. TRIPP

Samuel F. Tripp was born in New Bedford, Mass., on November 14, 1866. He was educated in the public schools of New Bedford and later attended the New York evening schools and the Polytechnic Institute of Brooklyn. He also took a course in the International Correspondence Schools of Scranton, Pa.

At the age of eighteen he accompanied his father on a trip to California and while there entered the employ of the Arctic Whale Oil Co., where he worked for two years. His next position was with the Corliss Steam Engine Co., Providence, R. I., as erecting engineer, where he had charge of the installation of engines in the plant of the Waterbury Electric Light Co., Waterbury, Conn., and of repair work on engines in many cities of Rhode Island and Massachusetts. He then entered the employ of the Jones & Laughlin Co., Pittsburgh, Pa., and had charge of the erecting of shafting, being employed for about two years in various mills throughout New England. He was reëmployed by the Corliss Co. and placed in charge of erecting boilers, handling the installation of boilers in Elizabeth, N. J., New York and Baltimore.

In 1891 Mr. Tripp became associated with the Third Avenue Railroad Co., New York, and was put in charge of the erecting of the engines at the Sixty-fifth Street and Bayard Street power stations. In 1901 when the motive power of the Third Avenue System was changed from cable to underground electric the cable power stations were shut down and Mr. Tripp was transferred to the Ninety-sixth Street power station of the Metropolitan Street Railway Co. as engineer in charge. From April 1914 until the Ninety-sixth Street station was discontinued Mr. Tripp in addition to his duties as engineer of that plant was also employed to superintend mechanical construction work at the Seventy-fourth Street power station of the Interborough Rapid Transit Co., having charge of all mechanical equipment in connection with the 30,000-kw. turbines installed in that plant. At the time of his death, September 29, 1918, he was field engineer in charge of mechanical construction connected with the 60,000-kw. turbine now being constructed at Seventy-fourth Street.

Mr. Tripp was a member of the National Society of Stationary Engineers. He became an associate member of the Society in 1915.

PHILIP WALLIS

Philip Wallis was graduated from the Stevens Institute of Technology in 1879. He was first employed by the Clark Bridge Co. as draftsman. His next position was as instructor in mechanical drawing at the Maryland Institute Night School of Design. In the latter part of 1880 he was made assistant in the testing department of the Chicago, Burlington & Quincy Railroad and the following year became engineer of tests in charge of the physical laboratory of that company. In 1886 he became connected with the Long Island Railroad Co. as superintendent of equipment.

Mr. Wallis became a member of the Society in 1886. He died on March 3, 1918.

CHARLES SMITH WHITNEY

Charles S. Whitney was born on August 25, 1881, in North Attleboro, Mass. He received his early education in the public schools of Boston. His technical education he obtained through many years of intensive study by correspondence and through lectures.

He served an apprenticeship of two years with the Holtzer-Cabot Electrical Co., Brookline, Mass., as electrical machinist and draftsman. In 1899 he became assistant to the mechanical superintendent of the Massachusetts General Hospital, Boston. His next position was as construction foreman with the Elektron Manufacturing Co. In 1903 he became associated with the General Accident, Fire and Life Insurance Corporation as elevator inspector, and two years later became senior inspector. In 1912 he was appointed engineer in charge of inspection work and in 1914 became chief engineer in complete charge of all engineering work for the corporation. The following year he was made executive superintendent and at the time of his death, on October 31, 1918, was holding this position.

Mr. Whitney became an associate member of the Society in 1916.

ROLL OF HONOR

At the Annual Meeting was distributed a Roll of Honor of 1397 names of members in active service in the Great War, corrected to November 11, 1918, the date of the signing of the armistice. Since that date additional names have come to hand and are published below, together with those names appearing in the pamphlet but not as yet published in THE JOURNAL.

ADAMS, JAMES F., Captain, Inspection Division, Ordnance Department, U. S. Army.
AKERLOW, G. W., Captain, Quartermaster Corps, U. S. Army.
BANE, T. H., Colonel, Air Service, Military Aeronautics, U. S. Army.
BAYLIS, R. V., Lieutenant, Ordnance Department, U. S. Army.
BEROLSHEIMER, H., Second Lieutenant, Field Artillery, U. S. Army.
BLACK, JOHN S., Major, Ordnance Department, U. S. Army.
BLOHM, A. H., Second Lieutenant, Ordnance Department, U. S. Army; assigned to Ordnance Motor Instruction School, Raritan Arsenal, N. J.
BODENSTEIN, W. E., Second Lieutenant, Chemical Warfare Service, U. S. Army.
BRANDT, H. A., Lieutenant (Junior Grade), U. S. Naval Reserve Force.
BRECKENRIDGE, A. L., Chief Machinist's Mate, Mine Filling Depot, Construction Unit, U. S. Navy.
BROOM, B. A., First Lieutenant, Engineers' Corps, U. S. Army; assigned to Co. 7, Engineer Officers' Training School, Camp Humphreys, Va.
BUCKLEY, A. T., Chief Machinist's Mate, U. S. Naval Steam Engineering School, U. S. Naval Auxiliary.
BUTLER, ROLAND G., Second Lieutenant, Field Artillery, U. S. Army.
BUTTERFIELD, THOMAS E., Captain, Coast Artillery, U. S. Army.
CARSE, HERBERT E., Lieutenant, U. S. Naval Reserve Force.
CHERRINGTON, G. H., Major, Ordnance Department, U. S. Army.
CHRISTIE, W. T., Corporal, Engineers' Corps, U. S. Army; Engineer Officers' Training School, Camp Humphreys, Va.
COLLINS, S. W., Private, 322d Aero Squadron, Air Service, U. S. A.
CROSS, W. J., First Lieutenant, Engineers' Corps, U. S. Army; Engineer Officers' Training School, Camp Humphreys, Va.
CUNNINGHAM, F., First Lieuttnant, Quartermaster Corps, U. S. Army.
CUNNINGHAM, JAMES D., Second Lieutenant, Air Service (Production), U. S. Army.
CURTISS, C. R., Captain, Chemical Warfare Service, U. S. Army.
DEW, D. H., Second Lieutenant, Engineers' Corps, U. S. Army; assigned to Engineer Officers' Training School, Camp Humphreys, Va.
DOUGHTY, J. H., Captain, Tank Corps, American Expeditionary Forces, France.
DOWNES, N. W., First Lieutenant, Engineers' Corps, U. S. Army.
ELLIOTT, A. H., Captain, Engineers' Corps, U. S. Army.
FORD, WINTHROP D., Ensign, U. S. Navy; assigned to U. S. S. *Harrisburg*.
FOSTER, ROBERT J., Second Lieutenant, Chemical Warfare Section, U. S. Army.
FRANCIS, HARRIS S., Lieutenant, Ordnance Department, U. S. Army.
FREEMAN, H. S., Chief Machinist's Mate, U. S. Naval Reserve Force.
GLIMM, W. F., JR., Candidate; Engineer Officers' Training School, Camp Humphreys, Va.
GOODSPEED, C. B., Captain, Ordnance Department, American Expeditionary Forces, France.
HAB, HENRY A., JR., Captain, Chemical Warfare Service, U. S. Army.
HARDER, L. F., Captain, Co. C, 302d Engineers, 77th Division, American Expeditionary Forces, France.
HAZELTON, W. S., Captain, Ordnance Department, U. S. Army.
HILL, A. S., Captain, Production Division, Ordnance Department, U. S. Army.
HOLMBERG, A. W., Sergeant, Spruce Production Division, Air Service, Aircraft Production, U. S. Army.
HORN, N. E., Second Lieutenant, Air Service (Aeronautics), U. S. Army.
HOWELL, F. B., Engineering Division, Ordnance Department, U. S. Army.
IMBRIE, W. M., Captain, Engineers' Corps, U. S. Army; assigned to Camp Humphreys, Va.
JOHNSON, A. C., First Lieutenant, Engineering Division, Ordnance Department, U. S. Army.
JOHNSON, J. B., Field Artillery, U. S. Army; assigned to Central Officers' Training School, Camp Taylor, Ky.
JONES, W. T., Private, Coast Artillery Corps, U. S. Army.
KELLER, E. E., Motor truck engine (D); 39 623.
KLOTZ, HARRY J., Second Lieutenant, Air Service, Aeronautics, U. S. Army.
LADD, G. T., Lieutenant-Commander, Bureau of Ordnance, U. S. Naval Reserve Force.
LETELLIER, L. S., Second Lieutenant, Infantry, U. S. Army.
LEWIS, H. L., First Lieutenant, Ordnance Department, U. S. Army.
LOMAX, J. T., First Lieutenant, Chemical Warfare Service, U. S. Army.
LYNCH, THOMAS M., Major, Quartermaster Corps, U. S. Army.
MCLAREN, GEORGE C., Canadian Expeditionary Forces, France.
MATHEWSON, JAMES S., Private, Coast Artillery Training School, Coast Artillery, U. S. Army.
MILLER, A. S., Lieutenant-Colonel, Ordnance Department, U. S. Army.
MONTGOMERY, STAFFORD, Captain, Ordnance Department, U. S. Army.
NEDDERMANN, T. J., Coast Artillery, U. S. Army; stationed at Fort Tilden, N. Y.
ORR, BURTON S., Corporal, Co. 7, Engineer Officers' Training Camp, Engineers' Corps, U. S. Army.
PAINTER, W., Second Lieutenant, Air Service (Aeronautics), U. S. Army.
PRYOR, F. L., Lieutenant-Commander, U. S. Navy.
REDSTROM, E. R., Second Lieutenant, Ordnance Department, American Expeditionary Forces, France.
REED, JAMES, Commander, Construction Corps, U. S. Navy.
RUSTERHOLZ, R. W., Captain, Air Service, American Expeditionary Forces, France.
RYDER, E. R., Sergeant, Meteorological Section, Signal Corps, U. S. Army.
RYDER, M. P., Private, Air Service, Aeronautics, U. S. Army.
SAALFRANK, R. B., Lieutenant, Motor Transport Corps, U. S. Army.
SANBORN, FRANK E., Captain, Sanitary Corps, Medical Department, U. S. Army.
SEARS, H. R., Private, 24th Co., 6th Battalion, 160th Depot Brigade, Infantry, U. S. Army.
SERMULIN, FRED E., Military Specialist Co., American Expeditionary Forces, France.
SHERWOOD, H. P., Second Lieutenant, Chemical Warfare Service, U. S. Army.
SLEFFEL, C. C., Lieutenant, U. S. Naval Reserve Force.
SMITHE, F. B., Second Lieutenant, Heavy Coast Artillery, U. S. Army.
SPRUANCE, W. C., Lieutenant-Colonel, Ordnance Department, U. S. Army.
SWAN, JOHN J., Lieutenant-Colonel, Personnel Branch of the Operations Division, General Staff, U. S. Army.
SYMONDS, RALPH F., First Lieutenant, Tank Section, Ordnance Department, U. S. Army.
TAFEL, T., JR., 3rd Training Detachment, Radio Officers' Training School, Signal Corps, U. S. Army; stationed at Yale University.
TAYLOR, WALTER C., First Lieutenant, 11th Engineers (Railway), General Headquarters, American Expeditionary Forces, France.
TERRIBERRY, G. G., Candidate, Field Artillery Corps, Officers' Training School, 12th Training Battery, Camp Taylor, Ky.
VANDERBILT, CORNELIUS, Brigadier-General, U. S. Army.
VENNEMA, A. W., Second Lieutenant, Chemical Warfare Service, U. S. Army.
WALKER, FRANCIS J., JR., First Lieutenant, Fourth Anti-Aircraft Battalion, American Expeditionary Forces, France.
WALKER, K. G., Second Lieutenant, Air Service, U. S. Army.
WARNER, R. M., First Lieutenant, Ordnance Department, U. S. Army.
WESTWATER, ANDREW, Lieutenant, U. S. Naval Reserve Force.
WEISS, ERWIN A., Sergeant, Engineering Division, Ordnance Department, U. S. Army.
WEISS, LOUIS T., Sergeant, Motor Transport Corps, American Expeditionary Forces, France.
WENZLIK, RICHARD H., U. S. Naval Training Station, Great Lakes, Ill.
WILKE, ERWIN L., Ensign, U. S. Naval Reserve Force; assigned to Naval Experimental Station, New London, Conn.
WILLIAMS, H. J., First Lieutenant, Ordnance Department, U. S. Army.
WILLIAMS, PAUL, First Lieutenant, Inspection Division, Ordnance Department, U. S. Army.
WILLIAMS, SAMUEL C., First Lieutenant, Ordnance Department, American Expeditionary Forces, France.
WILSON, HENRY L., Lieutenant, Quartermaster Corps, American Expeditionary Forces, France.
WITHINGTON, SIDNEY, First Lieutenant, Co. 2, Section B, Engineer Officers' Training Camp, Camp Humphreys, Va.
WORTHINGTON, EDWARD H., First Lieutenant, Army Intelligence School, American Expeditionary Forces, France.
WRIGHT, A. MILES, Candidate, Engineer Officers' Training Camp, Camp Humphreys, Va.
WUERTH, E. A., Private, Field Artillery, U. S. Army; Replacement Depot, Camp Jackson, S. C.
YAGER, JOHN E., Private, Signal Corps, 4th Co., Section B, Students' Army Training Corps, University of Michigan.
YOUNG, C. D., Lieutenant-Colonel, Transportation Corps, U. S. Army.
ZACH, I. M., Candidate, Engineer Officers' Training School, Camp Humphreys, Va.

LIBRARY NOTES AND BOOK REVIEWS

AERO ENGINES, MAGNETOS AND CARBURETORS. By Harold Pollard. The Macmillan Co., New York, 1918. Cloth, 4 x 6 in., 84 pp., 15 illus., 15 pl. $1.

A brief manual, written in simple language and intended for beginners, which makes no pretense to be an exhaustive technical treatment of its subject.

AUTOMOTIVE MAGNETO IGNITION. Its Principle and Application, with Special Reference to Aviation Engines. By Mich. E. Toepel. First edition. Spon and Chamberlain, New York, 1918. Cloth, 4 x 8 in., 103 pp., illus., charts, diags. $2.

Presents the subject in the form of questions and answers covering the general principles of magneto ignition. References to specific types of apparatus have been avoided. Numerous illustrations and wiring diagrams are included.

CENTRAL STATION HEATING. By Byron T. Gifford. Second edition. Heating and Ventilating Magazine Company, New York, 1918. Cloth, 6 x 9 in., 278 pp., 34 illus., tables. $3.

Particular attention has been directed in this edition to the regulations adopted by the various state governments for the control of public utilities, especially to the methods of cost accounting necessitated by rate and valuation investigations. The discussion of high-pressure steam distribution has been expanded and the entire book has been revised.

COAL AND ITS SCIENTIFIC USES. By William A. Bone. (Monographs on Industrial Chemistry.) Longmans, Green and Co., New York, 1918. Cloth, 6 x 9 in., 491 pp., illus., pl., charts, diags., tables. $7.

The author, who was chairman of the British Association Fuel Economy Committee in 1915-17, has tried to give in essential outlines an account of the present state of science and practice in relation to coal and its various uses.

Beginning with an account of the general and scientific aspects of the coal question from a British point of view, there follows a review of the present state of science regarding the origin and chemistry of coal, including its distillation, oxidation and combustion. The latter part of the book considers the principal economic and industrial uses of coal as a fuel, and closes with an account of surface combustion.

The monograph is intended to provide a succinct account of the statistical, chemical and technical aspects of the subject as a whole, without unnecessary details, for use by the scientific public, and especially by that section interested in the chemical side of the subject.

CONVEYANCE AND DISTRIBUTION OF WATER FOR WATER SUPPLY. Aqueducts, Pipe-lines and Distributing Systems. A Practical Treatise for Water-Works Engineers and Superintendents. By Edward Wegmann. D. Van Nostrand Co., New York, 1918. Cloth, 6 x 9 in., 663 pp., 367 illus., 8 pl. $5.

By restricting himself to the conveyance and distribution of water, the author has been able, within the limits of a single volume, to discuss the subject in sufficient detail to be of practical value to engineers and superintendents of water works. Beginning with a chapter on the consumption of water, the flow of water in aqueducts and pipes is next discussed. Then follow chapters on the design and construction of pipes, aqueducts, service reservoirs, stand-pipes and tanks, fire protection and high-pressure systems. The remaining chapters take up maintenance and operation, the cleaning of aqueducts and mains, thawing frozen pipes, leakage, electrolysis, pipe tools and the detection and prevention of water waste.

DAVISON'S TEXTILE BLUE BOOK, UNITED STATES AND CANADA. Cotton, Woolen, Silk, Jute, Flax and Linen Manufacturers; Dyers, Bleachers and Print Works; Commission Merchants; Converters and Brokers; Yarn, Cotton, Waste, Linter Dealers; Mattress Manufacturers; Wool, Rag and Mill Remnant Dealers; Raw, Thrown and Spun Silk Dealers, etc. With a full classified Directory of Cotton and Woolen Mills and a Textile Supply Directory. Thirty-first annual edition, July 1918 to July 1919. Davison Publishing Co., New York (copyright 1918). Cloth, 7 x 9 in., 1471 pp., 7 maps. $5.

This directory covers the textile manufacturers, dyers, bleachers, printers, commission merchants, dealers, and makers of textile mill supplies in the United States and Canada. The various lists are carefully classified for quick reference. The capitalization, officers, equipment, products and railroad connections of each mill are given. Maps showing the location of the textile mills of the country are included.

ELECTRIC WELDING. A Comprehensive Treatise on the Practice of the Various Resistance and Arc-Welding Processes, Covering Descriptions of the Machines and Apparatus Used and the Applications, both in Manufacturing and Repair Work. By Douglas T. Hamilton and Erik Oberg. First edition. The Industrial Press, New York, 1918. 294 pp., 217 illus., 2 tables. $2.50.

A summary of present practice. The authors announce that they have had the assistance of the most prominent American firms engaged in this work, and that they have thus been able to present information on the latest improvements and discoveries.

ENGINEERING DIRECTORY. Buyers' Reference Section. 1918 edition. A Comprehensive Directory of Manufacturers of Mill, Steam, Mine, Plumbing, Heating and Lighting Supplies, Machinery and Tools. The Crawford Publishing Co., Chicago (copyright 1918). Cloth, 8 x 11 in., 566 pp.

This volume contains a list of American manufacturers, trade names and brands of industrial and engineering supplies and machinery, arranged under approximately four thousand subject headings, and a directory of manufacturers. An extensive cross index to the classification is provided.

THE J. E. ALDRED LECTURES OF ENGINEERING PRACTICE, 1917-18. The Johns Hopkins University, Department of Engineering. The Johns Hopkins Press, Baltimore, 1918. Paper, 6 x 9 in., 263 pp., illus., 2 folded pl., 1 map.

A presentation of the tangible and obvious features and principles of present engineering practice, intended to instruct the undergraduate students of the University in every-day working methods of design, construction, and operation.

MAP READING AND TOPOGRAPHICAL SKETCHING. By Edwin R. Stuart. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 5 x 8 in., 139 pp., 46 illus., 1 map. $1.

This textbook represents the results of the author's thirteen years of experience in the practice and teaching of topographic surveying and sketching at the United States Military Academy.

PRACTICAL SURVEYING AND FIELD WORK. Including the Mechanical Forms of Office Calculations with Examples Completely Worked Out. By Victor G. Salmon. J. B. Lippincott Co., Philadelphia, 1918. Cloth, 5 x 8 in., 204 pp., 87 illus., 3 folded diag.

The author has endeavored to supply to students a series of calculations which, in connection with well-known textbooks, will equip the young surveyor for the practice of the profession. The work consists mainly of solutions to questions set in examinations for qualification as surveyors in the South African colonies. It is not intended as a textbook, and includes only so much theory as is necessary to explain the examples.

THE RESULT OF MUNICIPAL ELECTRIC LIGHTING IN MASSACHUSETTS. By Edmond Earle Lincoln. (Hart, Schaffner & Marx Prize Essays, No. 27). Houghton, Mifflin Co., Boston and New York, 1918. Cloth, 5 x 8 in., 484 pp., 14 charts, 1 map, 58 tables. $3.

As a contribution to the discussion on the advantages and disadvantages of public ownership, the author has prepared this impartial, comparative study of results in one well-established business in a specific locality where adequate records covering

a period of years can be secured. The aim of the book is to suggest and exemplify those methods of approach and investigation which may most profitably be followed in future studies of the problems of municipal and state ownership. It is based on a careful, personal statistical study of the annual returns made by the plants to the Massachusetts Board of Gas and Electric Commissioners and a personal survey of the plants themselves.

Screw Propellers. An Estimation of Power for Propulsion of Ships. Also Airship Propellers. By Rear Admiral Charles W. Dyson, U. S. N. Second edition, rewritten. John Wiley & Sons, Inc., New York, 1918. Cloth, 325 pp., 62 illus., 32 pl., 18 tables, 2 vols. (text and atlas). $7.50.

The first edition of this work on propeller design suffered, the author states, from two serious faults; one being the vagueness of the method for determining the thrust-deduction factor and the other being the method of applying it in determining the characteristics of the propeller. These have both been eliminated to a great degree in this edition and other improvements have been introduced in the text. The author's ideas on cavitation are now fully presented. A chapter on airplane-propeller design has been added.

Steel Shipbuilder's Handbook. By C. W. Cook. Longmans, Green & Co., New York, 1918. Flexible cloth, 4½ x 7¼ in., 123 pp., 4 folding plates. $1.50 net.

The author, who is associate professor of naval architecture at the University of Southern California, has prepared this convenient pocket-size work for the use of men working in shipyards and for students in shipbuilding classes, the purpose being to acquaint them with the meanings of the terms used in steel ship construction. About 1600 names of parts, tools, operations, trades, abbreviations, etc., are defined, and drawing of some 300 parts are shown on folding plates.

Structural Service Book. Volume I. A revised Reprint from the 12 Issues for 1917 of the *Journal of the American Institute of Architects*, Structural Service Department. D. Knickerbacker Boyd, Editor. The Journal of the American Institute of Architects, Washington, 1918. Cloth, 9 x 12 in., 226 pp., including Industrial section. $3.50.

The first volume of an annual review of structural activities throughout the United States with particular references to the standards adopted or under consideration by the various societies, associations or other agencies whose work concerns itself in any way with the materials which enter into building construction, the methods and safety of their production, manufacture and erection.

The material is classified and indexed for ready reference. Under each heading are given lists of references to publications giving general information, describing recommended practice and adopted standards.

Seven Hundred French Terms for American Field Artillerymen. By Edward Bliss Reed, with a Foreword by Lieut. Col. Robert M. Danford. Second edition. Yale University Press, New Haven. Cloth, 4 x 5 in., 66 pp. $0.50.

A brief vest-pocket vocabulary of the French words most frequently used in field artillery.

Shop Management and Systems. A Treatise on the Organization of Machine-Building Plants and the Systematic Methods that Are Essential to Efficient Administration. By Franklin D. Jones and Edward K. Hammond. First edition. The Industrial Press, New York, 1918. Cloth, 6 x 9 in., 307 pp., 159 illus. $2.50.

The purpose of this volume is to give definite information on various systems that have been adopted, particularly in machine-building plants, to insure orderly and effective methods of procedure in the administration of manufacturing, designing and purchasing departments. Concrete examples, rather than theoretical ones, fill the greater part of the book, and show exact details of different systems and their application under various conditions.

Sir William Ramsay. Memorials of His Life and Work. By Sir William A. Tilden. London, 1918. Cloth, 6 x 9 in., 311 pp., 4 pl., 4 por. $4.

Sir William Tilden has written an interesting, readable account of Ramsay's career which does justice to his scientific work and gives at the same time a pleasant picture of the man himself. He has had the advantage of Lady Ramsay's coöperation, and has made use of the letters preserved by her and other members of the family.

Steel Shipbuilders' Handbook. An Encyclopedia of the Names of Parts, Tools, Operations, Trades, Abbreviations, etc., used in the Building of Steel Ships. By C. W. Cook. Longmans, Green and Co., New York, 1918. Flexible cloth, 5 x 7 in., 123 pp., 4 folded plates. $1.50.

This handbook is intended to help the men now obtaining employment in shipyards to understand the unfamiliar terminology and processes of steel ship building. It gives, in a compact volume of pocket size, an alphabetical list of definitions of some 1600 names, and plates illustrating about 300 parts of steel ships. The definitions have been collected from standard textbooks and a study of the methods now used in American shipyards.

Studies on Solution in Its Relation to Light Absorption, Conductivity, Viscosity, and Hydrolysis. A Report Upon a Number of Experimental Investigations Carried Out in the Laboratory of the Late Professor Harry C. Jones. Compiled by Paul B. Davis. Carnegie Institute, Washington, D. C., 1918. Paper, 7 x 10 in., 144 pp., 25 illus., 116 tables. $2.

The report represents the various lines of investigation pursued under Professor Jones's direction during 1915-16, all having some bearing upon the conceptions of solution in general and of solution in particular which have been developed by that laboratory.

The Submarine in War and Peace. Its Developments and Its Possibilities. By Simon Lake. J. B. Lippincott Co., Philadelphia, 1918. Cloth, 6 x 9 in., 302 pp., 18 illus, 53 pl., 1 portrait, 1 map, 1 folded diag. $3.

Mr. Lake's endeavor has been to provide an interesting popular account of the mechanical principles of the submarine, the history of its development, its actual operation, the difficulty of combating it and its industrial possibilities.

Vacuum Tubes in Wireless Communication. A Practical Textbook for Operators and Experimenters. By Elmer E. Bucher. Wireless Press, Inc., New York (copyright, 1918). Cloth, 6 x 9 in., 174 pp., 219 illus. $1.75.

The author explains over 100 different circuits for the practical use of vacuum tubes, which have been used from time to time in the laboratory and commercial practice, and gives a brief and simple explanation of the manner in which vacuum-tube circuits act.

Waterworks Handbook. Compiled by Alfred Douglas Flinn, Robert Spurr Weston and Clinton Lathrop Bogert. Second edition. McGraw-Hill Book Co., Inc., New York, 1918. Flexible cloth, 6 x 9 in., 824 pp., 411 illus., 313 tables. $6.

The new edition of this compilation of information for designers and operators of waterworks differs only in minor matters from the first one, published in 1916. All errors which have been found have been corrected, some small additions of new material have been made and a few portions have been rewritten to utilize recent information.

The Zinc Industry. By Ernest A. Smith. Longmans, Green and Co., New York, 1918. Cloth, 6 x 9 in., 223 pp., illus., 2 diag., 4 pl., 1 map., tables. $3.50.

The author of this volume of the series of Monographs on Industrial Chemistry has written a general survey of the development of the zinc industry and its present and possible future position in relation to the various metal industries of Great Britain. The rise and progress of the industry, the new materials and their sources, marketing of ores and metal, smelting, physical and chemical properties, industrial applications and alloys are considered, and a bibliography of the more important publications is appended.

Library Accessions

American Society for Testing Materials. A.S.T.M. Standards, 1918. *Philadelphia, 1918.* Purchase.

Archives des Sciences Physiques et Naturelles. Tables générales des Auteurs et des Matières. 1879-1910. *Genève, 1917.* Purchase.

Carbolic Acid and its Production from Benzol. By Geo. H. Stevens. *Newark, 1916.* Gift of author.

Chemistry of Photography. By Raphael Meldola. *London, 1891.* Gift of Samuel Wein.

Cleaning and Electro-plating of Metals. By H. H. Reama. *New York, 1917.* Gift of Samuel Wein.

Cutting Lubricants and Cooling Liquids and on Skin Diseases Produced by Lubricants. Memorandum. *London, 1918.* Gift of Great Britain. Department of Scientific and Industrial Research.

Education of Mine Employees. By H. H. Stock. (Illinois Miners' and Mechanics' Institutes. Bulletin No. 1.) *Urbana, 1917.* Gift of A. D. Flinn.

Efficiency in the Use of Oil Fuel. A handbook for boiler plant and locomotive engineers. *Washington, 1918.* Gift of Bureau of Mines.

English Catalogue of Books, 1917. *London, 1918.* Purchase.

Federal Valuation of the Railroads in the United States. Statement prepared by Thomas W. Hulme, vice-chairman, of the Developments in connection with Federal Valuation as of Sept. 20, 1918. Gift of Clemens Herschel.

List of Inspected Mechanical Appliances, July 1918. *Chicago, 1918.* Exchange.

Arthur D. Little Company, Industrial Research Laboratories. Descriptive booklet. *Cambridge, 1918.* Gift of company.

McGraw Electric Railway List, August 1918. *New York, 1918.* Purchase.

Memorial of Amos P. Brown. By R. A. F. Penrose, Jr. (Reprinted from the *Bulletin of the Geological Society of America*, v. 29, pp. 13-17, 1918.) Gift of author.

Oil and Petroleum Manual for 1918. By Walter R. Skinner. *London, 1918.* Purchase.

Organization of War Transportation Control. Railroad Committee, Chamber of Commerce of the United States. *Washington, D. C., 1918.* Gift of Railroad Committee.

Principles of Mechanics. Ed. 4. *London, 1794.* Gift of Charles Macdonald.

TRADE CATALOGUES

Coppus Engineering & Equipment Company. Worcester, Mass. Turbo Blower for undergrate draft and other industrial purposes. Descriptive booklet.

Fellows Gear Shaper Company. Springfield, Vermont. Internal Gear, design and operation. Descriptive catalogue, 1918.

Gem Stopper Company. Philadelphia, Pa. Bulletin No. 8. Universal acid carboy stoppers, asbestos gaskets and metal fasteners. 1918.

Hires Turner Glass Company. Philadelphia, Pa. Bulletin No. 2. Wire Glass and Why.

Jeffrey Mfg. Co. Columbus, Ohio. Bulletin no. 246. Jeffrey Pit car loader.

Jones & Lamson Machine Company. Springfield, Vt. The Fay automatic lathe; a machine for the automatic turning of work held on centers or on centered arbors. 1918.

Luitwieler Pumping Engine Co. Rochester, N. Y. Illustrations and descriptions of non-pulsating power pumps.

Sypho Chemical Sprinkler Corporation. New York, N. Y. The combination of a system and a service. 1916.
——— Service of Protection. 1916.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by January 15 in order to appear in the February issue.

CHANGES OF POSITION

James P. Calderwood, formerly associated with the engineering and inspection division of the Travelers Insurance Company, Hartford, Conn., has become professor of gas and steam engineering, The Kansas State Agricultural College, Manhattan, Kan.

Charles H. Stoddard has severed his connection with the Moore Shipbuilding Company, of Oakland, Cal., of which he was chief engineer, and has accepted the position of consulting marine engineer with the Heine Safety Boiler Company, Phoenixville, Pa.

August Ulmann, Jr., until recently associated with Walter Kidde and Company, Philadelphia, Pa., in the capacity of construction engineer, has assumed the duties of power engineer with the National Aniline and Chemical Company, Marcus Hook, Pa.

Fred E. Rogers, Jr., formerly with the J. G. White Company, New York, has accepted the position of sales engineer with the Fafnir Bearing Company.

A. E. Norrman, formerly professor at the Technical University, Helsingfors, Finland, has recently accepted a position as engineer with the F. W. Horne Company in Tokyo, Japan, importers of American machinery.

C. H. Bean has resigned as assistant superintendent of motive power of Armour and Company, and has accepted a position as chemical engineer on the advisory board of the Calco Chemical Company, Bound Brook, N. J.

Charles W. E. Clarke has become associated with Dwight P. Robinson and Company, Inc., constructing and consulting engineers, who have recently opened offices at 61 Broadway, New York. Mr. Clarke was formerly affiliated with the Stone and Webster Engineering Corporation, Boston, Mass.

C. T. Henderson has resigned as chief engineer of the Submarine Boat Corporation, Port Newark Terminal, Newark, N. J., and has become identified with the Hercules Engineering Corporation, New York, as its chief engineer, also acting as president of the Electrolytic Engineering Corporation at the same address.

O. C. Bornholt, formerly factory manager, Holley Brothers Company, Detroit, Mich., has become mechanical engineer of the Buick Motor Company, Flint, Mich.

John J. Eyre has resigned his position with the Worthington Pump and Machinery Corporation, to accept the position of factory engineer with the Sturtevant Aeroplane Company, Boston, Mass.

Byron T. Mottinger has severed his connection as general superintendent of power at the Fort Dodge, Des Moines and Southern Railroad, Boone, Ia., to become associated as chief engineer and master mechanic with the Quaker City Rubber Company, Wissinoming, Philadelphia, Pa.

ANNOUNCEMENTS

M. William Ehrlich, after ten months' service at the U. S. Government Explosives Plant, Nitro, W. Va., as engineer on progress for the Thompson-Starrett Company, has become associated with the George H. Gibson Company, New York, engineering and editorial specialists.

C. W. Koiner is engaged in war work at the United States Shipping Board, Emergency Fleet Corporation in the Power Section, Division of Shipyard Plants.

John R. Freeman, Past-President, Am.Soc. M.E., has resigned as president of the Providence Gas Company, effective January 1, in order that he may be free for another trip to China, where he will supervise surveys and plans for the modernizing of the Grand Canal.

H. B. Viele has received a commission as Ensign, U. S. N. R. F., to be assigned for engineering duties only.

Edwin L. King has been elected secretary-treasurer of the Pratt and Cady Company, Hartford, Conn. He succeeds to the treasurership of the late Bishop White and retains the position of secretary.

Lieut.-Colonel Thos. B. Whitted has recently been released from duty with the United States Army. Colonel Whitted, then a Captain in the E. O. R. C., was called to the colors in April 1917 and after a few weeks was ordered to duty with the American Expeditionary Forces, and for nearly a year was in immediate charge of all purchases for the Corps of Engineers in France. He was rewarded with a Majority for this work, and at his own request was sent to front line duty with troops, from which he was relieved in July 1918, promoted to Lieutenant-Colonel and ordered to the United States to bring over a new Regiment of Sappers.

APPOINTMENTS

Albert M. Brown has been appointed district manager of sales, Philadelphia, Pa., of the Chicago Pneumatic Company. Mr. Brown has been located in the New York offices of the company as assistant manager of the compressor sales division.

Gershom Smith, formerly comptroller of the Pennsylvania Steel Company, and more recently vice-president of the Tabulating Machine Company, after seven months in the office of the Quartermaster-General at Washington, has been appointed consulting accountant in the engineering firm of George W. Goethals and Company, Inc., New York.

H. de B. Parsons has been appointed civilian engineer, Aircraft Production, Approvals Department, U. S. A.

Harold C. White has been appointed factory manager of The Harris Manufacturing Company, of Stockton, Cal. During the last three years Mr. White has been actively engaged in the reorganization of the plants of the Holt Manufacturing Company, of Stockton, Cal., and at Peoria, Ill.

AUTHORS

Lieut.-Colonel E. C. Peck, Engineering Bureau, Ordnance Department, has contributed an article on Types of Reamers and Their Use to the December issue of *Machinery*.

E. A. Uehling is the author of an article entitled Combustion in Its Relation to Boilers, in the December 3 number of *Power*.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping any one desiring engineering services. The Society acts only as a clearing house in these matters.

POSITIONS AVAILABLE

Stamps should be inclosed for transmittal of applications to advertisers; non-members must accompany applications with a letter of reference or introduction from a member; such reference letter will be filed with the Society records.

PRODUCTION, PLANNING AND SCHEDULING ENGINEERS, to act as assistant shop superintendents in Hull Division. Salary to start $6.00 per day. Location, New York. A-0513.

SALES ENGINEER, young, with experience in power-plant equipment. Technical graduate preferred Excellent prospects. Location, Philadelphia, Pa. A-0524.

ASSISTANT TO DIRECTOR, Engineering Experiment Station. Some practical editorial experience required; initiative and ability to carry out work with minimum supervision. Salary dependng largely upon age, experience and training of man. A-0558.

SUPERINTENDENT, for barrel-manufacturing division. Absolutely essential to have had experience on barrels of light-gage steel, also on oxy-acetylene. Splendid opportunity for right man. Location, Massachusetts. A-0579.

U. S. NAVY STEAM ENGINEERING SCHOOL: U. S. Navy Department has perfected plans for the enrollment and training of considerable numbers of engineering officers. A school for this purpose, the U. S. Navy Steam Engineering School, has been established by the Department at Hoboken, N. J. Open to men between the ages of 21 and 40 who meet the physical requirements of the Navy, thorough ability and officer-like character and who have completed the mechanical or electrical engineering course at certain recognized technical schools, or who possess an education and experience judged to be an equivalent thereof. Enrollment men properly qualified may be made at any Naval Enrolling office, notation being made of the applicant's qualifications and desire to be detailed to this school. Men already in the Naval Service and properly qualified should apply for admission to the course to the Commanding Officer. Enroll at any naval enrolling office. For information write Assistant to District Enrolling Officer, 102, New Orleans, La. A-0660.

MECHANICAL ENGINEER, with good record, thoroughly experienced in design of high-grade steam engines and boilers, particularly of the marine type; able to handle draftsmen. Give age, experience in detail, salary desired. Location, Pennsylvania. A-0838.

CHIEF ENGINEER, familiar with design of structural and plate work, hoisting and conveying machinery of the heaviest type. Must have executive ability of the highest order. Give age, experience in detail and salary wanted. Location, Pennsylvania. A-0839.

MECHANICAL ENGINEER, to take charge of engineering office of chemical plant. State qualifications and salary desired. Location, New Jersey. A-0840.

MEN, young, to assist master mechanic of rolling mills. Would like men with technical education but not absolutely essential. Work necessitates knowledge of industrial plant equipment; preferably steel-mill equipment. Future prospects good. Give complete history of experience and salary expected. A-0842.

SALESMAN, to handle line of rotary, centrifugal and force pumps, selling to jobbing trade. State fully experience and qualifications, will be treated confidentially. Engagement first of the year. Location, Buffalo, N. Y. A-0847.

MAN, between ages of 30 and 40, with successful experience as an industrial executive; who anticipates the trend of industrial developments, including material markets, labor conditions, management methods, domestic sales opportunities in new fields, etc. One familiar with metal-stamping industry preferred. Good opportunity for right man. Reply by letter, giving age, education in detail, married or single, experience, present and expected salary. A-0848.

CHIEF ENGINEER, American, good education, practical experience, unimpeachable character and exceptional ability, with mature judgment and good personality. Must have executive as well as constructive capacity. Will be required to assume control of engineering department in manufacture of precision machine tools, keep in touch with the demands of customers and the output of competitors, so far as matters of design are concerned. Mere inventor cannot fill the requirements. Position will be made attractive to right man. If in a big position already, will not interfere with plans. Location, New England. A-0849.

DRAFTSMAN AND TRACER, on ship and yacht hull work. Two men for office of naval architects and marine engineers. Preferably men with previous experience along these lines. Location, New York. A-0850.

INSTRUCTOR in mechanical engineering for Southern University, to teach shop-work and drawing, possibly mechanism. Salary $1,600 per year. In reply state age, education, experience, photograph and copies of letters of recommendation. A-0851.

ORGANIZING ENGINEER, young, for high-grade time study and intensive management work. Bro d and expanding field for able man, large rubber factory. Location, Ohio. A-0852.

MECHANICAL DRAFTSMAN, by old established concern in small town. Living conditions excellent. Permanent position to right party. Give full information in first letter. A-0853.

INSTRUCTOR in mechanical engineering. Technical graduate with both teaching and practical experience. Give complete statement of qualifications, late photograph, height and weight. Salary $1,500 to $2,000. Location, District of Columbia. A-0854.

MECHANICAL ENGINEER, progressive; familiar with the engineering and operating of briquetting plants. A-0857.

DRAFTSMAN, first class on power-station design. Location, Providence, R. I. A-0858.

DISTRICT REPRESENTATIVE AND SALES ENGINEER, familiar and in touch with power-plant installations, furnace construction and general engineering products in Cleveland, Detroit and Cincinnati. Must be engineer of good standing, having sales ability and wide acquaintance in the engineering profession. Headquarters, New York. A-0859.

MAN, technically trained, to take charge of industrial furnace department for company manufacturing oil and gas-burning furnaces, used for tempering tools and steel, also for forging. A man big enough to take complete charge and direct the designing, development work, planning, estimating, and sales engineering of this department. Need technical man to handle propositions for specifications and estimates. Location Massachusetts. A-0860.

SUPERINTENDENT, for well-organized plant manufacturing high-grade printing machinery. Must be experienced executive and thoroughly versed in modern methods of interchangeable manufacturing. Give age, nationality, experience and salary expected. Location, near New York. A-0862.

MEN, young, educated in mechanical lines, particularly with a knowledge of internal-combustion engines, to develop into sales engineers. Location New York. A-0863.

WORKS ENGINEER, and maintenance of machinery operation of steam. Electric power-plant construction and maintenance of building and equipment. Permanent position with old-established concern. Location, Corning, New York. A-0864.

PRODUCTION AND PLANNING ENGINEER. Salary from $3,000 to $4,000, depending upon the ability of the applicant. A-0867.

SALES ENGINEER. Preferably one with technical education, but must have full knowledge of power-plant practice. Oldest and largest concern manufacturing high-grade power-plant equipment requires two additional men in the field. State last position held, giving full details and minimum salary to start. A-0868.

MECHANICAL DRAFTSMAN, with technical training or equivalent. Experienced in layout and detail of combined mechanical and structural work, able to handle machinery on cranes, conveyors, swing bridges or sluice gates, etc. Must be thoroughly capable, able to work without constant supervision, and to produce results quickly. A-0869.

ASSISTANT FOREMAN, for maintenance department. Young man just out of college or a mechanical engineering graduate with slight experience, large manufacturing company. Location, New England. A-0870.

DESIGNING ENGINEER, for large industrial plant, building excavating machinery. Prefer technical graduate with experience on similar class of work. Salary dependent on ability of man. Location middle-west. A-0872.

DRAFTSMAN AND DETAILERS, for industrial plant lay-out work, preferably men with experience in elevating and conveying machinery. State age, education, nationality, previous experience and salary desired. A-0873.

MECHANICAL DRAFTSMAN, with from one to three years' experience on designing of machine tools, jigs and fixtures. Technical graduate preferred. Salary depending upon ability and experience. Excellent opportunity for right man. Location, Connecticut. A-0874.

DESIGNING MECHANICAL ENGINEER, thoroughly experienced in coal and ore-handling equipments; shipbuilding and wharf cranes; conveying machinery, etc. High-grade technical man wanted to take charge of design. State education, nationality, salary desired. Information confidential. Location, Canada. A-0876.

ENGINEER, with some experience in the thermodynamic design and calculation of steam turbines. Prefer young, capable man, to work into responsible position. A-0877.

MAN, of wide experience in same line as No. 0877. A-0878.

ENGINEER of good executive ability and some experience on steam turbines, to handle a variety of work under direction of the chief engineer. A-0879.

STEAM TURBINE DRAFTSMAN, capable of doing development and improvement work. Give full information as to training and experience. Location New England. A-0880.

DESIGNING ENGINEER, experienced on high-pressure steam engines of the poppet valve and kindred types. Location, St. Louis. A-0882.

MECHANICAL ENGINEER, for field work. Must have technical training, preferably college graduate with at least 10 years' experience in construction and operation of power-plant machinery, including steam engines, steam and hydraulic turbines and internal-combustion engines. Preference given to practical man

with sales experience and wide knowledge of industrial plant equipment gained through operation or inspection work. Give age, training and experience. Salary $2,000 to $3,000. Apply by letter. A-0883.

TECHNICAL WRITER, preferably former assistant editor on engineering publication, or instructor in college of mechanical engineering. Should have ability to make technical subjects clear to non-technical readers. Knowledge of a wide variety of machinery, its construction and operation, through extensive reading and practical experience, together with ability for editorial work, are essential qualifications. Reply in detail, giving training, experience and age, with salary desired. Apply by letter. A-0884.

TECHNICAL MANAGER, as assistant to branch sales manager. Should be mechanical engineer with about five years' experience in design, construction and operation of various classes of prime movers. Executive and sales ability in handling work of a number of engineers in the field essential. Sound theoretical training and broad knowledge of mechanical equipment required, in order that man selected may conduct technical educational campaign throughout sales and engineering organization. State age and give training and experience. Salary $2,000 to $3,000. Apply by letter. A-0885.

MECHANICAL ENGINEER, young. College education and some ability and training in research work. Salary would be from $150 to $200 per month. Location New Jersey. A-0886.

CHIEF ENGINEER, with unusual ability to organize an engineering force for development of design, planning and efficiency experimental work, etc., for large manufacturing company is marketing an article enjoying an international market. Only high-grade successful men will be considered. Splendid opportunity for right man. Apply by letter. A-0887.

PLANT MANAGER, with broad experience in operating lines. Must have unusual ability to handle men. Will be expected to take over an organization of not less than 4000 men in manufacturing a high-grade commercial article in New England territory. Experience required will be along mechanical lines. Must be employed at present time and receiving not less than $8000 per year. Splendid opportunity for right man from standpoint of advancement and emolument. Only very successful operators will be considered. Apply by letter. A-0888.

MEN AVAILABLE

Only members of the Society are listed in the published notices of this section. Copy for notices should be on hand by the 12th of the month, and the form of notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

MECHANICAL ENGINEER, experienced in power-plant work, heating, sanitary drainage, and fire protection systems in design, layout, purchase of material, and supervision of installation; desires position abroad, preferably in reconstruction work in France or Belgium. American born, age 25. Minimum salary $3,600. A-1.

PRODUCTION ENGINEER, M.E. Columbia 1915; 3½ years' practical experience in shop as inspector, drafting room and office work; production man, conversant with bookkeeping and accounting, desires position, offering good prospects, preferably in or around New York City. Minimum salary $2,500. A-2.

MECHANICAL ENGINEER, age 25, technical graduate; 3 years' experience in design and manufacture of riveted plate metal. Also plant layout and machinery installations. Now Lieutenant in Research Division, Chemical Warfare Service. A-3.

FUEL ENGINEER, graduate M.E., 10 years' experience in combustion work and economical utilization of coal for industrial purposes. Withes to be connected with consulting engineering firm in fuel work. At present time in Government service. A-4.

TECHNICAL GRADUATE, 7 years' experience, power plant and general plant engineering, layout, installation and maintenance, turbines, condensors, boilers, stokers, conveyors, switchboard, gas producers, heating and ventilating systems. Married. Salary $200 per month. Philadelphia preferred. At present employed. A-5.

CHIEF ENGINEER OR CHIEF DRAFTSMAN, member, graduate M.E., resourceful, inventive designer. Shop experience. Age 44 years. New York or Newark preferred. Willing to invest in small or medium concern. A-6.

SUPERINTENDENT OR ASSISTANT, 18 years' experience in mechanical and executive positions, from tool-maker to superintendent inclusive, in high speed production of interchangeable parts. American, 26 years old, married. Will consider any location. A-7.

MECHANICAL ENGINEER, French, 48; extensive engineering, designing and operative experience in United States, Central and South America; steam and gas engine, marine and stationary, mining machinery, machine tools; 10 years' locomotive construction and supervision. Would like connection with firm having interests in Europe or South America. Now employed by U. S. Ordnance. End of war necessitates change. Highest references. A-8.

SPECIALIST IN MARINE, OIL AND GAS engine design with 17 years' practical experience in development and research work. Extensive training in the fine points of both the technical and business side of combustion engineering, competent to handle men and to perfect engine designs along proven lines that will eliminate waste of time and money. Excellent man for assisting war-plants that contemplate shifting over output into new lines. Salary $4,800 per year. A-9.

ENGINEERING EXECUTIVE, now in military service in charge large group on important war research, will be available for industrial service February 1. University training, supplemented by 10 years' successful engineering experience, the last seven as industrial engineer for ten million dollar corporation in charge of staff handling problems of production and business organization. Age 32, married, excellent health. Prefer location in New York or New England in community offering good home and school advantages. Initial salary $5,000, with good opportunity for advancement, and preferably a chance to later acquire an interest in the business if connection is mutually satisfactory. A-10.

TECHNICAL M.E. graduate, 1915, with three years' practical shop experience, desires position, preferably in sales work, or assistant to manager. At present employed by the Navy Department. A-11.

PRODUCTION ENGINEER, graduate M.E. Cornell University, age 28. Now engaged in war work. Captain, Ordnance Department. Available January 1. Desires position as superintendent or assistant superintendent, or similar executive position. Salary $3,000 to $3,600. A-12.

MEMBER, 15 years' experience with consulting engineer in designing and erecting special machinery, laying out industrial plants, blast furnaces, steel mills, buildings, etc. Also experienced in purchasing and exporting mechanical equipment. Now employed. Location, Philadelphia, or the vicinity. A-13.

CONVEYING ENGINEER, two years field engineer and construction foreman for Philadelphia concern; 8 years construction, estimating and sales engineer, now production superintendent for ordnance department U. S. A. and immediately available. A-14.

EXECUTIVE, ELECTRICAL AND MECHANICAL ENGINEER, age 43, married, desires an executive position; capable as an ordnance manager, or efficiency engineer; 15 years' experience in research and efficiency work in executive position; available at once. Least salary, $6,500. A-15.

WORKS MANAGER OR SUPERINTENDENT, age 41, married, graduate engineer, experience from apprentice to works manager in large organizations and modern methods of manufacture of munitions, heavy machinery, engines, single-purpose machines and tools, accustomed to handling all classes of labor. Desires permanent position with large concern where prospects are good. Personal reason for wishing change. A-16.

MECHANICAL ENGINEER. Age 44. Born in Russia, speaks, reads and writes English, Russian and Polish, also some German; technically trained, 13 years' shop practice experience as mechanic; 28 years' total continuous American experience in general mechanical engineering; railway specialist in design and construction of heavy machinery and in design of passenger equipment and structures. Desires position in connection with reconstruction of Russia. Now employed. A-17.

MECHANICAL ENGINEER, equipment to handle responsible position; 25 years' actual experience covering design and construction of shops, power plants, layouts and transmissions, thoroughly conversant with blower systems for heating, ventilating and designing jigs, fixtures, special tools and gages; some experience with automatics. Age 50 years; married. New York preferred. A-18.

GRADUATE M.E. 1917, mechanical and production engineering experience. Location, New York or Long Island preferred. A-19.

FOREIGN TRADE: Technical man, speaking five languages, varied experience in organizing and operating industries, making investigations of trade requirements and possibilities in Europe and the Latin Americas; establishing agencies and directing their activities, permanent connections with a large organization, contemplating the establishment of foreign relations. A-20.

MECHANICAL ENGINEER, master mechanic thoroughly experienced in tools, process, design, etc., on internal-combustion engines; efficiency work, planning and scheduling; plant layout, design and maintenance; 30 years old, American. New York City or vicinity preferred. A-21.

MECHANICAL ENGINEER; power-plant work a specialty. Age 24. Desires location with consulting engineers in Chicago or middle west or with manufacturing concern. Also in the members' exchange; desires to invest money and enter business with a consulting engineer or small concern in the middle west. prefer power-plant work. A-22.

EXECUTIVE ENGINEER, university graduate capable of taking charge of engineering, designing or experimental department; 7 years' experience in design and construction of internal-combustion engines. Practical shop experience and thoroughly acquainted with modern manufacturing methods and systems. A-23.

GENERAL OR WORKS MANAGER. Graduate Worcester Poly. Institute. Age 45, married. Broad selling and manufacturing experience as sales executive and works manager. Special ability in reorganization and the handling of men. Competent to fill very responsible executive position. Temporarily employed in War Dept. Service now available. Location, New York City or vicinity preferred. A-24.

MANAGER of ship yard or large machine works. Many years' experience as general sales manager, managing executive, consulting mechanical and electrical engineer. Employed at present as industrial manager of large and important plant U. S. Navy. Skilled in marine electric propulsion. Only high-grade connection will be considered. Salary $6,000 to $7,500. A-25.

MECHANICAL ENGINEER, 8 years' technical graduate, employed as master mechanic of large industrial plant in charge of power generation and distribution, maintenance and repair of all mechanical and electrical equipment, and repair shops; 2 years drafting and designing. Broad experience with internal-combustion machinery, modern steam turbo-generating plant and mining and milling machinery. Can handle men successfully and produce results to bring costs down to a

possible minimum. Available January 1, 1919. 34 years old, married. A-26.

ENGINEER-EXECUTIVE. Twelve years' experience in the design, construction and operation of industrial plants and public utilities; specialized in the problems of management. Desires position as manager or assistant. Location, New York City or vicinity. At present employed as assistant manager and chief engineer of large corporation. A-27.

AMERICAN, with wide experience in the manufacture of heavy machinery, such as steam shovels, dredgers, pile drivers, cranes and mining machinery, desires position with old established concern. 39 years of age. Salary not less than $3,000. A-28.

MECHANICAL ENGINEER in Government service desires position as assistant to superintendent of progressive manufacturing establishment. Graduate of high-grade technical institution with 3½ years' practical experience. Location in vicinity of Philadelphia preferred. A-29.

MEMBER, 20 years' experience marine engines, turbines, boilers, power plants and auxiliaries, ice machines, etc. Naval architecture, structural and electrical engineering. Now employed by large shipbuilding corporation in machinery fabrication department but desires permanent connection with concern who can offer advancement in keeping with ability. A-30.

HEATING, VENTILATING AND POWER PLANT ENGINEER. Technical graduate desires position as designing engineer or superintendent. At present employed in cantonment construction as mechanical superintendent for contractor. Previous experience designing engineer and chief draftsman in charge of design of mechanical equipment of buildings. Thoroughly conversant with all modern types of heating, ventilating, plumbing and power plant construction. Salary $2,500 to $3,000. Prefer location in East or Middle West. A-31.

M.E. AND C.E. GRADUATE ENGINEER, experienced in sugar engineering, automobiles, tractors, small arms, research engineering, design and production, formerly professor of machine design, now Captain, Ordnance Dept., U. S. A., supervising inspector. Wishes position as chief, production or operating engineer or as professor of mechanical engineering in well-established technical school, or position in France or England. A-32.

TECHNICAL EXECUTIVE AND OPERATING MANAGER with broad standard gage steam-railway operating experience, desires position abroad. American parentage. Technical graduate of two universities, receiving degrees in mechanical engineering and railway engineering. Age 35, unmarried. Experience as practical railway shop expert, designer of locomotives and cars, operating superintendent in the organization and management of steam railway lines, valuation and appraisal of railway property. Now in U. S. military railway service. Good personality, resourceful and dependable. Excellent references. Salary $8,000. A-33.

INDUSTRIAL ENGINEER, 20 years' experience in designing, purchasing, construction, production, manufacturing and maintenance work. Previously chief engineer of large paper manufacturing corporation, operating twenty-five mills. Recently mechanical engineer for contracting company, buying, laying out and installing mechanical equipment for ammonium-nitrate, shell-loading and acid-manufacturing plant. Married. Located in New England but willing to go anywhere for reasonable salary. A-34.

TECHIICAL GRADUATE. Age 28, Captain in supply branch, U. S. A., during war emergency; desires position as assistant to production or works manager of progressive manufacturing concern. Broad training in production with modern methods of centralized graphic control. Electrical and automobile manufacturing experience. Salary about $3,000. A-35.

MECHANICAL ENGINEER, now employed making technical investigations and analyses of reports for the Ordnance Department, U. S. A., seeks connection with scientific management firm in New York City. A-36.

MANAGER OR ASSISTANT MANAGER, technical graduate, U. S. Army officer. Age 29. General manufacturing experience. Active and aggressive executive. Successful record in handling men. Practical knowledge shop methods, plant maintenance, construction, engineering, employment and safety, incentive wage emethods and general office work. Married. Prefer connection as assistant manager of large concern or factory manager small concern. Salary $5,000. A-37.

COMBUSTION ENGINEER. Expert in analysis, management, operation and maintenance of large boiler operations. Experienced in modern equipment and operations up to 60,000 hp.; age 35, technically trained, progressive, excellent references. Would like to locate with firm or corporation having large power house or chain of power houses. Salary $5,000 per year. A-38.

MECHANICAL ENGINEER, experienced executive, technical graduate, 20 years' experience, including special research work, design, construction, maintenance, general supervision and operation of industrial plants. A-39.

ELECTRICAL AND MECHANICAL ENGINEER, age 32 years, married; graduatae of Cornell University and University of Utah; 10 years' experience in generation, transmission, application and sale of energy, management of power concerns; desires position requiring executive capability. Foreign service entirely acceptable. A-40.

CORNELL GRADUATE with 15 years' experience desires connection with tractor or threshing machinery concern as works manager. Experienced in efficiency methods and up-to-date organization; salary dependent on condition and location. A-41.

GRADUATE M.E., 2 years' experience drafting and surveying, 2 years in army as officer. Speaks French, German slightly. Desires position preferably with concern expecting to do engineering work in France. A-42.

EXECUTIVE, mechanical or power superintendent or mechanical engineer. Age 35, married, with wide general mechanical and electrical experience in large industrial plants, chemical plants, paper mills and power plants, with record showing marked improvement in operation and operating costs. Present salary $4,000 per year. Will consider salary of $5,000 with chance of advancement. A-43.

SUPERINTENDENT. Excellent mechanical and manufacturing experience. Age 45. A-44.

ORDNANCE OFFICER, First Lieutenant in Engineering Division. Technical graduate of prominent engineering college. Age 25, married, experienced in mechanical and production engineering in varied line of manufacturing. Qualified to sell mechanical equipment. Willing to go anywhere and especially in reconstruction and development work abroad.

SALES OR PRODUCTION ENGINEER. Army officer expecting discharge at an early date desires connection with progressive concern. Age 28, married, technical graduate. Civilian experience covers 6½ years' designing, manufacturing and selling pumping and filter-plant machinery. Can furnish references from prominent engineers and manufacturers. Minimum salary $3,600. A-46.

FACTORY SUPERINTENDENT, M.E. graduate with several years' experience in manufacturing, filling and casing for export, plain and lithographed cans; thoroughly familiar with dies, special can machinery, soldering machines and conveying systems. Salary to start $3,500. A-47.

M.E. GRADUATE, 33 years old, extensive experience in manufacturing plants, desires position with good live company where advancemens is assured provided work is satisfactory. Holds Captain's commission in Ordnance Department. Reliable and with understanding of proper coördination of departments. A-48.

MECHANICAL ENGINEER, M.I.T. 1917, shop and general engineering experience, desires opening as assistant to mechanical or efficiency engineer. A-49.

DESIGNING ENGINEER, experienced on tools and special machinery for ordnance and aeroplane-engine work, also valves, fittings, boiler accessories and pipage systems. Production experience with 3 years thorough shop training. Technically trained. Age 27. Will go anywhere. Salary considered $2,400. A-50.

MECHANICAL ENGINEER. Technical graduate 1915. Experienced as designer of automobiles starting, lighting and ignition equipment, Army Ordnance. At present with the Government as designer and experimental engineer having had charge of design, manufacture and testing of experimental war material. Desires position preferably production in an executive capacity. Salary $225 per month. A-51.

EXECUTIVE ENGINEER, 18 years' experience in design, construction and operation of textile plants, technical graduate, married, open to engagement with permanent construction company or high-class manufacturing concern. Salary $7,000 or will consider a proposition taking interest in small business. Middle west or New England preferred. A-52.

MECHANICAL ENGINEER, at present constructing large sugar mill in tropics; at liberty December; desires connection with firm doing work in tropics and needing man capable of bringing to a finish big construction. Sugar mill or power plants. Can design and estimate as well as superintend this class of construction. Salary $6,000. Married, age 32. A-53.

SALES EXECUTIVE, with executive, engineering, sales and business ability, can handle general sales department, including advertising, of medium-size manufacturing concern or district office for large concern. 32 years old, married and U. S. native born. Considerable experience in Canadian market. A-54.

ENGINEER EXPERT, both in training and experience; specialized in machinery construction as applied to building operations and ship construction, and production experience. Can furnish the best of credentials. At present employed with Navy Dept. Bureau of Construction and Repair, available any time during 1919; prepared to accept foreign service. A-55.

FACTORY MANAGER OR SUPERINTENDENT, mechanical engineer with 18 years' practical experience in manufacture of light and heavy machinery; twelve years an executive organizer, expert in manufacture of interchangeable machinery, able to originate, design and build automatic or semi-automatic machinery for automobile or printing press. Past experience covers layout of entire plant, purchase and installation of equipment. Would consider representation abroad; thoroughly familiar with European countries and conversant with French language. 38 years old, married. Salary $6,000. A-56.

CONSTRUCTION ENGINEER, 12 years' experience design and construction of factories, large buildings and shipyards, including the mechanical, electrical and civil engineering features. Responsible charge of construction of over $12,000,000 worth of work for private interests including preparation, letting and adjustment of contracts; experience in maintenance and operation of completed structures and power plants. Cornell graduate, M.E., age 34, leaving Government position held during war and desires to make permanent connection with factory or construction company. Earned $7,000 to $8,000 per year before war. Will consider less on agreeable work with prospects of advancement. Particularly interested in labor problems. Location near New York City preferred. A-57.

POWER SPECIALIST, 10 years' unusual experience in design, construction and operation of steam, hydroelectric and internal-combustion engine power houses; high-tension distribution, electric substation work and the application of industrial power to machine-tool equipment. Recently in charge of 50 men on the design and construction, and 1000 men

on all mechanical and electrical work at a 12-way, 8800 ton tractor employed by the Emergency Fleet Corporation. Executive engineer of good personality, age 30, married, M.E. degree; open for employment January 1, 1919, with contractor, consulting engineer or manufacturer. A-58.

EXECUTIVE, DESIGNER, Harvard A.B., 1909, Cornell, M.E., 1911. Age 32, married; 7 years' practical experience in shop, drafting room, industrial plant and isolated field work in connection with internal-combustion and steam engines; gas producers and boiler plants. Experienced in organization work and recently state boiler-plant conservation work for U. S. Fuel Administration. Desires management of small business with partnership or stock interest. Minimum salary $3000. A-59.

MECHANICAL ENGINEER, graduate, 5 years' experience in development and manufacture of machine tools, instruments and steel-plate work, as designer, estimator, plant engineer. Desires executive position. At present with the Government in executive engineering capacity. New York or Boston district preferred. A-60.

MECHANICAL ENGINEER. Technical graduate. 17 years' experience in the design, construction, testing and operation of steam power plants, 11½ years' as designer, builder and superintendent of power plants and stationary steam equipment with two of the largest eastern railroad systems. At present employed as engineer with public utility operating and engineering corporation. Desires to return to steam railroad work or enter permanent employ of strong manufacturing company. A-61.

SUPERINTENDENT OR PRODUCTION ENGINEER, age 44. Mechanical engineering graduate, 16 years' experience in industrial engineering lines, 8 years with present employer in supervision of rate setting, production planning. Costs, pay roll, shop accounting, etc. for shop employing 600 to 900 people. Position in which an interest in business could be obtained preferred. Location Chicago. A-62.

AUTOMOBILE AND AIRPLANT ENGINE EXPERT just released from Army, wants position with school or manufacturing concern. Graduate M.E. Cornell University, 1909. Thorough knowledge of carburetion, ignition, starting and lighting systems, storage batteries, etc. Also experience in experimental work of various kinds. Salary not less than $3000. A-63.

SUPERINTENDENT OR CHIEF ENGINEER of power plant, or power engineer for manufacturing plant; 14 years' experience since graduation. American, 36 years. Design, construction operation and maintenance of steam plants and substations a specialty. Salary $3000. Eastern States. A-64.

POWER ENGINEER, 7 years' experience in construction, operation, reconstruction and design of power plants, buildings, and equipment. Covering boilers, stokers, turbines, oil engines and refrigeration equipment. Supervising engineer for consulting engineering firm of New York before entering U. S. Navy as Ensign. Desires to cover the purchase of equipment, direction of field work, and organization of plants on an efficient and economical basis. Salary on entering service $3000. Willing to go anywhere. Available about February 1. A-65.

SALES ENGINEER. Member, with New York office will accept manufacturers' account or representative for special or plant equipment. Broad selling experience combined with practical manufacturing shop knowledge. Resourceful. Bank reference. A-66.

ASSISTANT ENGINEER OR SUPERINTENDENT; technical graduate, age 28, married. 5 years' general shop, maintenance and construction work; one year experimenting with powdered coal. Desires permanent position with large manufacturing corporation. Active and energetic. Now employed. Location preferably East or Middle West. A-67.

DRAFTSMAN AND SALESMAN specializing in iron and bronze; 1½ years chief estimator leading car works; 3½ years chief estimator engineer, design, manufacture, sale and installation conveying apparatus of all types. At present commissioned officer U. S. Army, Ordnance Dept. design and production work. Available about January 15. A-68.

INDUSTRIAL PLANT ENGINEER. Age 40, married. Technical education; 16 years' wide experience in industrial plant engineering and management consulting, designing, construction, organizing, maintenance, shipyards, paper and pulp mills, power plants. Desires position as engineering manager or works engineer. Executive ability with broad knowledge of plant management and organization. A-69.

MANAGER with broad manufacturing experience and successful record desires big, difficult executive position. A-70.

MECHANICAL ENGINEER desires staff connection with firm of industrial engineers, to undertake for clients power-plant investigations, schedule process steam demands, and effect fuel economies. A-71.

PRODUCTION ENGINEER, graduate mechanical engineer, age 27. Experience in supervising including routing, scheduling and developing progress charts and reports; following up machine-shop production and operations from time of casting ingot to shipment. One year's experience as chief inspector of small arms. Philadelphia or vicinity preferred. A-72.

SUPERINTENDENT, mechanical or production engineer; energetic, progressive American, married; technical education with broad experience in shop, drawing room and production on small interchangeable parts. Ability to produce results. At present employed. Available at early date. A-73.

GRADUATE UNITED STATES NAVAL ACADEMY, honorable resignation from the U. S. Navy; age 36, married; 6 years' civilian executive engineering experience, followed by enrollment in U. S. Naval Reserve Force. At present stationed in China. Would like to get in touch with firms who are either now operating or who contemplate starting in any part of the Far East. A-75.

MECHANICAL ENGINEER, officer in the Engineers Corps, U. S. Army, age 33, desires position affording opportunity for exercise of executive ability. Technical training and experience in construction and operation industrial plants. Thoroughly familiar with power plants and power-plant equipment; experienced in machine design; broad general business training. Minimum salary $300 month. Available about January 1. A-75.

COMBINATION ENGINEER desires position with company whose fuel consumption is sufficient to require services of first-class man. Technical training, wide experience in practical problems of design and operation of furnaces for special work, machine designer. Available on release from military service on or about January 1. A-76.

MECHANICAL ENGINEER, age 25, married; M. I. T. graduate with 2½ years' practical experience in industrial and power-plant engineering. Desires to become connected with concern that can offer future in return for hard work, energy, and initiative. Willing to make moderate start if future is assured. Now employed. Location preferably in the East. A-77.

MECHANICAL ENGINEER, technical graduate, age 24. Release from active duty in Naval Reserve in December. Experienced foundry engineer, metallurgist, and metallographist. Will consider position as estimator for foundry or steel-works equipment, or sales engineer and special representative for manufacturer. Varied experience in the engineering field and natural curiosity and ingenuity gives qualifications for position as assistant to work manager or superintendent. A-78.

PRODUCTION ENGINEER, desires position where opportunity is given to show initiative and accomplish constructive work. Experience in plant management and reorganization; association with leading industrial engineers and executive experience in several large plants as superintendent and production engineer. Technical graduate, age 28 years. A-79.

ADVISORY ENGINEER, 25 years experience in design of blast furnaces, steel plants, hydraulic machinery, sugar mills, machine shops, foundries, boiler shops, power plants, and heavy machinery as well as supervising the erection and construction, including laying out foundations and placing and erecting buildings and machinery. A-80.

NAVAL AVIATION ENGINEER OFFICER; M.E., Stevens, 1909; age 31; served apprenticeship in machine shop of gasoline-engine manufacturer. Has held position of draftsman, efficiency and plant engineer; employment supervisor, factory superintendent and mechanical engineer with well-known manufacturing concerns. A-81.

COMBUSTION ENGINEER, 10 years' experience with coal, gas and oil firing, wishes to make change. A-82.

MECHANICAL ENGINEER with 7 years' broad mechanical manufacturing experience, desires position with possibilities as superintendent or manager, upon release from active duty as commissioned officer in Ordnance Department. Can furnish best references. A-83.

MECHANICAL ENGINEER with 15 years' experience in design of heavy machinery, plant and building construction, thoroughly familiar with shop and field methods; desires permanent connection with definite opportunities for advancement. Technically trained, with experience as machinist. Age 36, married. A-84.

ELECTRICAL, MECHANICAL DRAFTSMAN, graduate Rose Polytechnic Institute, 1915. In charge drafting, last three years on work including shell machinery, oil-well equipment, hydraulic pumps, safety work. Would like opportunity leading to works management, efficiency or sales engineer. A-85.

DIESEL ENGINEER SPECIALIST, with 3 years' experience erecting, testing, design, and computation of Diesel engines. M.E. Mass. Inst. Tech. Now holds responsible technical position. Desires change from advanced experimental work on Diesels to position involving standard practice. A-86.

ENGINEER, just discharged with rank of lieutenant, Engineer Corps; 3½ years' prior experience in power-plant and distribution systems, design and construction in all their electrical, mechanical, and structural details. Age 26, married; available at once. Salary $2400. A-87.

PRODUCTION OR MECHANICAL ENGINEER would like to become permanently established with live or growing concern; inventive and executive ability, age 31, married. Excellent references. At liberty the first of the year. A-88.

MECHANICAL AND CIVIL ENGINEER, several years in charge of engineering department with large manufacturing company, desires to make change. Experience has been in estimating and designing with close connection with production. Also in charge of building design construction and plant extension. Preference, assistant to manager of large and growing plant. Would consider car specialty concern of recognized standing. A-89.

GRADUATE MECHANICAL ENGINEER, just released from 15 months' military service, captain artillery, now interested in steam power-plant proposition, or manufacturing, operating or consulting opportunities. A-90.

MECHANICAL OR PLANT ENGINEER, 3 years at engineering college, 5 years apprentice engineering works, 12 years' practical experience. Last 5 years in charge of engineering department of large manufacturing establishment. Married; 35 years of age. A-91.

MECHANICAL ENGINEER, technical graduate, desires position as manager where executive ability is necessary, with an extensive knowl-

edge of modern scientific and production management methods. Held positions of superintendent and factory manager and with consulting industrial engineers. Only a high-grade proposition will be considered. A-92.

PRODUCTION MANAGER. Mechanical engineering graduate, familiar with practical machine-shop and foundry work and relating office methods. Desires position with progressive manufacturing firm requiring an energetic and tactful executive. At present in Government service, available the first of the year. Excellent references. 30 years old, married. Salary $3000. A-93.

MECHANICAL AND SALES ENGINEER, age 36, married, 19 years' experience. Available on January 1, 1919, familiar with European business practice. Desires agency for South America or Europe, flour-mill and grain-elevator machinery; Diesel-oil engine, marine or stationary, gas producer for bituminous coal gas or steam engine. Salary and commission preferred. Can lay out plants and superintend erection or installation of same. A-94.

YOUNG MECHANICAL AND CHEMICAL ENGINEER, desires to change position. Experienced in construction, operation, and maintenance of industrial works. References. Location wherever desirable. A-95.

MECHANICAL ENGINEER, desires connection in sales engineering or executive capacity. American, in excellent health. Graduate University of Michigan in engineering and naval architecture. Unusual combination of successful selling, technical and business experience in both mechanical and marine fields. Former member Chicago firm mechanical and electrical engineers; also business manager large real estate and contracting firm. At present employed on Government shipbuilding work, but seeks permanent connection. Will go anywhere, and available on reasonably short notice. A-96.

MECHANICAL ENGINEER, University technical education, desires connection of executive nature with manufacturing concern, preferably in early stages of development. Several years' experience directing work in office, plant and field along lines of plant construction, design and installation of mechanical equipment, plant operation and sales. At present holding commission in Government service. Will consider position in foreign field. A-97.

MECHANICAL ENGINEER, technical graduate, desires position in executive department of engineering or manufacturing concern; 12 years' experience covering design, construction and manufacturing. American, age 35; married; energetic and trustworthy. Employed at present but available on short notice. A-98.

MECHANICAL ENGINEER, desires position as technical executive. American and British training and experience, in hoisting machinery and structural engineering. Student of modern organization and production methods. At present chief draftsman of large concern. Desires position in South America or Europe with up-to-date plant or in developing freight-handling facilities at ocean terminals. A-99.

MECHANICAL ENGINEER, technical graduate, 14 years' general engineering experience, including machine design, executive staff work, supervision of heavy construction, machinery installation and manufacturing, desires position requiring executive ability as resident engineer or manager. Only a high-grade proposition will be considered. A-100.

STEAM TURBINE DESIGNER, age 43, expert designer of steam engines and turbines and highly trained mechanical and electrical engineer; now employed by the Navy Department wishes to return to commercial work in an executive position. A-101.

MAJOR ENGINEER, R.C., about to return from active service as major of engineers abroad, desires connection with firm of consulting engineers or employment as manager or superintendent. Familiar with power and refrigerative plants, factory, layout and management, machine-tool design, and manufacture of duplicate machinery. A-102.

MECHANICAL ENGINEER, GENERAL SUPERINTENDENT, 30 years old, technical and practical experience. Machine-shop practice as tool-room superintendent; designer of special machinery, chief draftsman, special fixtures, tools, etc.; experienced in systematizing cost accounting, equipment developing experimenting. At present production superintendent. Originator of devices for manufacturing; has initiative, resourcefulness; seeks position of responsibility and permanency after January 15, 1919. T-103.

GENERAL OR WORKS MANAGER. Authority on modern employment and personnel problems. Graduate mechanical engineer and B.A. in economics; 20 years' experience including cost accounting, production management, purchasing and superintendence. Now holding professorship as head of department in large engineering college and consulting practice. Author of well-known books on industrial organization and management. Major of Ordnance since July 1917, having had charge of important equipment, production, and inspection work in ammunition and artillery. A-104.

MECHANICAL ENGINEER, technical degree, age 31, not married; 8 years' experience on general structural design, inspection work, construction of large mining plants, also buying and selling of machinery. Four years spent in South America, good knowledge of business conditions in that country. Desires to join firm where technical knowledge of foreign business would be of service. A-105.

MAINTENANCE AND CONSTRUCTION ENGINEER familiar with superintendence of building construction, installing automatic machinery, heat-treating furnace, fuse-oil storage equipment. Available on short notice. A-106.

ENGINEER, experienced in design, construction and operation of power plants, accustomed to take full charge of both office and field work; experience also covers design of special machinery and industrial layouts, special investigation in power problems, etc., desires location in vicinity of New York City. A-107.

GRADUATE MECHANICAL ENGINEER, with 2 years' experience on electrical and mechanical equipment. Discharged Army officer. Position desired with an industrial establishment as assistant to works manager or with industrial engineer. A-108.

EXECUTIVE ENGINEER, office and field executive in general engineering and contracting company. 20 years' broad experience covering the purchase, installation and maintenance of mechanical and electrical equipment for power, contracting and industrial concerns. Sales manager of electrical apparatus. Now in Government position. Available at once. Seeks responsible permanent connection. Technical graduate. Married. Salary $5,000. A-109.

MECHANICAL, CONSTRUCTION, PRODUCTION WORKS and plant-maintenance engineer, 32 years old, single, technical college education; several years varied engineering experience, in this country and abroad such as steel construction, power plants, foundry, machine and forge shops, preparing plans and specifications, estimates, etc., speak several foreign languages, considered good shop and office organizer and executive. Formerly captain U. S. A., recently discharged. Can present best reference. A-110.

PLANT ENGINEER, technical executive or assistant executive of any kind, requiring position of promise and responsibility as technical graduate; eight years' experience in executive capacity, covering manufacturing, plant testing, consulting engineer and teaching in machine design and power plants; at present 1st Lt. in U. S. Army, Ord. Dept., on design and manufacture of field carriages. 29 years of age, married. Location preferably New York or vicinity; salary $2,600-$3,600. A-111.

TECHNICAL GRADUATE age 26, 2 years' practical shop and 2 years' drafting experience. At present as leading draftsman in charge of work. References furnished as to ability, character, etc. Location, preferably Eastern States. A-112.

MECHANICAL ENGINEER. Graduate of Coöperative engineering course, University of Cincinnati, 1913, Junior Member, age 28, married. Now lieutenant in United States Army and will be available for civilian position about January 10, 1919. Four years' experience in consulting office, including two years as executive. Experience covers all details of mechanical, electrical and sanitary equipment for industrial buildings and design, construction and operation of steam power plants. Consulting practice chiefly in connection with paper mill work. Desires position in similar capacity with industrial engineer or architect, or other executive capacity in line with qualifications. Preferably in Middle West. A-113.

FACTORY EXECUTIVE who for some time has devoted his services to the U. S. Government on special work, would like to correspond with well-established concern. Experience consists of 21 years' in principal capacity with several well-known concerns in this country and Europe, in the manufacture and development of high-grade intricate mechanical devices, requiring extreme accuracy, interchangeability of parts, together with a very efficient organization, highest type of men, tools and equipment. A-114.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER JANUARY 21

Below is a list of candidates who have filed applications since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. The total number of applications received and listed below is 163.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by January 21, and provided satisfactory replies have been received from the required number of references, they will be balloted upon by the Council.

NEW APPLICATIONS
FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

California

DARRAH, William A., Plant Manager, Noble Electric Steel Co., Heroult

HEYLMAN, Frederic C., Chief of the Mechanical Department, Shell Company of California, Martinez

JESSURUN, David, Superintendent, The Anaheim Sugar Co., Anaheim

JONES, Edward S., Assistant Engineer, Gas Department, Pacific Gas & Electric Company, Sacramento

KOEBIG, A. H., Consulting Engineer, Los Angeles

MARTIN, Jesse C. Jr., Mechanical Engineer, J. C. Martin Company, San Francisco

Connecticut

ADT, HOWARD E., Treasurer & General Manager, The Geometric Tool Company, New Haven

BRANCHERRY, JOSEPH M., Production Engineer, Colts Patent Arms Company, Hartford

GAINES, WILBUR H., Superintendent, Factory "H," International Silver Co., Meriden

HAMMOND, GUY L., President & Treasurer, Block Rock Mfg. Company, Bridgeport

LAWRENCE, WILLIAM E., Head of Model Department & Designing Engineer, Marlin Rockwell Corporation, New Haven

RUST, CHARLES E., Supervisor of Apprentice Training School at the Bullard Engineering Works, Inc., Bridgeport

Delaware

BRUCE, ROBERT G., Mechanical Engineer, E. I. du Pont de Nemours & Co., Wilmington

District of Columbia

BALL, C. WINTHROP, Chief Draftsman, Engineering Division, Ordnance Department Aircraft Armament Section, Washington

STOVER, HARVEY D., Lieutenant Ordnance Engineer, Engineering Division, Aircraft Armament Section, Washington

STUART, KENNETH E., Member, Engineering Committee National Research Council, Washington

Illinois

EKLIND, CARL E., Chief Draftsman, Car Construction Department, Atchison, Topeka & Santa Fe Railway Company, Chicago

HELT, HARRY C., Assistant to Superintendent Engineering and Planning, Small Arms Division, Rock Island Arsenal, Rock Island

JAMES, SYDNEY V., Mechanical Engineer, Underwriters' Laboratories, Chicago

MORRISON, MONTFORD, Consulting Engineer, Victor Electric Corporation, Chicago

ROGERS, FRANKLIN G., Sales Engineer, Under-Feed Stoker Co. of America, Chicago

Indiana

CREAGER, EDWIN F., Works Manager, Remy Electric Division, Anderson

TEST, ELLIS W., Chief Mechanical Engineer, Haskell & Barker Car Company, Inc., Michigan City

Kentucky

WARE, ARTHUR L., Mechanical and Mining Engineer, Hazard

Maryland

EISERT, HERMANN, Mechanical Engineer, C. L. Reeder, Baltimore

HIGGINS, MAX S., General Manager, New York Central Iron Works Co., Inc., Hagerstown

Massachusetts

COYNE, JAMES F., Garage Manager, Seekonk

HAWLEY, THOMAS, President, Hawley School of Engineering, Boston

VAN LAW, CARLOS W., Consulting Engineer, Boston

Michigan

FENKELL, GEORGE H., Superintendent & General Manager, Board of Water Commissions, Detroit

HUNT, HORACE S., Administrative Engineer for Michigan, United States Fuel Administration, Detroit

Missouri

MARTINDALE, GERALD S., Construction Engineer, Curtis & Co. Mfg. Co., St. Louis

New Jersey

ANDERSON, RICHARD T., Branch Manager, Crocker-Wheeler Company, Newark

BRADY, THOMAS, Superintendent, Elevator Supplies Company, Inc., Hoboken

FORIS, JULIUS, Tool & Machine Designer, The Singer Sewing Machine Manufacturing Company, Elizabeth

KORTGARD, FREDERICK H., Foreman Engineer, Jersey City Power Station, U. S. Railroad Administration, Hudson & Manhattan R. R., Jersey City

McCLYMONT, JAMES, 2nd Vice-President, Hall Printing Press Company, Dunellen

New York

BARNSLEY, HERBERT J., Chief Draftsman, Jenkins Brothers, New York.

BORGSTEDT, HENNING N., Sales Engineer, De La Vergne Machine Company, New York

BYER, HENRY E., Chief Engineer, Condenser Department, Ingersoll Rand Company, New York

CHAMBLISS, HARDEE, Major, Ordnance Department, U. S. A., Laurel Hill Detachment, Laurel Hill, Long Island

CHURCHILL, WILLIAM L., Consulting Engineer (Industrial Efficiency), New York

COURTLAND, WILLIAM A., Vice-President & Engineer, H. W. Cotton, Inc., New York

ERDMAN, ALBERT W., Lieutenant-Colonel, Ordnance Department, U. S. A., Schenectady

ESTEP, FRANK L., Chief Engineer, Perin-Marshall Company, New York

HICKS, OSCAR P., Sales Engineer, Mathews Gravity Carrier Company, New York

LIPKE, LEOPOLD H., General Manager, Gotham Machine & Tool Company, Inc., Brooklyn

LISETZKY, PETER A., Chief Engineer, Gun Carriage Plant, New York Air Brake Company, Watertown

MARTIN, KINGSLEY L., President, The Engineer Company, New York

PASCALE, PASQUALE, Designing Engineer, Galvanizing Corporation of America, Brooklyn

RANKIN, WILLIAM J. A., Cableway & Logging Engineer, Lidgerwood Manufacturing Company, New York

RAYMOND, FRANK S., Draftsman, Watervliet Arsenal, Watervliet

RICHARDS, HORATIO R. H., First Assistant Production Engineer, Standard Shipbuilding Corporation, Shooters Island

ROBB, EDWARD H., Chief Draftsman & Assistant to Engineer, Long Island Railroad, Richmond Hill, Long Island

ROSSIRE, HENRY L., Production Manager, U. S. Ordnance Department, New York District, New York

STEVENS, JOHN E., Mechanical Engineer, General Briquetting Company, New York

STRUNK, WALTER C., Assistant Engineer, Interborough Rapid Transit Company, New York

SUTHERLAND, KENNETH W., Chief Assistant Inspection Officer, Department of Gages & Standards, British War Mission, New York

Ohio

BAKER, WALTER C., Consulting Engineer, The Standard Parts Company, Cleveland

CUNNINGHAM, GEORGE F., Designing Draftsman, Ohio Blower Company, Cleveland

DIBBLEE, WALTER A., District Manager, Inspection Division, Ordnance Department, U. S. A., Cincinnati

FIELD, J. A., Planning Engineer, The B. F. Goodrich Company, Akron

MARSHALL, EDWARD M., Combustion Engineer, Union Gas & Electric Company, Cincinnati

Pennsylvania

BATTEY, WILLIAM A., Vice-President, Pennsylvania Crusher Company, Philadelphia

FORKER, JOHN N., Chief Draftsman, The Koppers Company, Pittsburgh

GRAHAM, ALVIN K., General Manager, Erie Bolt & Nut Company, Erie

HARTMAN, WILLIAM H., Chief Engineer, Pennsylvania Crusher Company, Philadelphia

KENNEDY, MATTHEW G., Assistant to Electrical Engineer, The United Gas Improvement Company, Philadelphia

LATIMER, JOHN, Superintendent of Meters, Bureau of Waters, Philadelphia

RITTMAN, WALTER F., Consulting Engineer, Pittsburgh

SUCZEK, ROBERT, Consulting Engineer, C. H. Wheeler Manufacturing Company, Philadelphia

Tennessee

HENSON, WALTER A., Vice-President, Osage Cotton Oil Company, Chattanooga

Texas

GILLESPIE, SOLOMON E., Assistant Engineer, The Murray Company, Dallas

Vermont

WINESTOCK, OTTO C., Inventive Industrial Research, Perkinsville

Washington

GODFREY, FOSKETT H., Superintending Engineers Constructing Quartermaster, Camp Lewis

THOMPSON, WALDO E. Mill Builder, Tacoma

WENK, MORRIS, Engineering Draftsman, G. M. Standifer Construction Corporation, Vancouver

Canada

CARTER, WILLIAM, Manager, Ingersoll Rand Company, Montreal

JONES, THOMAS M. Chief Engineer & Manager, The Bawden Pump Company, Ltd., Toronto

McKEE, GEORGE M., General Manager, The Donnacona Paper Company, Ltd., Donnacona, Quebec

Hayti

HOLLY, ROBERT A., Assistant Engineer, Stewart's Engineering Corporation, Port-Au-Prince

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

Connecticut

CAMPBELL, JAMES A., Assistant Scheduling Supervisor, Winchester Repeating Arms Company, New Haven

MORRISEY, RICHARD E., Component Engineer, Colts Patent Fire Arms Company, Meriden

District of Columbia

LEILICH, FRANK T., Captain of Engineers, U. S. A., Washington

Connecticut

SHRINER, EDWARD C., JR., 2nd Lieutenant, Ordnance Department, U. S. A., Assistant Supervisor on Fuses, Adapters and Bosters, Bridgeport

New Jersey

GERBER, LIPMAN S., 1st Lieutenant, Ordnance Department, 511th Casual Company, Camp Merritt

SOBEN, ADOLPH F., Designer, Splitdorf Electric Company, Newark

New York

HALLSTED, SEYMOUR J., Chief Engineer, The Griscom-Russell Company, New York

Pennsylvania

BUCKLEY, JAMES E., Turbine Designer, Bethlehem Shipbuilding Corporation, Bethlehem

DONEGAN, JOHN J., Foreman, Forge Department, Frankford Arsenal, Philadelphia

WILLIAMS, JOHN F., Construction Engineer, Atlantic Refining Company, Philadelphia

Rhode Island

SPRAGUE, FRANK D., Lieutenant, U. S. N. R. F., Exp. Officer, Torpedo Station, Newport

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Connecticut

BALSOR, FREDERICK N., Assistant Resident Inspector of Engineering Material, U. S. Navy, care Ashcroft Manufacturing Company, Bridgeport

COOK, HARMON T., Works Manager, The Torrington Co., Torrington

District of Columbia

LANG, HERBERT H., Supervising Inspector, Ordnance Department, U. S. Army, Washington

LAMBERT, STANLEY M., Assistant Branch Head, War Department, Estimates & Requirements Division, Washington

Illinois

FISKE, ROGERS A., First Assistant to Officer in Charge of Production, Rock Island Arsenal, Rock Island

RICE, PERRY W., Manager, Chicago Branch, Pratt & Whitney Company, Chicago

Massachusetts

NICKERSON, HAROLD L., Superintendent of Production & Employment Manager, Walden-Worcester, Inc., Worcester

Nebraska

LUEBS, AUGUST A., Instructor Mechanical Engineering, University of Nebraska, Lincoln

New York

KEEFE, Daniel C., Mechanical Engineer, Ingersoll-Rand Company, New York
SIMPSON, Robert E., Jr., Check Inspector, Gas Defense Plant, U. S. A., Long Island

Ohio

PATCHELL, Frederick J., Assistant Chief, Materials Engineering Department, Bureau Aircraft Production, Dayton

Pennsylvania

HILL, David B., Mechanical Draftsman, Ordnance Department, Frankford Arsenal, Frankford
KARN, Fred S., Sales Engineer, Dravo-Doyle Company, Pittsburgh

Virginia

LEFEBVRE, Gordon, Maintenance Engineer, Du Pont Company, Hopewell

West Virginia

RINKE, George R., Chief Engineer, West Virginia Traction & Electric Company, Morgantown

Canada

HASTIE, Christopher, Surveyor, Lloyd's Register of Shipping, Vancouver, B. C.
PARKIN, John H., Mechanical Engineer, British Acetones Toronto, Ltd., Toronto, Ontario

France

STEINS, Carleton K., 1st Lieutenant, Engineers, U. S. A., Co. "O," 35th Regiment, American Expeditionary Forces.

FOR CONSIDERATION AS JUNIOR

California

BERCAW, Corliss A., Chief Quartermaster, Aviation, U. S. N. R. F., Whittier
CHRISTIAN, Joseph D., Mechanical Engineer, P. H. Reardon, San Francisco

Connecticut

DURKEE, Chauncey H., 1st Lieutenant, Ordnance Department, U. S. A., Colt's Patent Fire Arms Manufacturing Company, Hartford
WHITAKER, John A., Assistant Chief Draftsman, Colt's Patent Fire Arms Manufacturing Company, Meriden

District of Columbia

McCUTCHEN, Brunson S., Captain, Ordnance, U. S. A., Washington
SORENSON, James C., Designer, Ordnance Office, U. S. Army, Washington

Illinois

HABERSTROH, Herbert N., Selling Engineer, Celite Products Company, Chicago

Louisiana

FREELAND, Emile C., Assistant Research Chemist, Louisiana Sugar Experiment Station, New Orleans

Maryland

BROWN, Ernest G., 2nd Lieutenant, Ordnance Department, U. S. A., Aberdeen Proving Grounds, Aberdeen
WELLS, Burling D., 1st Lieutenant, Chemical Warfare Service, Edgewood Arsenal, Edgewood

Massachusetts

ALDRIN, Edwin E., 1st Lieutenant, Instructor in Aeronautics, Massachusetts Institute of Technology, Cambridge

Michigan

HIGGINBOTTOM, Herbert, Jr., Tool and Gauge Designer, Packard Motor Car Company, Detroit

Minnesota

GREENBERG, Morris, Instructor Exp. Engineering Department, University of Minnesota, St. Paul

Missouri

SHANKS, Everett C., Assistant Superintendent Machine Shops, Curtis & Co. Mfg. Co., St. Louis

New Jersey

BEARDSLEY, Harry I., Supervising Mechanical Designer, Crocker-Wheeler Company, Ampere
DeLORME, Alfred C., Engineer in Charge of Specification, Splitdorf Electric Company, Newark
DERR, Carl W., Ensign, U. S. N. R. F., Jersey City
KOLB, Robert P., Chief Machinist's Mate, U. S. N., Steam Engineering School, Stevens Institute, Hoboken
MILLER, Frank W., Jr., 2nd Lieutenant, Ordnance Department, Commanding Officer 502nd Casual Company, Camp Merritt
PRANGE, Charles H., Draftsman, Federal Shipbuilding Company, Kearny

New York

ANDREW, Harold O., Captain, Ordnance Department, U. S. A., General Chemical Company, Laurel Hill, Long Island
FULFORD, Lester E., Captain, Chemical Warfare Service, U. S. A., New York
MARX, George, Jr., Ensign, U. S. N. R. F., New York
ROHMANN, Charles E., Sub-Inspector of Ordnance, Bureau of Ordnance, U. S. Navy Department, New Jersey Inspection District, Brooklyn
STEVENS, Raymond S., Manager of Production Service Department, Gas Defense Plant, Long Island City, Long Island
TAVENER, Charles H., Aeronautical Engineer & Mathematical Designer, Curtiss Engineering Corporation, Garden City, L. I.

Ohio

McCULLOUGH, James T., Aeronautical Mechanical Engineer, Bureau Aircraft Production, Dayton

Pennsylvania

CHADWICK, Joseph J., Mechanical Draftsman, Traylor Engineering & Manufacturing Company, Allentown
PARSONS, Seely S., 1st Lieutenant, Ordnance Department, Philadelphia

Rhode Island

FIELD, Ernest G., Providence
SPARKS, Earl C., Superintendent, Gorham Manufacturing Company, Phillipsdale

Virginia

GRIEBEL, Frederick W., Machinist, Newport News Shipbuilding & Dry Dock Company, Newport News

West Virginia

BLOUNT, Robert E., Assistant to W. C. Thatcher, Supervising Engineer, Area "K," Nitro

Brazil

JUNIOR, Francisco A., Industrial Railway Engineer, Tinidicio F. Amaro, St. Paulo

France

BARRON, David H., 2nd Lieutenant, U. S. A., Co. "I," 34th Engineers, American Expeditionary Forces.

West Indies

ROBERTS, Samuel B., Assistant Engineer, Bartram Brothers, Inc., Santo Domingo, Dominion Republic

CHANGE OF GRADING

PROMOTION FROM ASSOCIATE-MEMBER

Connecticut

BUXBAUM, William, Superintendent Tool Department, Winchester Repeating Arms Company, New Haven

Illinois

ROLLINS, Lewis M., General Superintendent, Armour Mechanical Company, Chicago

Massachusetts

SHAW, Benjamin C., Assistant Superintendent, Boston Duck Company, Bondsville

New York

STRATTON, David V., Consulting Engineer, New York

Pennsylvania

HAMILTON, Walter C., 1st Lieutenant, Ordnance Department, U. S. R., Frankford Arsenal, Philadelphia

PROMOTION FROM JUNIOR

Connecticut

ANDERSON, John W., Engineer, Electric Boat Company, Groton

District of Columbia

HUNT, James L., 1st Lieutenant, Engineering Division, Ordnance Department, U. S. A., Washington

Illinois

LANGSTROTH, Clifford B., Captain, Ordnance Department, Rock Island Arsenal, Rock Island

Michigan

BREEDLOVE, Lincoln B., 1st Lieutenant, Mobile Repair Unit, 14th Division, Camp Custer

Minnesota

BOYD, Ford E., Mechanical Engineer, Oliver Iron Mining Company, Duluth

New Jersey

DARROW, Herbert V., Assistant Mechanical & Electrical Engineer, T. A. Gillespie Loading Company, South Amboy

New York

BLUM, Joseph K., Secretary & Treasurer, K-B Pulverizer Company, Inc., New York
DAHLSTRAND, Josef Y., Chief Engineer, Kerr Turbine Company, Wellsville
HAVILAND, John R., Sales Engineer, Furman-Fisher Corporation, New York
TRUMP, Charles C., Vice-President & Secretary, Humphrey Gas Pump Company, Syracuse

Ohio

ROCKWELL, Willard F., Vice-President in charge of manufacturing, The Torbensen Axle Company, Cleveland

Canada

HEINEMANN, Adelbert L., Engineer of Tests, Ordnance Department, U. S. A., Canadian Allis-Chalmers, Ltd., Toronto

SUMMARY

New Applications	146
Applications for change of grading:	
Promotion from Associate-Member	5
Promotion from Junior	12
Total	163

SUMMARY SHOWING AVERAGE AGE AND POSITIONS OF APPLICANTS ON BALLOT, DECEMBER 14, 1918

Average age of applicants:	
Members	41
Associates	39
Associate-Members	34
Juniors	26
Chief Engineers	2
Commercial Engineer	1
Consulting Engineers	2
Designers	4
Draftsman	1
Chief Draftsman	1
Assistant Chief Draftsman	1
Efficiency Engineer	1
Electrical Engineer	1
Executives (Pres., Vice Pres., Secy., Mgrs.)	8
Hydraulic Engineer	1
Instructor	1
Maintenance Engineer	1

THE ENGINEERING INDEX

Published Monthly by The American Society of Mechanical Engineers

The Engineering Index was Founded in 1884 by the Association of Engineering Societies; Published from 1895 to 1918, inclusive, by The Engineering Magazine Company; and Acquired January 1919 by The American Society of Mechanical Engineers

The following pages form a descriptive Index to articles on engineering and related subjects in current periodicals. In its preparation the Society's engineering staff regularly examines all of the technical journals and society publications received by the Engineering Societies Library, which form one of the greatest and most complete collections of scientific periodicals in the world, comprising upward of 1100 distinct publications in some ten languages. Cross-references are freely introduced in the Index, and in all cases where the titles of articles are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC COPIES OF ARTICLES LISTED

The Society is prepared to supply photostatic copies (white printing on brown background) of any of the articles listed. Copies of the periodicals themselves, or clippings of articles, cannot be supplied.

Price of each print (up to 11 x 14 in. in size), 25 cents plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Those holding coupon books for clippings formerly issued by The Engineering Magazine Company may use the coupons in payment for photostatic prints. In ordering, state plainly

(1) Page number of Index on which item appears
(2) Title of article
(3) Name of periodical.

Orders should be sent to

Harrison W. Craver, *Director*,
Engineering Societies Library,
29 West 39th Street, New York City.

DIVISIONS OF THE ENGINEERING INDEX

Mechanical Engineering

AIR MACHINERY

Air Conditioning

Air Conditioning, Charles L. Hubbard. Domestic Eng., vol. 85, nos. 3 and 4, Oct. 19 and 26, 1918, pp. 82-84, 2 figs. and 118-120, 5 figs. Possibilities of this branch of heating and ventilating engineering and how it may save coal and raise efficiency of employees in industrial plant.

Pneumatic Tools in Winter

Effects of the Use of Pneumatic Tools on the Nervous System, Francis M. Barnes. Safety Eng., vol. 36, no. 4, Oct. 1918, pp. 239-240. Recommends warming chisel in cold weather, enlarging or covering shank to prevent cramp in hand muscles, and condemns practice of blocking exhaust outlet, thereby forcing current of cold air over fingers. From Proc. Seventh Annual Safety Congress.

CORROSION

A Case of Corrosion Caused by Electrolytic Action in a Westinghouse-Leblanc Air Pump (Un cas de corrosion à allure électrolytique dans une pompe à air Westinghouse-Leblanc), L. Conge. Revue Générale de l'Electricité, vol. 4, no. 15, Oct. 12, 1918, pp. 539-540, 2 figs. States that no pipe or machine element intended to operate exposed to direct action of any kind of water should be composed of metals capable of forming a voltaic couple.

FOUNDRIES

Brass Foundry

A Brass Foundry With Automatic Ventilation, Charles Vickers. Foundry, vol. 46, no. 316, Dec. 1918, pp. 568-574, 11 figs. Description of foundry with its ventilation arrangements.

Coreroom

Modern Coreroom for Malleable Foundry, Donald S. Barrows. Iron Age, vol. 102, no. 21, Nov. 21, 1918, pp. 1254-1255, 5 figs. Designed and constructed for 50,000-ton foundry, provides for economical handling of raw materials and finished cores. Abstract of paper before Am. Foundrymen's Assn., Oct. 1918. Also in Foundry, vol. 46, no. 316, Dec. 1918, pp. 577-578, 5 figs.

Die Casting

Die-Casting of Aluminum, H. Rix and H. Whitaker. Sci. Am. Supp., vol. 86, no. 2237, Nov. 16, 1918, pp 314-315. Advantages; heat treatment; material for dies; cost of process. Paper before Inst. of Metals.

Furnaces

Continuous Tunnel Furnace in Malleable Industry, Philip d'H. Dressler. Foundry, vol. 46, no. 316, Dec. 1918, pp. 566-567, 5 figs. Discussion of paper by H. E. Diller on Experiments in Annealing Malleable Iron, at annual meeting of Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

Electric Furnace in the Steel Foundry, W. E. Moore. Iron Age, vol. 102, no. 20, Nov. 14, 1918, pp. 1206-1207. Comparison of electric and converter costs; relation to power station; future of electric steel foundries. From paper before Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

Oil-Burning Cupola Operations Analyzed, John Howe Hall. Foundry, vol. 46, no. 316, Dec. 1918, p. 558. Results attained in melting iron for 3-ton converter plant point to saving in fuel and labor with more steady output. From paper before Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

Ladles

Suggest Standard Sleeves and Nozzles. Brick & Clay Rec., vol. 53, no. 11, Nov. 19, 1918, pp. 882-883, 21 figs. Standard dimensions for round-face and straight-face nozzle brick for foundry ladles proposed by Am. Face Brick Assn., also dimensions of sleeves for foundry ladles proposed by a committee of

Western (West.)

steel men and founders in joint assembly with a committee of manufacturers of sleeve and nozzle brick.

Malleable Iron

Malleable Iron Castings, P. A. Paulson. Iron Age, vol. 102, no. 21, Nov. 21, 1918, p. 1266. Advantages over steel castings for agricultural purposes. From paper presented at Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

The Integrity of the Malleable Casting, Enrique Touceda. Iron Age, vol. 102, no. 20, Nov. 14, 1918, pp. 1204-1205. Possibility of obtaining thoroughly sound castings; use of chills detrimental; effect of war on industry. From paper before Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

Molding

How Marine Cylinders Are Molded and Cast, F. H. Bell. Can. Machy., vol. 20, no. 22, Nov. 28, 1918, pp. 611-614, 7 figs. Description of method used in a Toronto plant.

Pit Molding an Intricate Condenser Casting. Foundry, vol. 46, no. 316, Dec. 1918, pp. 552-557, 10 figs. Structural difficulties, experienced more generally in light work, attended production of this 34,900-lb. casting.

Patterns

The Engineer in Relation to the Foundry, E. S. Carman. Iron Age, vol. 102, no. 20, Nov. 14, 1918, pp. 1200-1202, 13 figs. Machine designs not adapted to advanced foundry practice; comparison of correct and incorrect patterns for floor molding. From paper before Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

Pouring

A Modern Pouring System. Iron Age, vol. 102, no. 20, Nov. 14, 1918, p. 1203, 3 figs. New type of pouring device and hand crane.

Sand

Improving Foundry Sand Mixtures, Henry B. Hanley. Iron Age, vol. 102, no. 19, Nov. 7, 1918, pp. 1146-1148, 3 figs. Use of sand-mixing machine; time required for mixing; effect of sea coal and fireclay. From paper before Am. Fdrys. Assoc., Milwaukee, October 1918. Also in Foundry, vol. 46, no. 316, Dec. 1918, pp. 559-562, 5 figs.

Semi-Steel

Methods of Manufacturing Semi-Steel for Projectiles (Sui vari metodi di fabbricazione della ghisa per proiettili), Giulio Sirovich. Ingegneria Italiana, vol. 2, no. 4, Sept. 26, 1918, pp. 178-180.

Urgent Shell Need Found Foundries Ready. Foundry, vol. 46, no. 316, Dec. 1918, pp. 581-587, 15 figs. Manufacturing operations and practices developed in American foundries would have furnished tonnage of semi-steel shell beyond all prospective requirements.

Supervision

A Foundry Supervision System, Paul R. Ramp. Iron Age, vol. 102, no. 23, Dec. 5, 1918, pp. 1383-1385, 2 figs. Routine set of reports designed to provide quick and accurate gage of current costs and operations. From p per before Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

See also ELECTRICAL ENGINEERING, Power Applications (Furnaces).

FUELS AND FIRING

Ash

Clinker and Ash in Fuel. Times Eng. Supp., no. 527, Sept. 1918, p. 186. Methods employed for curtailing labor entailed in removing large and hard masses of clinker.

The Fusibility of Coal Ash and the Determination of the Softening Temperature, Arno C. Fieldner, Albert E. Hall and Alexander L. Field. Department of Interior, Bureau of Mines, Bul. 129, 1918, 146 pp., 38 figs. Review of literature on subject; effect of various oxidizing, reducing, and neutral atmospheres such as are found in various parts of fuel bed on softening temperature of ash when molded in form of Seger cones; development of method for determining fusibility whereby ash is caused to soften and form slags in which iron exists in approximately same state of oxidation as when in fuel-bed clinkers.

Boiler Firing

Combustion in Its Relation to Boilers, E. A. Uehling. Power, vol. 48, no. 23, Dec. 3, 1918, pp. 804-806. Describes requirements for complete combustion and discusses combustion efficiency and absorption efficiency.

Generation of Heat and Its Absorption by Boiler, Henry Misostow. Nat. Engr., vol. 22, no. 10, Oct. 1918, pp. 518-522, 4 figs., and (discussion) pp. 522-525. Conditions which will realize an efficient commercial combustion and suggestions to utilize heat indications in securing good performance in boiler room. Paper before Nat. Assn. of Stationary Engrs.

The Firing of Steam Boilers. English Mechanic & World of Sci., vol. 108, no. 2796, Oct. 25, 1918, p. 155. Report of German patent comprising an air chamber divided by two transverse partitions and placed immediately below top portion of endless chain grate. From Zeitschrift für Dampfkessel und Maschinenenbetrieb, July 5. 1918.

Coal, Combustion Characteristics

Combustion Characteristics of Coals, Joseph G. Worker. Elec. Rev., vol. 73, no. 22, Nov. 30, 1918, pp. 849-851. Combustion characteristics of coals and their influence upon choice of stoker equipment; load conditions also important factor.

Conservation

Coal Conservation. Times Eng. Supp., no. 527, Sept. 1918, p. 187. Abstract of report of Coal Conservation Committee of Ministry of Reconstruction.

England's Fuel Rationing Order. Heat. & Vent. Mag., vol. 15, no. 11, Nov. 1918, pp. 17-21. Provisions of new regulation limiting supply of coal, gas and electricity to domestic consumers.

Fuel Regulation during the War, P. B. Noyes and D. M. Myers. Nat. Engr., vol. 22, no. 10, Oct. 1918, pp. 481-492. Discussion by Federal Government officials before Nat. Assn. of Stationary Engrs.

Industrial Coal Economy, David Wilson. Machy. Market, no. 939, Nov. 1, 1918, pp. 19-20. Suggestions based on the experience of the author who is technical advisor to Coal Controller. Paper before Assn. of Engrs.-in-charge. (To be continued.) Also in Elecn., vol. 81, no. 2110, Oct. 25, 1918, p. 540.

Proposed Coal-Rationing Rules for the United States. Heat. & Vent. Mag., vol. 15, no. 11, Nov. 1918, pp. 21-23. Allowances designed for heating, cooking and hot-water service in residences, flats and apartment houses. Final draft of report of Committee on Fuel Conservation, Am. Soc. of Heating and Vent. Engrs.

Rational Utilization of Commercial Fuels (Sur l'utilisation rationnelle des combustibles dont dispose actuellement l'industrie). Revue Générale de l'Electricité, vol. 4, no. 14, Oct. 5, 1918, pp. 505-511. Report of the Ministry of Armament and War Manufactories. From Bulletin des Usines de Guerre, Aug. 26 and Sept. 2, 1918, pp. 137-140 and 145-147.

Gasoline

Substitute for Gasoline Tested. Motor Age, vol. 34, no. 23, Dec. 5, 1918, p. 15. Excerpts of tests made by Bureau of Standards on secret product said to be composed of inexpensive and easily obtainable materials.

Hand-Fired Plants

Fuel Economy in Hand-Fired Power Plants. Power Plant Eng., vol. 22, no. 23, Dec. 1, 1918, pp. 953-956, 4 figs. Settings, stacks and breechings. Fourth article.

Load Factor

Coal Consumption Rates in Various Central Stations and Industrial Plants. Elec. Rev., vol. 73, no. 22, Nov. 30, 1918, pp. 846-848, 2 figs. Result of study by Hydro-Electric Commission of Ontario proves superiority of large power plant and emphasizes economy of high load factor.

Oil Fuel

California Petroleum as a Fuel Oil, Thomas J. Boyer. Nat. Engr., vol. 22, no. 10, Oct. 1918, pp. 525-533, 13 figs., and (discussion) pp. 533-534. Account of development; study of use in steam-boiler practice and suggestions for satisfactory operation; test in a water-works pumping station. Paper before Nat. Assn. of Stationary Engrs.

Pulverized Coal

First Pulverized Coal Installation in Western Canada, H. R. Collins. Min. & Eng. Rec., vol. 23, nos. 17 and 18, Sept. 30, 1918, pp. 177-179. Features of pulverizing plant.

Pulverized Fuel, E. R. Knowles. Steam, vol. 22, no. 5, Nov. 1918, pp. 128-133, 10 figs. Temperatures attainable; disadvantages of pulverized coal as fuel; requirements for successful burning. (Concluded.)

Pulverized Fuel in the Oneida Street Plant of the Milwaukee Elec. Ry. & Light Co., F. Dornbrook. Nat. Engr., vol. 22, no. 10, Oct. 1918, pp. 535-537, and (discussion) pp. 537-539. Results obtained with trial installation. Paper before Nat. Assn. of Stationary Engrs.

Pulverizing Coal, J. Cunliffe. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 56-58. Waste resulting from burning coal in lumps; preparation, application and burning of pulverized coal.

Waste Heat

Waste Heat from Steel Furnaces, Thomas B. Mackenzie. Times Eng. Supp., no. 527, Sept. 1918, p. 195. Method of utilizing waste heat from open-hearth furnaces in generation of steam. Paper before Iron & Steel Inst.

HANDLING OF MATERIALS

Coal

Coal-Handling Plant of Virginian Railway, E. F. Case. Ry. Rev., vol. 63, no. 21, Nov. 23, 1918, pp. 731-735, 9 figs. Account of extensive additions to this railroad's plant at Sewall's Point, Va.

Excavation Material

Comparison of Excavation Haulage by Motor Trucks, Industrial Railways and Teams. Eng. News-Rec., vol. 81, no. 22, Nov. 28, 1918, pp. 993-996, 1 fig. Detailed cost accounts on construction of Brooklyn Army Supply Base show that trucks are more economical than teams and less economical but more flexible than railways.

Grain

Car Equipment for Loading or Unloading Grain (Installations pour le transport des grains montées sur wagons). Génie Civil, vol. 73, no. 14, Oct. 5, 1918, pp. 261-263, 11 figs. Two systems: by air pressure, and by suction.

Ore

Large Ore Storage in a Limited Space, F. L. Prentiss. Iron Age, vol. 102, no. 22, Nov. 28, 1918, pp. 1311-1313, 4 figs. Double bin system of Iroquois Iron Co. solves material-handling problems and results in short haul to skip cars.

Sand

Pneumatic Car Provides Efficient Method of Handling Sand, W. L. Whitlock. Elec. Ry. Jl., vol. 52, no. 22, Nov. 30, 1918, pp. 967-968, 5 figs. By use of new sand car, crew of regular car takes care of sand transportation which formerly required services of three additional men.

HEAT TREATING

Malleable Cast Iron

Experiments in Annealing Malleable Cast-Iron, H. E. Diller. Foundry, vol. 46, no. 316, Dec. 1918, pp. 564-566, 4 figs. Results of several laboratory experiments show that malleable iron can be annealed in tunnel furnace in 48 hours or less. From paper before Am. Foundrymen's Assn., Milwaukee, Oct. 1918.

Quenching, Steel

Warping of Steel by Repeated Quenching, J. H. Whiteley. Iron Age, vol. 102, no. 21, Nov. 21, 1918, pp. 1256-1257, 6 figs. How the metal contracts; direction of its flow; interesting features revealed by microscope. From paper before Iron and Steel Inst., London, Sept. 1918.

HEATING AND VENTILATION

Equipment

Care of Heating and Ventilating Equipment, Harold L. Alt. Power, vol. 48, no. 21, Nov. 19, 1918, pp. 736-738, 3 figs. Down-draft furnace. Also in Power, vol. 48, no. 23, Dec. 3, 1918, pp. 801-803, 5 figs.

Factory Heating

Factory Heating, Charles L. Hubbard. Steam, vol. 22, no. 5, Nov. 1918, pp. 123-127, 9 figs. System of heating with hot water under forced circulation. (To be continued.)

Some Factory Heating Problems, B. C. Moore. Wood-Worker, vol. 37, no. 9, Nov. 1918, pp. 26-27. Considerations of the economical value of keeping a factory heated night and day.

Hot-Air Furnace

How to Improve the Hot-Air Furnace, Charles Whiting Baker. Department of Interior, Bureau of Mines, Tech. Paper 208, 20 figs. Recommends practice of adding auxiliary cold-air duct by which air supply to furnace may be taken from inside the house, instead of from outdoors, during very cold or windy weather.

House Heating

Economical Heating of Cottages and Small Houses, Frederick Grant. Domestic Eng., vol. 85, no. 5, Nov. 2, 1918, pp. 160-162, 4 figs. Suggests features of design for both hot-water and steam-heating systems.

Office-Building Heating

Fuel Economy in the Singer Building, Norman King. Power, vol. 48, no. 20, Nov. 12, 1918, pp. 710-711. Some figures on costs and economies.

Vapor Heating

Modern Practice in Vapor Heating. Heat. & Vent. Mag., vol. 15, no. 11, Nov. 1918, pp. 44-46, 5 figs. The Moline system. Sixth article.

Ventilation

A Discussion of Ventilating Practices, Charles A. Mitke. Coal Industry, vol. 1, no. 10, Oct. 1918, pp. 379-381. Analysis of working conditions as affected by ventilation; installation of mechanical ventilation. Paper before Nat. Safety Congress.

No Quarrel Necessary Between Natural and Mechanical Ventilation Advocates. Heat. & Vent. Mag., vol. 15, no. 11, Nov. 1918, pp. 37-40. Clear and well-defined field for each method depending upon required air conditions with given type of occupancy and occupation. From reply by E. Vernon Hill to newspaper article.

See also ELECTRICAL ENGINEERING, Power Applications (Heating); MECHANICAL ENGINEERING, Air Machinery (Air Conditioning).

HOISTING AND CONVEYING

Cranes

Handling Shipbuilding Material at Atlanta Shipyard. Eng. News-Rec., vol. 81, no. 23, Dec. 5, 1918, pp. 1020-1022, 8 figs. Planned for direct routing; three craneways in fabricating yard; shape shop in open; turret cranes at shipbuilding berths; assembly yard.

Hoisting and Conveying Machinery (Des appareils de manutention dans l'industrie en général), F. Séba. Revue Générale de l'Electricité, vol. 4, nos. 12 and 14, Sept. 21, and Oct. 5, 1918, pp. 423-433 and 493-504, 39 figs. Sept. 21: construction and arrangement of bridge cranes, traversing jib hoists, ceiling hoists, and foundry hoists. Oct. 5: traveling cranes with auxiliary crab, rollers, rails, gear shafts, drums, cables and grab hoists.

Some Heavy Fitting-Out Cranes—1. Fixed Cranes at Kearny and Hog Island Yards. Eng. News-Rec., vol. 81, nos. 20 and 21, Nov. 14 and 21, 1918, pp. 885-890, 6 figs.; 937-941, 6 figs. 100-ton trolley bridge spanning slipway supplemented by portal cranes; platform derrick of unusual capacity and reach uses single-motor hoisting engine at Hell Gate arch-erection plant. Nov. 21: 11 Cantilever and Jib Travelers at Newark Bay and Bristol; double cantilever bridge traveling along pier commands line of ships on either side; provision for extension; friction draft gear buffers; tower jib crane fitted with special safety devices.

Drums

Drum Shapes as Affecting the Mine Hoist Duty Cycle and Motor Rating, F. L. Stone. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 10, Oct. 1918, pp. 1203-1221, 22 figs. Points out that the problem of drum shape consists in varying diameter of different parts of winding drum so that load may be accelerated and retarded at beginning and end of its travel with minimum consumption of power, and gives numerical examples of performance of various drum shapes under assumed conditions.

Electric Hoisting Machines

Electric Hoisting Machines (Les machines d'extraction à commande électrique), G. Rouet. Revue Général de l'Electricité, vol. 4, no. 13, Sept. 28, 1918, pp. 451-457, 9 figs. Comparison between Léonard and three-phase types.

Ropes

Ropes for Hoisting Coal from Mines, M. W. Reed. Coal Industry, vol. 1, no. 10, Oct. 1918, pp. 388-391. Discussion concerning strength, elasticity, bending stress, starting, stopping, corrosion, clips and sockets for hoisting ropes; care and life of hoisting ropes. Paper before Nat. Safety Congress.

See also MECHANICAL ENGINEERING, Handling of Materials, Lubrication (Cranes), Machinery, Special (Hoisting Jacks)

HYDRAULIC MACHINERY

Flow of Water

A Proposed Hydraulic Experiment, Lord Rayleigh. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 214, Oct. 1918, pp. 315-316, 1 fig. Observation of flow of liquid between two cylinders revolving about their axes in opposite directions for the purpose of testing Froude's explanation regarding phenomena which take place when fluid passing along uniform pipe arrives at place where pipe expands.

Flow of Water in Wash Water Troughs for Rapid Sand Filters. Eng. & Contracting, vol. 50, no. 20, Nov. 13, 1918, pp. 461-462, 2 figs. From description in Cornell Civil Engineer of experiments made by Ernest C. Fortier and Frank V. Fields to determine surface curves for flow of water in wash water troughs and to develop formula for assistance of designers of troughs.

Flow of Water Through One- and One-Half-Inch Pipe and Valves, Frederick W. Greve, Jr. Purdue Univ., Bul. 1, Eng. Experiment Station, vol. 2, no. 2, July 1918, 21 pp. 16 figs. Tables and formulae for determining head losses incurred with use of pipes and valves.

Hydraulic Experiments with Valves, Orifices, Hose, Nozzles, and Orifice Buckets, Arthur N. Talbot, Fred B. Seely, Virgil R. Fleming and Melvin L. Enger. Univ. of Illinois Bul., vol. 15, no. 37, May 13, 1918, Bul. 105, 80 pp., 28 figs. Loss of hydraulic head in small valves; flow of water through submerged orifices; fire streams from small hose and nozzles; orifice bucket for measuring water.

Tides

Power from the Tides, J. O. Boving. Times Eng. Supp., no. 529, Nov. 1918, pp. 232-233, 6 figs. Design of turbines which author thinks will render utilization of tidal power economically feasible.

Water Hammer

Causes of Shock in Hydraulic Mains, Alfred Towler. Machy. Market, no. 942, Nov. 22, 1918, pp. 17-18. Broad consideration of cause and effect in principle of violent collision as determined by momentum. Paper before Leeds Assn. Engrs.

Maxima Excess Pressures Produced by Water Hammer (Etude sur les maxima de surpression dans les phénomènes de coups de bélier), Maurice Gariel. Revue Générale de l'Electricité, vol. 4, nos. 11 and 12, Sept. 21 and Oct. 5, 1918, pp. 403-411, 6 figs., and 483, 490, 4 figs. Analysis of modern theory of water hammer leads author to establish that Michaud's formula for maximum excess pressure applies to great majority of turbine installations; that Joukowski-Alliévi's formula applies to conduits of uniform dimensions when opening closes in less than $2\ L/a$ (where L is length in meters and a velocity of propagation of wave); and Sparre's formula in cases of non-uniform conduits and extremely rapid shut-off. Oct. 5: Investigations of phenomena of pressure waves developed in conduit by sudden release at opening and account of experimental verification of theoretical conclusions.

Waterwheels

Principles of Waterwheel Design, David R. Shearer. Power, vol. 48, no. 21, Nov. 19, 1918, pp. 732-734, 5 figs. Some of underlying principles simply illustrated, referring particularly to relation between velocity of water and the peripheral velocity of wheel.

INTERNAL-COMBUSTION ENGINES

Heavy-Oil Engines

The Diesel Engine, Its Fuels and Uses, Herbert Haas. Automotive Eng., vol. 3, no. 9, Oct. 1918, pp. 418-424. General characteristics of oil engines; three general types; various cycles and comparison of advantages of each; comparative economies; detail of construction. (To be continued.) Also in Jl. Soc. Automotive Engrs., vol. 3, no. 5, Nov. 1918, pp. 299-308, 5 figs.

The Heavy Oil Engine, Charles E. Lucke. Int. Mar. Eng., vol. 23, no. 11, Nov., 1918, pp. 625-629 (Conclusion of article.)

The Semi-Diesel Engine. Times Eng. Supp., no. 529, Nov. 1918, p. 245. Characteristics and design.

The Semi-Diesel Oil Engine, James Richardson. Engineering, vol. 106, no. 2756, Oct. 25, 1918, pp. 461-464, 12 figs. Review of many types of semi-Diesel engines. Paper before Diesel Engine Users' Asso., Oct. 24, 1918.

High-Speed Engine

Modern Types of Engines, Harry R. Ricardo, Machy. Market, no. 941, Nov. 15, 1918, pp. 17-18. Features of high-speed engine design and points upon which designers have concentrated their attention. Paper before North-East Coast Instn. of Engrs. & Shipbuilders. (To be continued.) Also in Int. Mar. Engr., vol. 23, no. 11, Nov. 1918, pp. 650-651.

Magnetos

Operation of Internal-Combustion-Engine Magnetos (Sul Funzionamento dei magneti di accensione dei motori a scoppio), Emilio Biffi. L'Elettrotecnica, vol. 5, nos. 22, 24 and 28, Aug. 5 and 25, Oct. 5, 1918, pp. 302-306, 326-332 and 386-392, 26 figs. Aug. 5 and 25: theory of the magneto-generator. Oct. 5: theory of formation of spark in secondary coil. (To be continued.)

Marine Engines

Two versus Four-Cycle Internal Combustion Marine Engines, Giovanni Chiesa. Engineering, vol. 106, no. 2757, Nov. 1, 1918, pp. 482-486, 6 figs. Purpose of article is to coordinate arguments which have been alleged for and against both types in their best form of construction and to endeavor to draw conclusion after careful consideration of all points of question.

Mixture

Mixing the Mixture, Robert Miller. Motor Boat, vol. 15, no. 22, Nov. 25, 1918, pp. 11-14, 6 figs. Points out importance of securing uniform mixture in cylinder in order to secure chemical combination and considers the problem of direct injection.

Pistons

Piston Design, Harry R. Ricardo. Automobile Engr., vol. 8, no. 119, Oct. 1918, pp. 274-278, 12 figs. Design in which connection between ring-carrying portion of piston and slipper surface is severed, so that heat can only be conducted to slipper surfaces by way of main webs, these being so constructed that heat from crown is distributed evenly over surface of slippers. Also in Autocar, vol. 41, no. 1201, Oct. 26, 1918, pp. 409-410, 3 figs.

Spark Plugs

Note on the Effect of Temperature on the Resistances of Spark Plug Insulations, J. D. Morgan. Engineering, vol. 106, no. 2758, Nov. 8, 1918, pp. 513-514, 3 figs. Description of an investigation.

See also AERONAUTICS, Engines; MECHANICAL ENGINEERING, Motor-Car Engineering (Engines, Gasoline, Kerosene, Kerosene Burning).

LUBRICATION

Cranes, Electric

Electric Crane Lubrication, Geo. R. Rowland. Lubrication, vol. 5, no. 12, Oct. 1918, pp. 2-10, 10 figs. Ring oiling system which consists of oil reservoir and brass ring attached to and revolving with shaft.

Cutting Tools

Cutting Lubricants and Cooling Liquids. Shipbuilding & Shipping Rec., vol. 12, no. 19, Nov. 7, 1918, pp. 445-446. Enumeration of factors upon which selection of suitable cutting lubricant or cooling liquid depends and suggestions in regard to their manipulation. From report issued by Advisory Council of Department of Scientific & Indus. Research.

Economy

Lubricant Economy, D. Street. Can. Machy., vol. 20, no. 22, Nov. 28, 1918, p. 617. Necessity for practicing economy and suggestions for reducing waste.

Steam Cylinders

Problems of Steam Cylinder Lubrication (III), W. F. Osborne. Blast Furnace, vol. 6, no. 10, Oct. 1918, pp. 414-416. Factors affecting operation and lubrication of compound engines.

See also MECHANICAL ENGINEERING, Motor-Car Engineering (Lubrication).

MACHINE ELEMENTS AND DESIGN

Bearings

Saving Power by Efficient Bearings, F. H. Lenox. Textile World Jl., vol. 54, no. 23, Dec. 7, 1918, pp. 91-95, 4 figs. Equipment method and results of experiments to determine power required to overcome friction of shaft bearings.

Bolts and Screws

S. A. E. Standard Screws and Bolts. Jl. Soc. Automotive Engrs., vol. 3, no. 5, Nov. 1918, pp. 333-335, 1 fig. Brief account of development of standards and comparison of standard screw-thread pitches used in five inch-systems most generally adopted in American and British practice,—B. W. S., B. S. F., U. S. S., S. A. E. Reg., S. A. E. Fine.

Crankshafts

Problems of Crankshaft Design, Otto M. Burkhardt. Aerial Age, vol. 8, no. 7, Oct. 28, 1918, pp. 376-379, 15 figs. Mathematical analysis of three groups of forces necessary to induce and maintain speeds of 3000 r.p.m. or more: pressures due to gaseous mixture, inertia forces and centrifugal forces. Paper before Eng. Soc. of Buffalo.

Gears

The Internal Gear. Pamphlet published by Fellows Gear Shaper Co., 92 pp., 55 figs. Popular presentation of the comparative tooth action of internal and external gear teeth, together with directions for cutting, and samples of applications.

See also MECHANICAL ENGINEERING, Internal-Combustion Engines (Pistons), Power Transmission.

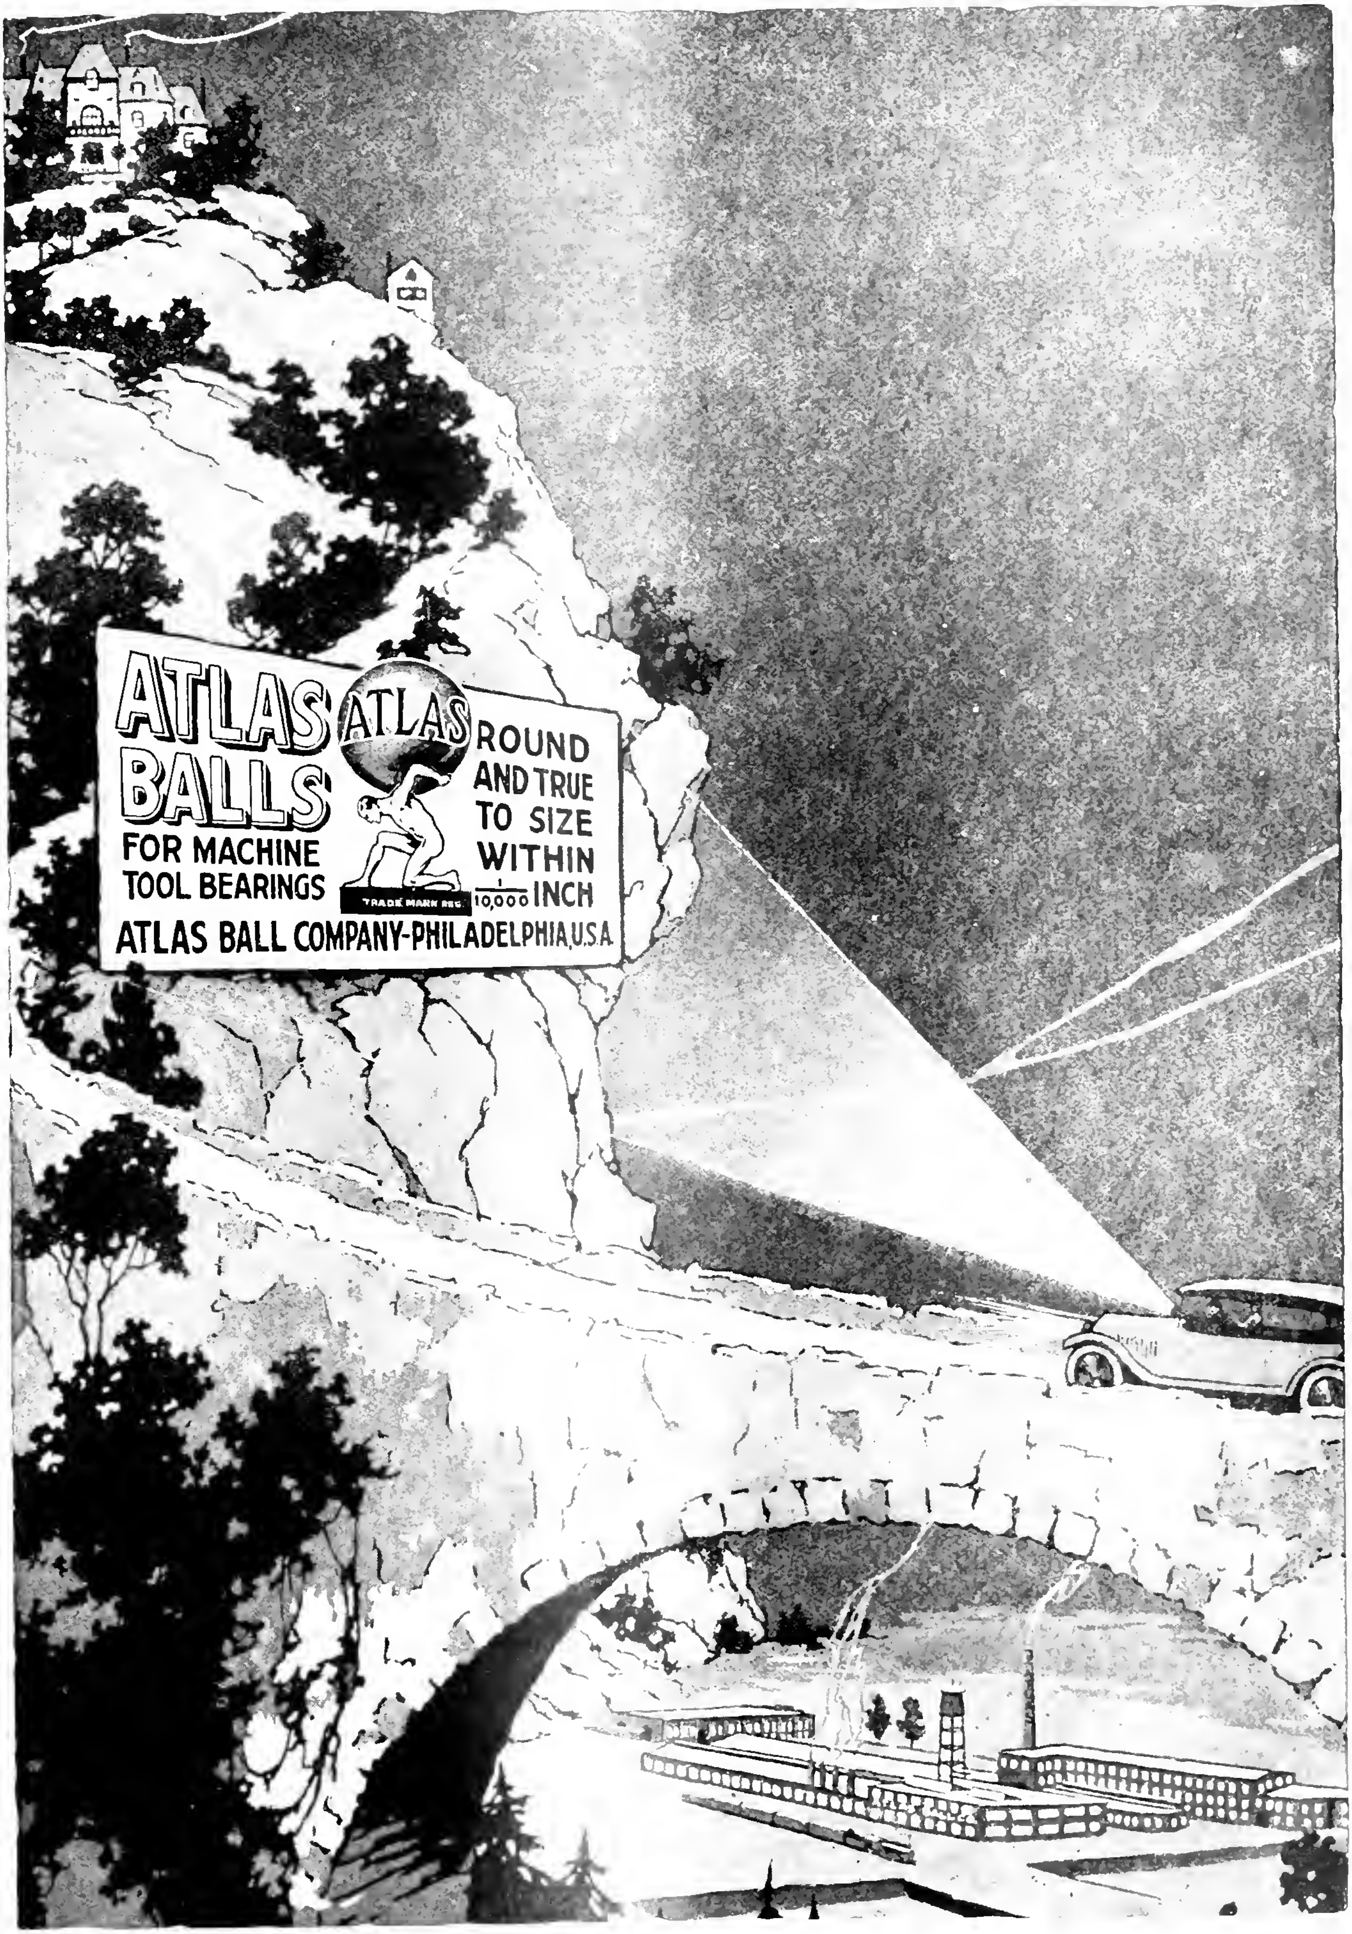
MACHINE SHOP

Tool Making

Tooling Up Single Spindle Automatics and Lathes. Can. Machy., vol. 20, no. 19, Nov. 7, 1918, pp. 536-537, 6 figs. Operations for British 101 fuse body.

Grinding

Grinding: Its Utility in the Modern Shop, D. Street. Can. Machy., vol. 20, no. 22, Nov.



ATLAS BALLS
FOR MACHINE TOOL BEARINGS
ATLAS
TRADE MARK REG.
ROUND AND TRUE TO SIZE WITHIN 1/10,000 INCH
ATLAS BALL COMPANY-PHILADELPHIA, U.S.A.

28, 1918, p. 623. Convenience of substituting grinding for tooling in certain machine operations.

Belting

Belting Speeds: Saw Speeds; Bearing Alloys, G. F. Cosgrove. Wood-Worker, vol. 37, no. 9, Nov. 1918, pp. 28-29. Account of experiments made with gang ripping machines with saws located above stock to be ripped, feed being by means of a grooved traveling bed which carries the stock beneath saws.

Drill Sharpening

Central Plant for Sharpening Drill Steels Saves Money in Quarrying. Eng. News-Rec., vol. 81, no. 21, Nov. 21, 1918, pp. 929-930, 3 figs. Sharpening shop with two men replaces five smithies; steel conveyor, oil-fired furnaces and concrete quenching vat.

Gages

Making Thread Gages, T. H. Fenner. Can. Machy., vol. 20, no. 19, Nov. 7, 1918, pp. 529-532, 7 figs. Description of plant and methods of a Canadian firm.

Milling

Continuous Milling, A. Thomas. Automobile Engr., vol. 8, no. 119, Oct. 1918, pp. 296-298, 12 figs. Notes on operation of Becker machine.

Operation

Scientific Organization of the Machine Shop (Organisation Scientifique de l'usinage), P. Denis. Génie Civil, vol. 73, nos. 12, 13 and 14, Sept. 21, 28 and Oct. 5, 1918, pp. 227-230, 246-251 and 268-271, 23 figs. Methodical execution of turning, countersinking and drilling. Sept. 21: selection of most economical cutting speed by construction of individual tool curves showing cutting speed against volume of material removed by tool at that speed before it needs resharpening. Sept. 28: further study of tool curves and their utilization in determining the most effective thermal treatment for tools used in cutting operations. Oct. 5: numerical illustrations and résumé of conclusions reached.

Punch Press

Safe Punch Press Operation, W. W. Roach. Safety Eng., vol. 36, no. 4, Oct. 1918, pp. 231-233. Discusses installation and use of mechanical guards, introduction of safe practices and education of press operators. From Proc. Seventh Annual Safety Congress.

Square Holes

Generating a Square Hole with a Gear-Shaper Cutter, Douglas T. Hamilton. Am. Mach., vol. 49, no. 21, Nov. 21, 1918, pp. 949-950, 2 figs.

Tool Department

Supervising a Large Tool Department, C. W. Starker. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 481-486. Step toward greater economy in tool department. Methods developed in tool department to coordinate requirements and minimize tool expense.

Tractor

Manufacturing the Caterpillar Tractor, Frank A. Stanley. Am. Mach., vol. 49, nos. 20, 22 and 23, Nov. 14, 28 and Dec. 5, 1918, pp. 897-901, 14 figs; 977-980, 9 figs. and 1040-1042, 12 figs. Milling work. Nov. 28: making connecting rods; Dec. 5: small parts.

See also MECHANICAL ENGINEERING, Lubrication (Cutting Tools), Welding; RAILROAD ENGINEERING, Shops.

MACHINERY, METAL-WORKING

Boring Bar

Making Boring Bars for Big Guns, M. E. Hoag. Am. Mach., vol. 49, no. 22, Nov. 28, 1918, pp. 987-988, 4 figs. Describing boring of hole 12 feet long 1¼ inches in diameter.

Grinder

Heald Cylinder Grinder. Am. Mach., vol. 49, no. 23, Dec. 5, 1918, pp. 1053-1054, 2 figs. Description of machine built by Heald Machine Co., Worcester, Mass., with principal dimensions.

Lathe

Amalgamated Shell-Turning Lathe. Am. Mach., vol. 49, no. 19, Nov. 7, 1918, p. 869, 1 fig. Short description with principal dimensions.

Slotting Machine

A New Slotting Machine of the Milling Type, J. V. Hunter. Am. Mach., vol. 49, no. 21, 1918, pp. 953-956, 9 figs. Description with principal data of new machine tool brought out by Racine Tool and Machine Co., Racine, Wis.

MACHINERY, SPECIAL

Chain

The Manufacture of Diamond Transmission Chain, J. V. Hunter. Am. Mach., vol. 49, nos. 19 and 23, Nov. 7 and Dec. 5, 1918, pp. 845-848, 9 figs, and 1027-1031, 16 figs. Making rollers; Dec. 5: Making block chain.

Rapid Development of Electric Cast Steel Anchor Chain Industry, W. L. Merrill. Int. Mar. Eng., vol. 23, no. 11, Nov. 1918, pp. 630-634, 8 figs. Electric welding versus hand welding; tests and results. Abstract of article in Gen. Elec. Rev.

Clocks

Studies in Clocks and Time-Keeping: No. 1. Theory of the Maintenance of Motion, R. A. Sampson. Proc. Roy. Soc. of Edinburgh, vol. 38, parts 1 and 2, session 1917-1918, pp. 75-114, 11 figs., and 169-218. Practical details of three clocks, Riefler, synchronome, and Cottingham; theoretical discussions on maintenance of motion, air resistance, barometric error, escapement error, temperature compensation, and other points connected with exact timekeeping. No. 2: Tables of the Circular Equation.

Evaporators

Lillie Multiple Evaporator. Steam, vol. 22, no. 5, Nov. 1918, pp. 142-143, 3 figs. Evaporator in which liquid is spread over heating surfaces in thin films.

Hoisting Jacks

Hydraulic Car Lift Gives Increased Output to Shops, Homer MacNutt. Elec. Ry. Jl., vol. 52, no. 21, Nov. 23, 1918, pp. 927-928, 4 figs. Description with illustrations of hydraulic hoisting jack.

Quarrying Machines

Labor-Saving Methods and Machines in Limestone Quarrying. Eng. & Contracting, vol. 50, no. 21, Nov. 20, 1918, pp. 478-479. From pamphlet by Oliver Bowles issued by U. S. Bureau of Mines.

Quenching Machine

A Quenching Machine for Hardening Small Drawing Dies. Am. Mach., vol. 49, no. 23, Dec. 5, 1918, pp. 1045-1046, 4 figs. Description of machine developed by S. A. Potter Tool and Machine Works, 70 East 130th St., New York.

Road Finisher

Road Finisher Produces Denser Concrete. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, p. 34, 2 figs. Machine which subjects mixture to continuous agitation by tamper.

Scales

Modern 150-Ton Track Scale Now in Use, Frank C. Perkins. Can. Machy., vol. 20, no. 19, Nov. 7, 1918, pp. 544-547, 9 figs. Mechanism of design in which plate-steel fulcrums are used.

Screens, Gravel

Comparative Analysis of Gravel Screens, Raymond W. Dull. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, pp. 21-23, 10 figs. Considers gravity, cylinder, overhung conical, and inclined conical types.

Shorthand Machine

Manufacturing a Shorthand Machine, M. E. Hoag. Am. Mach., vol. 49, nos. 19, 20 and 21, Nov. 7, 14 and 21, 1918, pp. 853-854, 8 figs., 902-904, 8 figs, and 946-947, 8 figs. Describing mechanical features of machine, some tools and dies. (First article.)

Tool Setter

Alignment-Tester and Microscopic Tool-Setter. Engineering, vol. 106, no. 2754, Oct. 11, 1918, pp. 398-399, 7 figs. Description of an instrument constructed by Cambridge Scientific Instrument Company, Limited, Cambridge.

See also CIVIL ENGINEERING, Roads and Pavements (Mixers).

MATERIALS OF CONSTRUCTION AND TESTING OF MATERIALS

Asphalt

Standardization of Required Consistency for Asphalt, J. R. Draney. Contract Rec., vol. 32, no. 46, Nov. 13, 1918, p. 910. Quotes present variations and suggests possible specifications.

Boiler Plate

Materials of Steam Boiler Construction, A. J. Dixon. Boiler Maker, vol. 18, no. 11, Nov. 1918, pp. 317-319. Action of carbon in boiler plate; dangers of free use of cast iron; laminar structure of wrought iron. From Power.

Cracks

Prevention of Season and Corrosion Cracks, W. B. Price. Am. Mach., vol. 49, no. 19, Nov. 7, 1918, pp. 848-850, 7 figs. Paper before Am. Soc. for Testing Materials, Atlantic City, June 1918.

Monel Metal

Note on Monel Metal, John Arnott. Engineering, vol. 106, no. 2756, Oct. 25, 1918, p. 451, 3 figs. Composition, microstructure, strength of rolled materials, effect of annealing strength at high temperature, use.

Silica Brick

Silica Brick Tests. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, p. 62. Brief report of experiments conducted in France which revealed that notable quantities of iron oxide do not sensibly lower fusing point of silica, even when lime is present.

See also CIVIL ENGINEERING, Materials of Construction; AERONAUTICS, Materials of Construction.

MEASUREMENTS AND MEASURING APPARATUS

Depth Gage

A Micrometer Depth Gauge, C. H. Copland. Model Engr., vol. 39, no. 914, Oct. 31, 1918, pp. 239-240, 6 figs. General arrangement and details of gage intended for use on munition or other fine work.

Hardness

The Institution of Mechanical Engineers. Engineering, vol. 106, no. 2756, Oct. 25, 1918, pp. 469-472, 5 figs. Discussion of three papers on hardness testing, "A Law Governing the Resistance to Penetration of Metals When Tested with a 10-mm. Steel Ball; and a New Hardness Scale in Energy Units," by Prof. C. A. Edwards, "The Value of the Indentation Method in the Determination of Hardness," by R. G. C. Batson, and "The Ludwik Hardness Test," by W. C. Unwin, all read at meeting of Inst., Oct. 1918.

The Ludwik Hardness Test, W. C. Unwin. Engineering, vol. 106, no. 2756, Oct. 25, 1918, p. 478. Paper before Inst. of Mech. Engrs., Oct. 1918.

The Resistance of Metals to Penetration Under Impact, C. A. Edwards. Engineering, vol. 126, no. 3276, Oct. 11, 1918, pp. 314. Abstract of paper before Inst. of Mech. Engrs., June 1918.

Value of the Indentation Method in the Determination of Hardness, R. G. C. Batson. Engineering, vol. 106, no. 2756, Oct. 25, 1918, pp. 475-477, 6 figs. Paper before Inst. of Mech. Engrs., Oct. 1918.

Heat Measurement

Heat-Measuring Instruments, C. E. Clewell. Am. Mach., vol. 49, no. 23, Dec. 5, 1918, pp. 1021-1025, 12 figs. Principal types of pyrometers; features connected with their use; typical uses; cases of practical installations of pyrometers illustrated.

Indicators

Indicator Cord Connections, R. T. Strohm. Southern Engr., vol. 30, no. 4, Dec. 1918, pp. 40-41, 7 figs. Collection of methods used by engineers to connect cord to reducing motion.

Minimeter

The Minimeter for Fine Measuring, Frank C. Perkins. Can. Machy., vol. 20, no. 21, Nov. 21, 1918, pp. 592-593, 5 figs. Principle and forms of Hirth apparatus for measuring threads, balls, cylindrical parts and grooves, also for inside measuring of various diameters.

Permeability

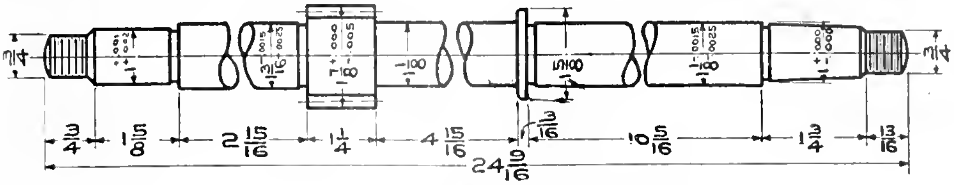
Determination of Permeability of Balloon Fabrics, Junius David Edwards. Aeronautics, vol. 15, no. 261, Oct. 16, 1918, pp. 358-364, 7 figs. Theory of process; volume-loss methods; penetration methods; experimental apparatus; effect of experimental conditions on apparent permeability; operating directions and calculations. From Aviation & Aeronautical Eng.

Variance

Variance of Measuring Instruments and Its Relation to Accuracy and Sensitivity, Frederick J. Schlink. Jl. Franklin Inst., vol. 186, no. 6, Dec. 1918, pp. 743-747. Abstract of notes from U. S. Bureau of Standards.

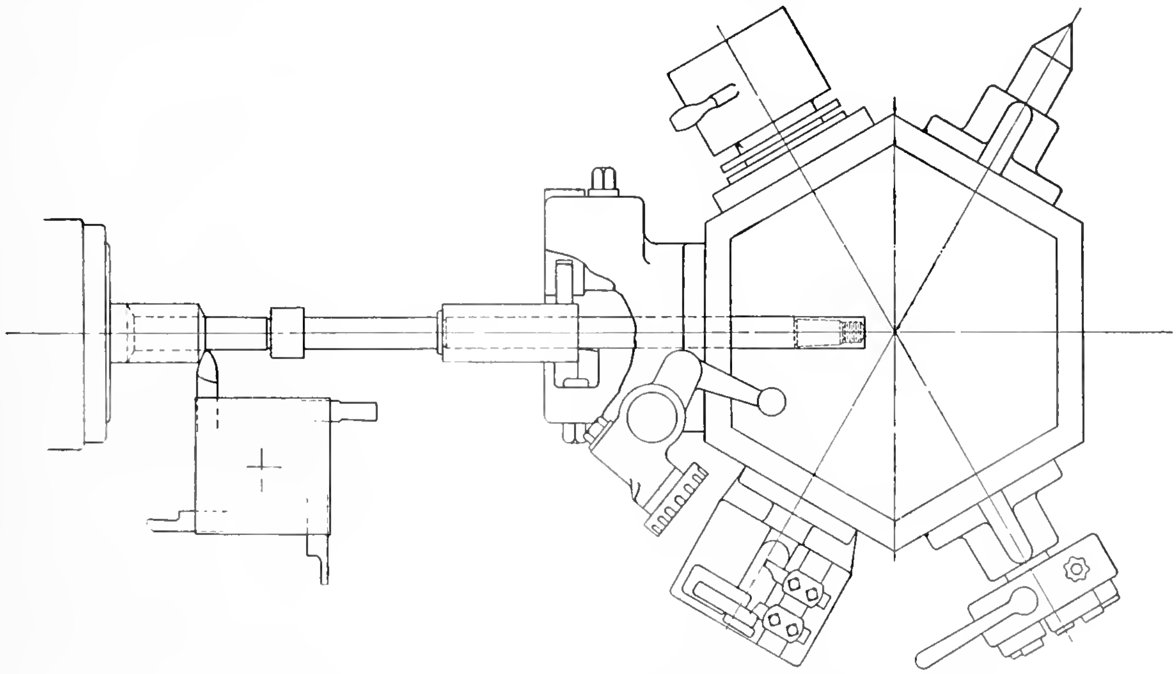
Viscosity

On the Measurement of the Viscosity of Liquids (Sur la mesure de la viscosité des huiles), C. Chéneveau. Journal de Physique, vol. 7, May-June 1917, pp. 109-114, 1 fig. Apparatus for measuring absolute viscosity by application of Poiseuille's law.



Follow This Thru

YOU will spend your time profitably by analyzing each operation in producing this shaft on the No. 2-A Universal Hollow Hexagon Turret Lathe.



1st Operation:—Turn the 1⅛ in. diameter with the turning tool. At the same time, with a cutter in the square turret, form the 1⅝ in. shoulder and turn the 1⅛ in. diameter behind the shoulder. With another square turret cutter, turn the 1⅞ in. and 1 3-16 in. diameter. The two turrets finishing their work simultaneously.

2nd Operation:—Turn the ¾ in. diameter.
3rd Operation:—Center Shaft.
4th Operation:—Turn the 1 in. tapered diameter with taper attachment and nick with square turrent cutter.
5th Operation:—Thread ¾ in. diameter.
6th Operation:—Cut off.

Warner & Swasey turret lathes will mean sure profits to you. Send blueprints for an analysis like the shaft job here.

MECHANICS

Beams

Curved Beams. James J. Guest. Proc. Roy. Soc., vol. 95, no. A665, Sept. 2, 1918, pp. 1-21, 6 figs. Determination of stresses produced by bending moment in uniform curved beams of several special sections; method of estimating maximum stress applicable to sections considered and approximately to any other section not having extraordinary features.

The Buckling of Deep Beams. J. Prescott. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 214, Oct. 1918, pp. 297-314, 7 figs. Attempt to develop mathematical theory of side buckling of beam having a depth much greater than its breadth by assuming buckling has actually occurred and finding value of couples at end which will maintain buckled state of beam.

Elasticity

Elastic Solids Under Body Forces. D. N. Mallik. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 214, Oct. 1918, pp. 321-326. Derives from equation of equilibrium of isotropic solid under body forces mathematical expression for its displacement.

Theory of Elastic Phenomena Taking Place in Punching and Drawing of Plastic Blocks (Théorie du poinçonnage et de l'écoulement des blocs plastiques: phase elastique de ces phénomènes). J. Boussinesq. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 15, Oct. 7, 1918, pp. 505-510. Studies general case of cylindrical block. Supplement to four previous communications (Comptes rendus, vol. 167, July 29, Aug. 5, 12, 19, pp. 186, 221, 253, 285) on the verification of Trosca's formulæ.

Shafts

The Periods of Lateral Vibration of Loaded Shafts—The Rational Derivation of Dunkerley's Empirical Rule for Determining Whirling Speeds. H. H. Jeffcott. Proc. Roy. Soc., vol. 95, no. A666, Oct. 7, 1918, pp. 106-115. Derives Dunkerley's rule by investigating conditions in uniform and light shaft freely supported by bearings at its ends, and loaded with discrete masses m_1, m_2, ... m_n, of negligible moment of inertia at definite points along its length. Then by considering several successively higher whirling speeds of loaded shaft, the degree of approximation of Dunkerley's rule is determined.

Springs

A New Theory of Plate Springs. David Landau and Percy H. Parr. Jl. Franklin Inst., vol. 186, no. 6, Dec. 1918, pp. 699-721, 8 figs. Mathematical study of effect of tapering ends of leaves on strength of spring. Continued from vol. 185, April 1918, p. 481. (To be continued.)

Tubes

Contribution to Our Knowledge on Calculation of Stresses in Tubes (Bidrag till Kännedom om tubers beräkning). Folke L:son Grange. Teknisk Tidskrift, Väg—och Vatten-Byggnadskonst, year 48, no. 10, Oct. 1918, pp. 145-147, 4 figs.

MOTOR-CAR ENGINEERING

Design

Aeronautical Experience Will Profoundly Affect Motor Car Practice. A. A. Remington. Automotive Ind., vol. 39, no. 18, Oct. 31, 1918, p. 776. Emphasizes necessity for greater standardization and more research work. Presidential address before British Instn. Automobile Engrs.

Post-War Chassis. Automobile Engr., vol. 8, no. 119, Oct. 1918, pp. 279-280. Possible effects of aircraft engine experience and other factors bearing upon design. (To be continued.)

Engines, Gasoline

The "American" Sleeve-Valve Motor. Auto. vol. 23, no. 44, Nov. 1, 1918, pp. 820-822, 6 figs. How sleeves are operated; suggestion to overcome tendency not to get rid of exhaust, by offsetting forward sleeve exhaust port from its present direct opposition to inlet and narrowing and deepening both it and others corresponding in cylinder wall and in head.

Engines, Kerosene

Beaver Kerosene Tractor Engines. Automotive Industries, vol. 39, no. 20, Nov. 14, 1918, pp. 839 and 862, 2 figs. Horsepower and torque curves of 4¾ × 6-in. engine and record of 5 hr. endurance test on full-open throttle at 900 r.p.m.

Fuel Consumption

Tests for Reducing Fuel Consumption on Motor Vehicles (Forsog paa Besparelse af Brændselsolie ved Automobilkorsel). Paul Bergsoe. Ingeniøren, year 27, no. 85, Oct. 23, 1918, pp. 557-558.

Gas Fuel

Coal Gas for Motor Vehicles. Times Eng. Supp., no. 527, Sept. 1918, p. 187. Modifications for running under compressed charges introduced by London General Omnibus Co.

Kerosene Burning (see Engines, Kerosene)

Kerosene Vaporization. L. E. French. Automotive Industries, vol. 39, no. 20, Nov. 14, 1918, p. 845, 2 figs. Apparatus embodying tube and hot-spot systems of vaporizing heavy fuel for internal-combustion engines, the two effects being automatically balanced.

The Bellem-Bregeras Kerosene Atomizer. Auto. vol. 23, no. 45, Nov. 8, 1918, p. 845, 2 figs. Theoretical value and practical performance results.

Lubrication

Lubrication and Fuel Tests. P. J. Dasey. Automotive Ind., vol. 39, no. 21, Nov. 21, 1918, pp. 875-877, 4 figs. Deals with tests made on a Buda tractor-type engine. Devorik's new synthetic gasoline. Paper before section of Soc. Automotive Engrs.

Single-Feed System Oils Car from Seat. Automotive Ind., vol. 39, no. 17, Oct. 24, 1918, p. 719. Multiple-plunger hand pump and reservoir constructed to supply oil under pressure to all points on chassis.

Steam Vehicles

Solid Fuels for Steam Vehicles. Motor Traction, vol. 27, no. 709, Oct. 2, 1918, pp. 243-244. Review of tests conducted by coal controller to prove that other fuels than Welsh coal could be used.

Tractors

Heider Friction Drive Tractor. Automotive Industries, vol. 39, no. 20, Nov. 14, 1918, pp. 831-832, 4 figs. Friction drive which enables a considerable number of tractor speeds and belt speeds to be obtained without use of shifting gears.

Wheels

Front Wheel Wobble. Walter Boyle. Motor Traction, vol. 27, no. 712, Oct. 23, 1918, pp. 305-306, 2 figs. Sketch of method to give trailing effort to front wheels by tilting steering heads.

PIPE

Tile

Tile Pipe Versus Iron Pipe for Drains. Osborne Smith. Contract Rec., vol. 32, no. 44, Oct. 30, 1918, p. 873. Brief account of author's experience and suggestions in regard to jointing.

POWER GENERATION

Canada

Utilizing Canada's Water Powers. J. B. Challies. Can. Mfr., vol. 38, no. 8, Aug. 1918, pp. 25-27. Future possibilities and requirements for their realization. From paper before Can. Soc. Civil Engrs.

POWER PLANTS

Boiler Inspection

Ontario Boiler Inspection Office. Power, vol. 48, no. 20, Nov. 12, 1918, pp. 698-699, 13 figs. Examples of dangerous conditions found in boilers described and illustrated.

Boiler Operation

Boiler Room Efficiency. A. H. Blackburn. Power Plant Eng., vol. 22, no. 22, Nov. 15, 1918, pp. 919-920. Analysis of fuel; losses in boiler room; instruments; coal handling. Abstract of paper before Annual Convention of Smoke Prevention Assn.

Economic Operation of Steam Turbo-Electric Stations. C. T. Hirshfeld and C. L. Karr. Department of Interior, Bureau of Mines, Tech. Paper 204, 29 pp., 5 figs. Analysis of methods used in boiler room for producing steam required and distributing load between main units available. Discussion of economic source for auxiliary power and conclusion that auxiliary power in excess of that obtainable with exhaust steam absorption can be procured from main generators in electrical form at lower thermal cost than in any other way.

Economical Working of Boiler Plant. P. D. Kirkman. Machy. Market, no. 942, Nov. 22, 1918, p. 18. List of modern efficiency apparatus and of items to be studied in connection with waste and efficiency. Address to Manchester Branch of British Assn. of Textile Managers.

Economy in Boiler Operation. Thomas M. Gray. Southern Engr., vol. 30, no. 4, Dec. 1918, pp. 42-43, 1 fig. Advantages and disadvantages of high furnace temperatures; conditions produced by forcing boilers considerably beyond their rating; sampling and analyzing of flue gases.

Boiler Settings

Boiler Setting Radiation and Air Leakage. E. S. Hight. Elec. World, vol. 72, no. 21, Nov. 23, 1918, pp. 974-975, 1 fig. Results of experiments to determine best method of covering boiler settings to bring about reduction in radiation and escape of air; type of covering which saves $1000 per 500-hp. battery per year.

Central Stations

A Kilowatt Hour and the Coal Required to Produce It. B. H. Blaisdell. Elec. Eng., vol. 52, no. 2, Aug. 1918, pp. 26-28. Waste inherent in present system of generating power and remarks on some of the losses due to imperfect manipulation. Paper before Manila Section of Nat. Elec. Light Assn.

Increasing the Economy of Central-Station Operation. J. W. Andree. Elec. World, vol. 72, no. 19, Nov. 9, 1918, pp. 881-882. Overhauling water conduits and prime movers; burning natural gas to save fuel oil; other proved methods.

Coke-Oven Plants

Power Plants at By-Product Coke-Ovens. F. E. Harris. Ir. & Cl. Trds. Rev., vol. 96, no. 2617, April 26, 1918, pp. 450-452, 2 figs. Discusses requirements and how to obtain satisfactory results.

Condensers

Condensers and Condenser Engineering Practice. D. D. Pendleton. Power, vol. 48, no. 20 and 21, Nov. 12 and 19, 1918, pp. 720-722 and 756-757. Abstract of paper presented at twelfth annual convention of Assn. of Iron and Steel Elec. Eng., Baltimore, Sept. 1918.

Cost

Improving Factory Steam Plants (V). H. A. Wilcox. Power Plant Eng., vol. 22, no. 22, Nov. 15, 1918, pp. 915-918, 2 figs. Test to determine proper division of costs; schedule of operation for power department.

Economizers

Exact Data on the Running of Steam Boiler Plants. D. Brownlie. Engineering, vol. 106, no. 2757, Nov. 1, 1918, pp. 481-482. Economizers. First article.

Efficiency

Steam Plant Efficiency. Coal Trade Jl., year 50, no. 49, Dec. 4, 1918, pp. 1433-1434. Suggestions addressed operating officers, superintendents, chief engineers, motive power department officials and men in charge of stationary power, heating and pumping plants by U. S. Railroad Administration.

Exhaust Steam

Maintenance of a Proper Heat Balance. R. N. Ehrhart. Power, vol. 48, no. 20, Nov. 12, 1918, pp. 692-694, 4 figs. Describing band and automatic control of exhaust steam from auxiliaries so that quantity of exhaust steam available for feed heating may at all times be proportioned to load on main units, thus preventing waste of exhaust at light loads.

High-Pressure Steam

The Use of High-Pressure and High-Temperature Steam in Large Power Stations. J. H. Shaw. Inst. E. E., Nov. 1918, pp. 1-10, 5 figs. From the point of view of the engineer interested in the generation of electricity. Also in Machy. Market, no. 942, Nov. 22, 1918, pp. 19-20.

Individual Plants

New General Electric Steam Turbine Shop. F. L. Prentiss. Iron Age, vol. 102, no. 20, Nov. 14, 1918, pp. 1195-1199, 6 figs. Construction and other features in large plant designed for heavy machine work; production methods followed.

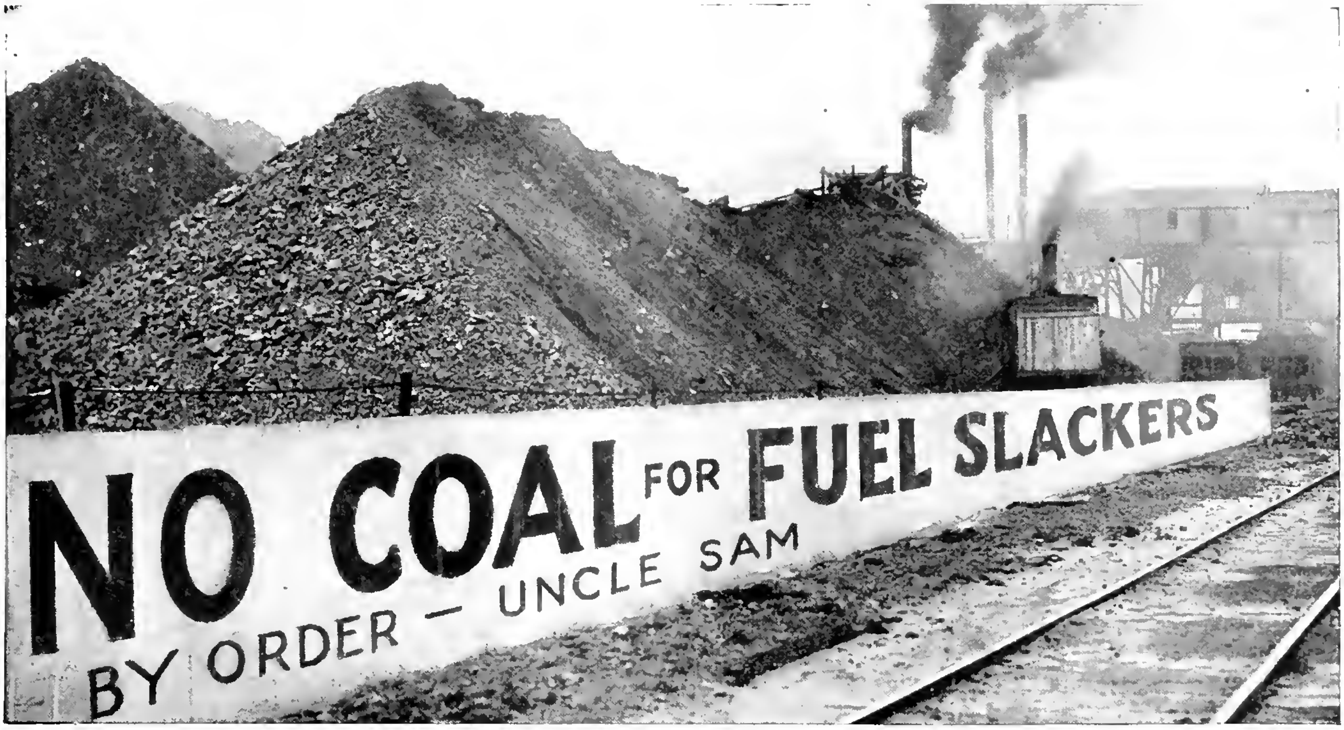
Plant Arrangement and Cost of Construction. Elec. World, vol. 72, no. 19, Nov. 9, 1918, pp. 888-890, 3 figs. Features of latest station of Turners Falls Power & Electric Co., may become one of most important steam plants in New England. (Second article.)

Instruments

Power Plant Management—(IV) The Use of Instruments. Robert June. Refrigerating World, vol. 53, no. 10, Oct. 1918, pp. 23-26, 7 figs. Importance of using recording instruments; graphs showing draft required at different combustion rates for various fuels, loss due to unconsumed carbon contained in CO_2 in flue gases, and loss due to heat carried away by chimney gases for varying percentages of CO_2.

Power Industry

Conditions in the Power Industry. Ludwig W. Schmidt. Power, vol. 48, no. 23, Dec. 3,



How "85% Magnesia" Saves the Nation's Coal Pile

If every steam pipe and every boiler were properly protected from heat losses by an efficient heat insulation, *enough coal would be saved* to furnish, not only to our vital industries, but to every coal user in the country, an *ample supply for all his needs.*

Are You a Fuel-slacker?

Are you heeding the urgent call of the Fuel Administration for the utmost economy in coal consumption, or are you robbing the nation's coal pile in order to cover your own neglect? Sooner or later you must answer this question. *What will your answer be?*

The Fuel Administration Says:

"The Fuel Administration realizes that *adequate insulating covering* is essential to the conservation of our all too scant fuel production."

It also says:

"Covering these surfaces with '85% Magnesia'...2" thick will save 80 per cent of the heat."

Are You Prepared?

Dare you say that every steam pipe and boiler in your plant is so thoroughly protected against heat wastage by the best possible insulation, that further economy is impossible? Is there no waste from your valves, flanges, or fittings? Is every feed water pipe, every feed heater, every auxiliary installation, similarly protected?

The Time for "85% Magnesia" is Now

"85% Magnesia" properly applied will bring down your coal losses due to heat-leakage to an irreducible minimum. This fuel economy not only benefits the nation but puts good money into your own pocket.

Not only does "85% Magnesia" save from 80% to 95% of all the heat that would otherwise be wasted, but its marvelous *durability* makes it the most paying investment in your plant:—(1) Because it saves its own cost in a few months; (2) Because this saving continues indefinitely—there is no known time-limit to the life of this insulation.

If you haven't "85% Magnesia" coverings throughout your Plant, *install them now*—not only on pipes and boilers, but on valves, fittings, flanges and feed heaters. If you already have insufficient thickness of Magnesia, overlay it with another thickness, according to the exact Table in the Magnesia Association Specification, compiled and indorsed by the Mellon Institute of Industrial Research, which gives exact rules for application of this master heat-insulation—*sent on request.*

Also write for Table showing monthly saving in dollars and cents by the use of "85% Magnesia."

MAGNESIA ASSOCIATION *of* AMERICA

721 Bulletin Bldg.
Philadelphia
Penna.

EXECUTIVE COMMITTEE, Wm. A. Macan, *Chairman*

1918, pp. 798-800. Digest of reports of U. S. consuls on power situation in various parts of world and influence of war upon this industry.

The Power Plant Problem in South China, Harold B. Wilson. Power, vol. 48, no. 21, Nov. 19, 1918, pp. 747-748. Only pioneer work has been done and there is opportunity for America in this field.

Scale

Heat Loss Due to Scale. Can. Mfr., vol. 38, no. 8, Aug. 1918, p. 31, 1 fig. Chart showing approximate annual loss with coal at different prices.

Screens, Water

Screening Condensing Water Efficiently and Economically, Henry J. Edsall. Steam, vol. 22, no. 5, Nov. 1918, pp. 133-137, 7 figs. Describes traveling screens with automatic cleaning features.

Stack Losses

Steam Plant Efficiency, Henry Kreisinger. Coal Trade Jl., year 50, no. 47, Nov. 20, 1918, pp. 1392-1393. Causes of high ash loss; methods of determining stack losses; causes of large excess of air and remedy. (To be concluded.)

Temperature Regulation

Automatic Temperature Regulation as a Fuel Conservation Measure. Heat. & Vent. Mag., vol. 15, no. 11, Nov. 1918, pp. 40-43. Advanced report of a Committee on Automatic Heat Control, as furnished to Fuel Administration. For presentation at annual meeting of Am. Soc. of Heating and Vent. Engrs., New York, Jan. 1918.

Water Softening

Home-Made Water Softening Plant, H. D. Odell. Power, vol. 48, no. 21, Nov. 19, 1918, pp. 728-731, 3 figs. Description of home-made water-softening plant and experiences with it.

Wire-Making Plants

Power Generation for Wire Making. Power Plant Eng., vol. 22, no. 22, Nov. 15, 1918, pp. 907-914, 15 figs. Description of plants of John A. Roebling Sons Co., Trenton, N. J.

See also ELECTRICAL ENGINEERING, Generating Stations.

POWER TRANSMISSION

Gears

Saving Coal at the Gear and Wheel Tread, C. W. Squier. Elec. Ry. Jl., vol. 52, no. 20, Nov. 16, 1918, pp. 876-878, 7 figs. Discussion of losses in gearing; showing how correct gear ratio with low armature speed will save power; comparing gearless and geared motors and two and four motor equipments.

PRODUCER GAS

Machine Shop for Gas Producer Work. Iron Age, vol. 102, no. 23, Dec. 5, 1918, pp. 1373-1378, 14 figs. Features of new plant of Smith Gas Engineering Co., Dayton, Ohio. Producer operation for power purposes.

REFRIGERATION

Ammonia Compression

Improving a Refrigerating Plant, E. W. Miller. Refrigerating World, vol. 53, no. 9, Sept. 1918, pp. 25-26, 1 fig. Account of work done in installation consisting of a 50-ton horizontal double-acting compressor, a 150-hp. combination fire- and water-tube boiler, pumps and a 50-kw. generating unit.

The Ammonia Compression Refrigerating System (XXII), W. S. Doan. Refrigerating World, vol. 53, no. 9 and 10, Sept. and Oct. 1918, pp. 31-32, 3 figs. and 31-32, 3 figs. Troubles likely to develop in piston-rod stuffing box and manner of overcoming them.

Ammonia Leakage

Finding "Lost" Ammonia in Refrigerating Plants, E. W. Miller. Power, vol. 48, no. 21, Nov. 19, 1918, pp. 734-735. Common causes for leakage of ammonia.

Ice Plants

Ice Plant Troubles, E. W. Miller. Southern Engr., vol. 30, no. 4, Dec. 1918, pp. 48-50. Outline of conditions in actual case and suggestions on economical operation.

Operation

Making a Neglected Refrigerating Plant Give Capacity, E. W. Miller. Power, vol. 48, no. 23, Dec. 3, 1918, pp. 810-811, 1 fig. What was done to make comparatively new plant give rated capacity.

Small Machines

Small Refrigerating Machines, John E. Starr. Refrigerating World, vol. 53, no. 9, Sept. 1918, pp. 11-12. Difficulties presented by small machines in addition to the difficulties existing in all machines.

RESEARCH

The National Engineering Societies and the National Research Council, Geo. Ellery Hale. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 10, Oct. 1918, pp. 1223-1236. War duties; present organization of research information service; international coöperation in research.

See also ELECTRICAL ENGINEERING, Measurements and Tests (Official Testing Laboratories).

STANDARDS AND STANDARDIZATION

Metric System

The Metric System, Harry Allcock. Surveyor, vol. 54, no. 1399, Nov. 8, 1918, p. 227. Criticism of arguments presented by Committee on Commercial and Industrial Policy After the War in their report against early introduction of metric system.

Use of the Metric System in the United States. Sci., vol. 48, no. 1248, Nov. 29, 1918, pp. 540-541. Resolution adopted by United States Section of International High Commission regarding use of metric system in U. S. in order to foster Pan-American commercial relations.

Screw Threads

Inaugural Presidential Address to the Manchester Association of Engineers. Steamship, vol. 20, no. 353, Nov. 1918, pp. 112-115. Consideration of various aspects of problem of standardizing screw threads and other industrial products.

STEAM ENGINEERING

Boilers

Safe Working Pressure for Steam Boilers, H. F. Gauss. Power, vol. 48, no. 22, Nov. 26, 1918, pp. 772-774. Simple treatment dealing with efficiency of riveted joints, bursting and safe working pressures for boilers, and permissible pressure on stayed surfaces.

How to Design and Lay Out a Boiler (I), Wm. C. Strott. Boiler Maker, vol. 18, no. 11, Nov. 1918, pp. 311-313, 4 figs. Formula for safe working pressure; maximum ultimate tensile strength for steel; factors of safety. (To be continued.)

Exhaust Steam

Commercial Value of Exhaust Steam, Frederick C. Ruck. Nat. Engr., vol. 22, no. 10, Oct. 1918, pp. 498-507. Data from actual observations and practical experience covering a period of several years. Paper before Nat. Assn. of Stationary Engrs.

Turbine Gives Additional Line Shaft Power. Blast Furnace, vol. 6, no. 10, Oct. 1918, pp. 430-432, 1 fig. Possibilities for expansion by use of exhaust steam in low-pressure turbines; efficiency of reduction gears.

Straight-Flow Engines

Details of Construction of Straight-Flow Steam Engines (Constructie-details van gelijkstroom-stoommachines), D. A. De Fremery. De Ingenieur, year 33, no. 42, Oct. 19, 1918, pp. 807-817, 23 figs.

Turbines

Avoiding Distortion in Turbine Operation, Webster Tallmadge. Power, vol. 48, no. 22, Nov. 26, 1918, pp. 762-765, 8 figs. Explaining some of careless treatments afforded steam turbines through ignorance and thoughtlessness and how to avoid them.

Care in the Operation of Small Turbines, J. A. MacMurchy. Power, vol. 48, no. 21, Nov. 19, 1918, pp. 744-745. Parts of small steam turbine which should receive particular attention.

The Steam Turbine (IX). Southern Engr., vol. 30, no. 4, Dec. 1918, pp. 52-53, 3 figs. Installation, operation and maintenance of Terry steam turbine. (To be continued.)

Tool, L. W. Schmidt. Am. Mach., vol. 49, no. 20, Nov. 14, 1918, pp. 893-896. Electric power and industrial development; possibilities for American trade; difficulties to overcome.

Engineers' Act on Status of

Draft of Proposed Act for Engineers. Jl. Eng. Inst. Can., vol. 1, no. 7, Nov. 1918, pp. 331-332. Wording of Act proposed in province of Saskatchewan defining the status of the engineer.

Handles

The Uses of Wood (VII), Hu Maxwell. Am. Forestry, vol. 24, no. 299, Nov. 1918, pp. 679-687, 15 figs. Woods used in manufacture of handles.

Logging

Filling the Allies' Rush Order for Airplane Spruce, Nathan A. Bowers. Eng. News-Rec., vol. 81, no. 23, Dec. 5, 1918, pp. 1023-1031, 11 figs. Best talent of country assembled to develop methods new to logging and sawmill practice; 13 railroads built and 100,000 workers coördinated.

Pliers

Manufacturing Drop-Forged Pliers, Ellsworth Sheldon. Am. Mach., vol. 49, no. 20, Nov. 14 1918, pp. 889-893, 14 figs. Describing operations involved in manufacture of drop-forged pliers.

Electrical Engineering

ELECTROCHEMISTRY

Electrolytes

The Abnormality of Strong Electrolytes. II. The Electrical Conductivity of Non-Aqueous Solutions, Jnanendra Chandra Ghosh. Jl. Chem. Soc., vols. 113 and 114, no. 670, Aug. 1918, pp. 627-638. Application to non-aqueous solutions of author's equation derived from modification of Maxwell's equation of distribution of velocities.

Reduction of Metals

Electric-Furnace Reduction of Certain Metals Susceptible of Industrial Utilization (Sur la preparation au four électrique de quelques métaux susceptibles d'utilisation industrielle), Jean Escard. Revue Générale de l'Electricité, vol. 4, no. 11, Sept. 14, 1918, pp. 375-386, 3 figs. Notes on reduction of barium, calcium, glucinum, cobalt, nickel, titanium, manganese, chromium, molybdenum, tungsten, vanadium.

ELECTROPHYSICS

Distribution, Electrostatic

The Electron Theory of Metallic Conductors Applied to Electrostatic Distribution Problems, L. Silberstein. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 215, Nov. 1918, pp. 413-420. General expression for equilibrium distribution in terms of total charge and potential of external field, and application of general formula to cases of full spherical conductors and hollow sphere.

Electrospherical Functions

Electrospherical Functions Expressed as Determinants (Les fonctions électrosphériques sous forme de déterminants), Pierre Humbert. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 12, Sept. 16, 1918, pp. 428-430. Expresses three electrospherical polynomials in terms of determinants of order p for the first two and the order $p+1$, for the last. Also in Revue Générale de l'Electricité, vol. 4, no. 18, Nov. 2, 1918, pp. 651-652; Annales de Physique, vol. 9, series 9, 1918.

Periodic Currents

Oscillating Energy (Energie oscillante), G. Szarvady. Revue Générale de l'Electricité, vol. 4, no. 12, Sept. 21, 1918, pp. 411-422, 2 figs. Application of Ohm's law and Kirchhoff's laws to watt currents and wattless components of electromotive forces and intensities of periodic currents.

Saturation

On the Calculation of Magnetic and Electric Saturation Values, J. R. Ashworth. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 214, Oct. 1918, pp. 351-360. Deduces $I_0 = \sqrt{(R/R^1)}$ where I_0 is limiting intensity of magnetization, R the gas constant and R^1 the reciprocal of the product of susceptibility into absolute temperature; also ($i_0 = \sqrt{(R/S)}$, where i_0 is maximum current density a conductor can carry, S ratio of resistivity to absolute temperature and V the velocity of electron as it passes along conductor.

Vacuum Phenomena

Rectification by Vacuum Discharge (in Japanese), T. Kujirai. Denki Gakkwai Zasshi, no. 361, Aug. 31, 1918.

Theory of Coolidge Tube (Sur la théorie du fonctionnement du tube Coolidge à radiateur), A. Dauvillier, Revue Générale de l'Electricité, vol. 4, no. 13, Sept. 28, 1918, pp. 443-445. Explains increase in resistance by presence of large quantity of oxygen liberated at focus and by partial oxidation of filament, together with formation of double layer which diminishes electronic emission.

Vibration, Mechanical, Generating Electrical Energy

Experiments on the Effect of the Vibration of a Stretched Wire Forming Part of a Closed Electric Circuit, Henry Jackson. Proc. Roy. Soc., vol. 95, no. A665, Sept. 2, 1918, pp. 51-57. Experiments with sensitive telephone detector which in author's judgment confirm Marran's suggestion that a mechanical vibration or note produces electricity.

GENERATING STATIONS

Alternators in Parallel

Synchronizing Alternators Coupled in Parallel (La mise en phase dans le couplage en parallèle des alternateurs), Eilvind Styff. Revue Générale de l'Electricité, vol. 4, no. 13, Sept. 28, 1918, pp. 460-465, 11 figs. Schemes of connections and diagrams of electromotive forces. From Elektrotechnische Zeitschrift, vol. 38, Sept. 20, 1917, p. 461.

Turbo-Alternators

Accidents to Steam Turbo-Alternators (Au sujet des accidents aux turbo-alternateurs à vapeur), P. Boucherot. Revue Générale de l'Electricité, vol. 4, no. 13, Sept. 28, 1918, pp. 457-460. Report of Sub-Committee of Union of Electrical Syndicates proposing as a result of studies (1) modifications in present designs of turbo-alternators, (2) modifications in usual specifications, and (3) dispositions to reduce loss when accident occurs.

The Production of Electricity by Steam Power, Alex. Dow. Elecn., vol. 81, no. 2111, Nov. 1, 1918, pp. 555-557. Abstract of address before Am. Electrochemical Soc.

GENERATORS AND MOTORS

Direct-Current Motors

Weight of Direct-Current Motors, A. Brunt. Elec. Eng., vol. 52, no. 2, Aug. 1918, pp. 28-29, 2 figs. Requirements of direct-current motors and graphs showing relation between weight and torque for commutating-pole and non-commutating-pole motors, and also between weight and torque for various makes of apparatus.

Induction Motors

Changing Speed of Induction Motors. Power Plant Eng., vol. 22, no. 22, Nov. 15, 1918, pp. 926-928, 2 figs. Possible speed changes of induction motors to suit conditions in power plants.

Rolling-Mill Motors

Standardizing Large Rolling Mill Motors, K. Pauly. Blast Furnace, vol. 6, no. 10, Oct. 1918, pp. 411-414, 1 fig. Suggests motors be rated on continuous capacity at some particular temperature in order to avoid present difficulties of users of large rolling-mill motors. Paper before Assn. Iron & Steel Elec. Engrs.

Single-Phase Generators

Armature Reaction and Wave Form of a Single-Phase Generator (in Japanese), G. Shimizu. Denki Gakkwai Zasshi, no. 362, Sept. 10, 1918.

Starting Resistances

Method for Determining Resistance Used for Starting Various Types of Motors, B. W. Jones. Power, vol. 48, no. 21, Nov. 19, 1918, pp. 740-741, 6 figs. A simple method for determining the ohmic value of resistance used for starting series-, shunt- and compound-wound direct-current motors and wound-rotor induction motors under various load conditions.

Synchronous Motors

For and Against Synchronous Motors, Will Brown. Elec. World, vol. 72, no. 21, Nov. 23, 1918, pp. 982-984, 4 figs. Four objections that have been frequently made to using synchronous motors; discussion showing how conditions have changed; synchronous motors and unity power factors.

Temperature Rise

Guarantees for Temperature Rise in Electrical Machinery, with Special Reference to Large Turbo-Generators, A. E. Du Pasquier. Tran. South African Inst. Elec. Engrs., vol. 9, part 7, July 1918, pp. 127-137 and (discussion) pp. 137-140. Urges that there is no good reason for restricting temperature rises, providing suitable materials are obtainable for withstanding the heat conditions that may arise.

See also MECHANICAL ENGINEERING, Fuels and Firing (Load Factor), Power Plants (Central Stations).

LIGHTING AND LAMP MANUFACTURE

Arc-Lamp Globes

Renovation of Discolored Arc-Lamp Globes, Alfred Herz. Elec. World, vol. 72, no. 20, Nov. 16, 1918, pp. 935-936, 2 figs. Description of a system of removing stain by heat treatment.

MEASUREMENTS AND TESTS

Galvanometers

The Einthoven Galvanometer, Samuel D. Cohen. Wireless World, vol. 6, no. 68, Nov. 1918, pp. 437-438. Special simple construction of Einthoven type used by writer for measuring radio receiving currents. From Elec. Experimenter.

Insulation Measurement

Electrolytic Method of Measuring Electrostatic Field of Insulators (La mesure du champ électrostatic dans les isolateurs, d'après la méthode électrolytique), W. Estorff. Revue Générale de l'Electricité, vol. 4, no. 12, Sept. 21, 1918, pp. 433-434, 1 fig. A small line is placed between electrodes in electrolyte and ratio of resistances of distances between line and each electrode is determined by Wheatstone bridge operating circuit with alternating current; correction coefficient for air values is determined in similar manner. From Elektrotechnische Zeitschrift, vol. 39, Feb. 7, 14 and 21, pp. 53, 62 and 76, 28 figs.

Some Notes on Leakage Indicators, G. W. Stubbings. Electricity, vol. 32, no. 1451, Aug. 30, 1918, pp. 453-454, 1 fig. Principle of instruments measuring state of insulation of a complete electrical system.

Meters

The Demand-Meter Situation, C. F. Mathes. Elec. World, vol. 72, no. 22, Nov. 30, 1918, pp. 1024-1026. Critical discussion of demand meters, pointing the advantages that are gained through use of well-known types of these instruments and remedies for some of the troubles encountered in their practical application.

Official Testing Laboratories

British Electrical Proving House. Times Eng. Supp., no. 527, Sept. 1918, p. 197. Essentials of schemed testing institution, with authoritative credentials, to deal with types of apparatus rather than with individual specimens.

Test-Ring Method

Test Ring Method for Determining Transformer Ratio and Phase Error, H. S. Baker. Elec. Rev., vol. 73, no. 20, Nov. 16, 1918, pp. 766-769, 6 figs. Use of special watt meter and current transformer for current transformer testing. From paper before Am. Inst. of Elec. Engrs.

POWER APPLICATIONS

Cement Industry

Electric Motors in the Cement Industry, R. B. Williamson. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 11, Nov. 1918, pp. 1237-1273, 9 figs. Outline of various kinds of machinery used, and data as to power requirements; description of types of motor best suited to each application together with starting characteristics, overload capacity, torque and other features. Also in Elec. Rev., vol. 73, nos. 20 and 21, Nov. 23 and 26, 1918, pp. 770-771 and 813-814.

Coal Mining

Explosionproof Equipments of Colliery Motors and Accessories (in Japanese). Denki Gakkwai Zasshi, no. 363, Oct. 10, 1918.

The Use of Electric Power in the Mining of Anthracite Coal, J. B. Crane. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 10, Oct. 1918, pp. 1197-1202, 7 figs. Power cost and current consumption of anthracite mines, also of bituminous mines; estimates of additional coal obtainable by electrification of anthracite mines, illustrations showing representative installations of electric drive.

Furnaces

Notes on Electric-Furnace Problems, J. L.

McK. Yardley. Bul. Am. Inst. Min. Engrs., no. 142, Oct. 1918, pp. 1593-1598, 4 figs. Analysis made to determine maximum capacity and aproximate performance of a new furnace designed to operate at 160 volts on a 60-cycle current.

Power Factor of the Electric-Arc Furnace (Fattore di potenza dei forni elettrici ad arco), O. Scarpa. Revista Tecnica d'Elettricita, no. 1891, Oct. 25, 1918, pp. 105-106. Presents formula for power factor of arc including power factor of furnace and ohmic resistance of electrodes.

Technical Analysis of Industrial Electric Furnaces: Classification, Choice of Apparatus, Installation and Operation (Considération techniques sur les fours électriques industriels; classification, choix des appareils, installation, mode d'emploi et conduite) Jean Escard. Revue Générale de l'Electricité, vol. 4, no. 16, Oct. 19, 1918, pp. 575-591, 31 figs. Electric arc furnaces; electric resistance furnaces; induction furnaces; electrothermotic and aluminum furnaces.

The Electric Furnace After the War, Francis A. J. Fitzgerald. Elec. Rev., vol. 73, no. 19, Nov. 9, 1918, pp. 726-727, 2 figs. Effect of the war upon electric furnaces; new uses to replace war's needs; tendencies in furnace design.

Heating

Electric Heat for Drying and Baking. George J. Kirkgasser. Indus. Management. vol. 56, no. 6, Dec. 1918, pp. 489-495, 11 figs. Types of industrial apparatus that have had rapid development during past five years.

Electric Thermal Storage Heaters for Rooms. English Mechanic & World of Sci., vol. 108, no. 2796, Oct. 25, 1918, pp. 155-156. Summary of report used by Committee of Swiss Electrotechnical Union. From Schweizerischer Elektrotechnischer Verein, Bul. June 1918.

Electrically Heated Industrial Appliances and Devices, George J. Kirkgasser. Indus. Management, vol. 56, no. 5, Nov. 1918, pp. 417-423, 32 figs. Outlines most important applications classified for 18 different industries, and shows many of simpler devices.

Iron-Ore Mining

Central Station Service Used in Operation of New Jersey Iron Ore Mines. L. R. W. Allison. Elec. Rec., vol. 24, no. 4, Oct. 1918, pp. 24-26, 5 figs. Installation where energy generated at steam station is transmitted to mines at 33,000 volts for operation of pumps, air compressors, hoists, etc., involving consumption of 600,000 kw-hr. per month.

Lime Plant

A Modern Motor-Driven Lime Plant. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, pp. 19-20, 4 figs. Processes in electrically-driven plant utilizing waste marble.

Pumping

Electricity Supersedes Steam in Los Angeles. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 18-19, 3 figs. Electrical operation of pumping plants, it is said, will effect an annual saving of 18,000 bbl. of fuel oil. Also in Elec. Rev., vol. 73, no. 19, Nov. 9, 1918, pp. 723-725, 3 figs.

High Efficiencies Shown by Motor-Driven Water Works Pumps, Geo. H. Gibson. Can. Engr., vol. 35, no. 19, Nov. 7, 1918, pp. 412-413, 2 figs. Data on two 12-in. centrifugal pumps.

Rolling Mills

Electrically Driven Mills at Bethlehem, J. T. Sturtevant. Blast Furnace, vol. 6, no. 10, Oct. 1918, pp. 417-419, 10 figs. Layout, equipment, power consumption and tonnage on eleven installations at Lehigh plant, where G. E. induction motors are used.

Ship Propulsion

Electricity's Part in Building and Navigating of Ships, H. A. Hornor. Elec. Eng., vol. 52, no. 2, Aug. 1918, pp. 15-22, 20 figs. Considerations entering into selection of propulsion: commercial angle, first cost, efficiency, safety, upkeep, cost of operation, etc.; propelling machinery of various ships. (Concluded.)

Silk Industry

Electric Drive Applied to Silk Industry, Charles T. Guilford. Elec. Rev., vol. 73, no. 22, Nov. 30, 1918, pp. 855-857, 4 figs. Advantages of central-station service for this work; selection of motors and drives; interesting data on present installations.

Sugar Mills

Complete Electrification of Sugar Mills, Clarence G. Hadley. Elec. World, vol. 72, no. 22, Nov. 30, 1918, pp. 1022-1024, 2 figs. Extensive application of motors in this industry of recent origin; satisfactory results obtained in new Cuban mills, showing possibilities that may arise in this field as it is developed.

See also CIVIL ENGINEERING, Earthwork, Rock Excavation, etc.; MECHANICAL ENGINEERING, Hoisting and Conveying (Electric Hoisting Machines), Welding (Electric Welding); METALLURGY, Alloys, Ferrous.

TELEGRAPHY AND TELEPHONY

Radio Telegraphy and Telephony

A Combination Circuit for Tube and Crystal. Wireless Age, vol. 6, no. 2, Nov. 1918, p. 21, 1 fig. Combined or individual use of vacuum tube and crystal rectifier.

A New Protective Condenser. Wireless Age, vol. 6, no. 2, Nov. 1918, p. 34, 1 fig. Designed to protect electrical transmission lines from effect of high-frequency disturbances.

A Novel Radio Telegraph Aerial. Wireless Age, vol. 6, no. 2, Nov. 1918, p. 20, 1 fig. Type having series of coils inserted in antenna from earth to free end.

A Thermionic Valve Slopemeter. E. V. Appleton. Wireless World, vol. 6, no. 68, Nov. 1918, pp. 458-460, 3 figs. Derives formula to compute slopes of grid voltage-anode current and plate voltage-anode current curves at any particular operating plant.

Marconi's Improved Radio Transmitter. Wireless Age, vol. 6, no. 2, Nov. 1918, pp. 19-20, 3 figs. Method of producing continuous oscillations by overlapping wave trains.

Method for Exhausting Vacuum Tubes. Wireless Age, vol. 6, no. 2, Nov. 1918, pp. 20-21, 1 fig. Apparatus which provides for heating anode by vigorous bombardment of electrons without endangering filament, this being method to drive gases from plate.

Propagation of Electric Currents in an Antenna (Propagation des courants électriques dans une antenne), H. Chireix. Revue Générale de l'Electricité, vol. 4, no. 11, Sept. 14, 1918, pp. 363-374, 9 figs. Formulae (1) in general case of non-homogenous antennae, (2) when antenna consists of one branch, (3) when it consists of two, and (4) when it consists of three branches having different self-inductances and different capacities.

Solid-Contact Detectors (Contribution à l'étude des détecteurs à contacts solides). René Audubert. Journal de Physique, vol. 7, May-June 1918, pp. 127-128. Study of physical phenomena which probably take place in the action of crystal detectors used in wireless telegraphy. (To be continued.)

Some Aspects of Radio Telephony in Japan, Eitaro Yokoyama. Wireless World, vol. 6, no. 68, Nov. 1918, pp. 430-435, 8 figs. Account of recent discoveries; evolution of a rarefied gas discharger. (To be continued.)

The Radioelectric Installation at Stavanger, Norway (Stavanger Radio), Olaf Moe. Teknisk Ukeblad, year 65, no. 43, Oct. 25, 1918, pp. 505-514, 23 figs. (To be continued.)

Telephony (Wire)

How to Locate Telephone Troubles. J. Bernard Hecht. Telephony, vol. 75, nos. 21, 22 and 23, Nov. 23, 30 and Dec. 7, 1918, pp. 32-34, 3 figs.; 13-16, 10 figs, and 16-18, 2 figs. Rural line telephones and their circuits. Suggestions to managers, wire chiefs and troublemen of local battery exchanges. (Continuation of serial.)

Wave-Length and Weakening of Telephone Circuits (Longueur d'onde et affaiblissement des circuits téléphoniques), Pomey. Revue Générale de l'Electricité, vol. 4, no. 8, Aug. 24, 1918, pp. 251-253. Simplification of author's formula for constant B given in Aug. 3 issue.

TRANSFORMERS, CONVERTERS, FREQUENCY CHANGERS

Transformers, A. C.

Study of the Calculations Involved in the Design of Large Capacity Transformers for Use with Electric Furnaces (Etude sur le calcul de transformateurs à forte intensité pour fours électriques). R. Jacquot. Revue Générale de l'Electricité, vol. 4, no. 15, Oct. 12, 1918, pp. 523-536, 9 figs. Explains sudden variations in efficiency and voltage drop by conditions of varying load and suggests practical and economical modifications. (To be continued.)

Rectifiers

Three-Phased Current Rectifier (Convertitore di correnti trifasi in correnti continue). O. M. Corbino. L'Elettrotecnica, vol. 5, no. 28, Oct. 5, 1918, pp. 392-394, 3 figs. Apparatus operating by rotary mercury jet.

Substations

Electric Railway Substations for Automatic Transformation (Sottostazioni di trasformazione automatiche per l'alimentazione de ferrovie elettriche). A. Gusmano. L'Elettrotecnica, vol. 5, no. 31, Nov. 5, 1918, pp. 444-446, 6 figs. Principles of system followed in America.

Permanence in Outdoor Substations, S. B. Hood. Elec. World, vol. 72, no. 20, Nov. 19, 1918, pp. 928-930, 6 figs. Discussion of standard design used in all sizes from 300 kva. to 2250 kva. in order to eliminate fire losses prevalent in modern structures; increase in cost to secure permanence held to be negligible.

Remote Controlled Substations Described, W. T. Snyder. Blast Furnace, vol. 6, no. 10, Oct. 1918, pp. 408-410, 2 figs. Control for central station and motor-generator substation located about 2200 ft. from main power station, feeding 250-volt direct-current transmission line. Paper before Assn. Iron & Steel Elec. Engrs.

Transformers, D. C.

Size and Working Cost of Machines for Continuous-Current Transformation, Thomas Carter. Elecn., vol. 81, no. 2108, Oct. 11, 1918, 4 figs. Methods of continuous-current transformation; differences between three schemes; conclusions in regard to cost and method of operation; curves of overall efficiency of transformer; schemes for variable-speed motors.

Frequency Changer

Radio Frequency Changers, E. E. Bucher. Wireless Age, vol. 6, no. 2, Nov. 1918, pp. 10-13, 8 figs. Reported progress in their application to wireless telegraphic and telephonic communication. (To be continued.)

TRANSMISSION, DISTRIBUTION, CONTROL

Distribution, Three-Phase

Economic Increase Made in Distribution Capacity, S. Bingham Hood. Elec. World, vol. 72, no. 22, Nov. 30, 1918, pp. 1030-1032, 7 figs. Saving of copper and transformers by replacing old overloaded 2300-volt system with 2300-2400-volt star-connected, three-phase, common-neutral primary and interconnected secondary.

How to Remedy Inconveniences of Excessive Overload in Three-Phase Network (Comment peut-on remédier aux inconvénients d'une très forte surcharge dans un réseau triphasé), E. Piernet. Revue Générale de l'Electricité, vol. 4, no. 15, Oct. 12, 1918, pp. 540-544, 2 figs. Proposes adjustment of step-up and step-down transformers so as to be able to dispose of voltage U so long as delivered power does not exceed a certain limit and of voltage $U\sqrt{3}$ when delivered power exceeds this limit.

Interconnection

More Light on New England Interconnection. Elec. World, vol. 72, no. 22, Nov. 30, 1918, pp. 1027-1029, 1 fig. Estimated savings to be exceeded; convenient energy-exchange arrangements; railroad electrification possible without buying new generators; price at which tie-line energy can be sold. From paper by L. L. Elden before Boston Section of Am. Inst. of Elec. Engrs.

Relays

Factors to Consider in Applying Relays, E. A. Hester. Elec. World, vol. 72, no. 20, Nov. 16, 1918, pp. 931-934, 9 figs. Determination of short-circuit current connections and settings suitable for radial and parallel feeder systems; protection against high-resistance grounds on balance systems.

Relay Protective Devices, C. J. Monk. Tran. South African Inst. Elec. Engrs., vol. 9, part 7, July 1918, pp. 140-143, 1 fig. Proposes short method of obtaining approximate circuit currents by observing voltage drop between two stations at normal load, according to equation: short-circuit current = normal voltage times load current divided by voltage drop. Discussion of paper published in Jl. of Inst., Oct. 1917.

Switches

An Automatic Three-Phase Switch, W. Ernst. Elecn., vol. 81, no. 2108, Oct. 11, 1918, pp. 491, 4 figs. Abstract of article in Elektrotechnische Zeitschrift, No. 4, 1918.

Safety Features in Switching Installations, M. M. Samuels and F. Bechoff. Elec. World, vol. 72, no. 19, Nov. 9, 1918, pp. 878-880, 9 figs. Review of existing alarm systems used to indicate switch positions and overheating of apparatus; weak points in installations and suggestions designed to bring about their improvement.

Transmission Lines

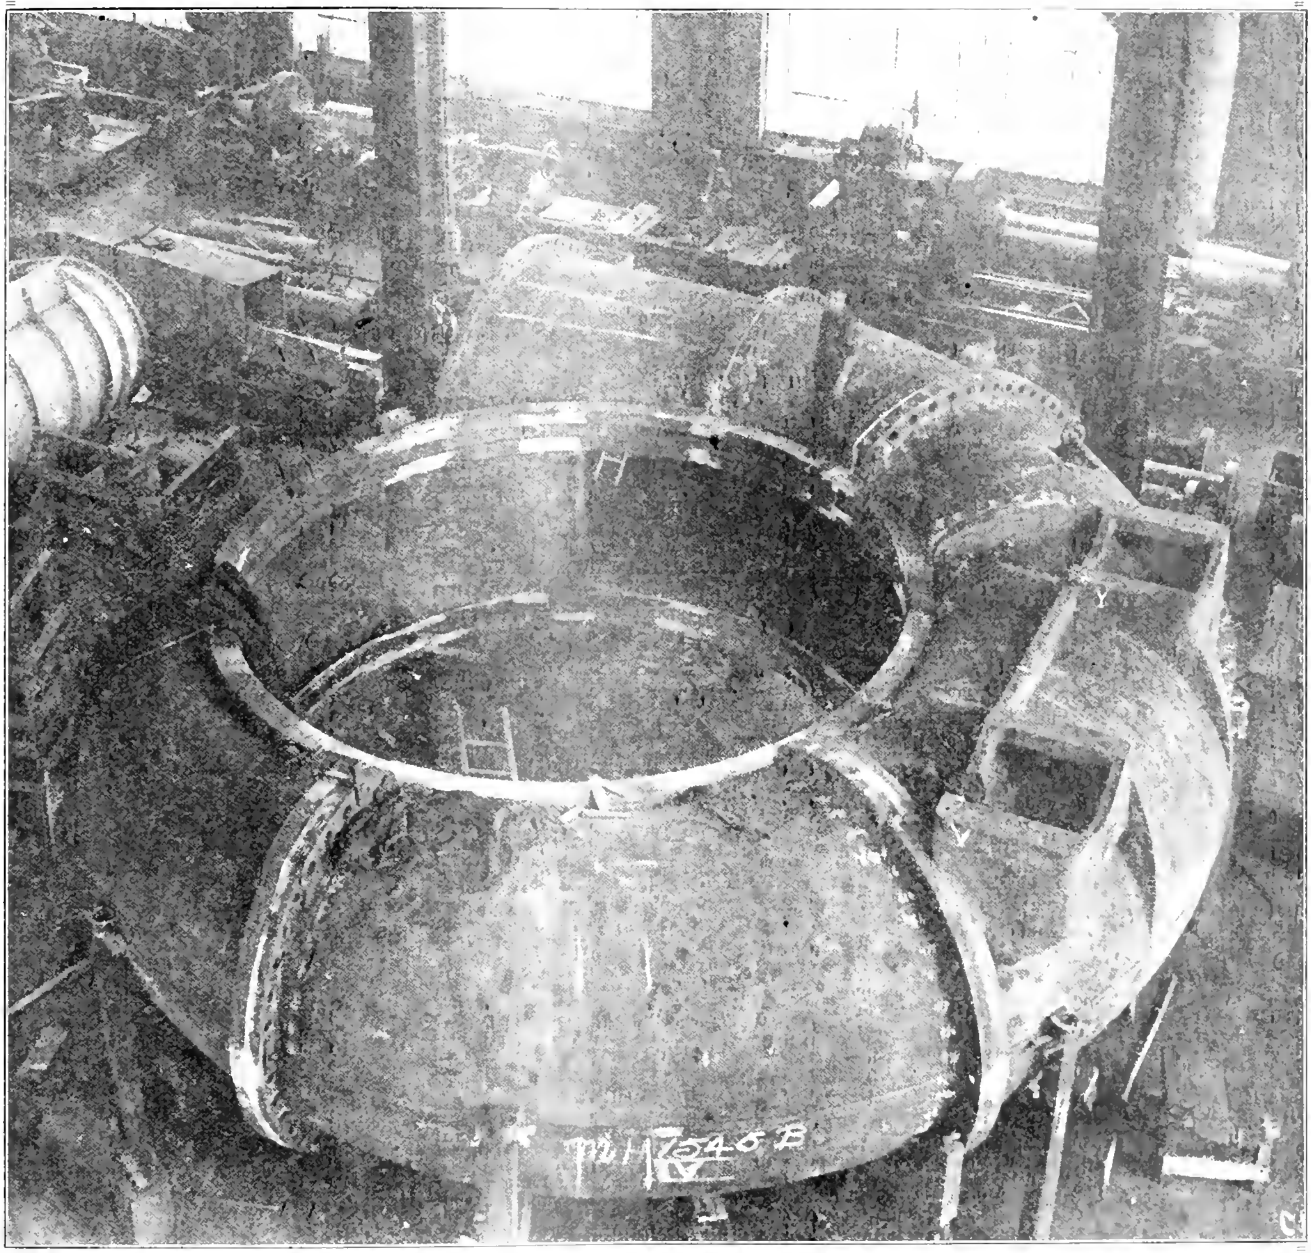
Locating Troubles in Electric Lines (Note sur les essais et mesures relatifs aux lignes électriques), Louis Puget. Revue Générale de l'Electricité, vol. 4, no. 16, Oct. 19, 1918, pp. 563-565, 2 figs. Method for measuring resistance of line and locating a ground, which author claims to have found serviceable in his experience with underground lines. The methods given are applicable to overhead lines as well.

110,000-Volt Transmission Line over the St. Lawrence River, S. Svenningson. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 11, Nov.

I. P. Morris Hydraulic Turbines

The Wm. Cramp & Sons Ship & Engine Building Co.

Richmond and Norris Sts., Philadelphia



THE MOST POWERFUL TURBINE EVER BUILT

Cast iron volute casing of **37,500 H. P.** Turbine for The Niagara Falls Power Company. The turbine is designed to develop the above power under a head of 214 feet, at a speed of 150 R. P. M. We have two of these units now under construction in our shops.

1918, pp. 1275-1284, 3 figs. Account of investigation leading to construction of 350-ft. towers to support transmission wires on a span of 4800 ft.; design of towers and insulators; provisions for protection from ice and method of sag calculations.

WIRING

House Wiring

Three- and Four-Way Switch Circuits, Terrell Croft. Elec. Eng., vol. 52, no. 2, Aug. 1918, pp. 23-25, 5 figs. Cottage wiring: unusual wiring; two-location control. (Concluded.)

Civil Engineering

BRIDGES

Concrete Bridges

Bridging the James River at Richmond, Va. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, pp. 15-16. General dimensions of structure consisting of 18 reinforced-concrete arch spans.

Reinforced Concrete Bridges and Their Architectural Treatment, F. G. Engholm. Contract Rec., vol. 32, no. 45, Nov. 6, 1918, pp. 880-883, 6 figs. Recommends considerations of fitness, proportion and adaptability in design, and moderate use of decorations.

Reinforced-Concrete Trestles. Sci. Am. Supp., vol. 86, no. 2238, Nov. 23, 1918, p. 324, 3 figs. Viaducts recently constructed by Can. Pac. Ry.

Design

New Impact Formulæ Needed in Designing Bridges of Various Types, J. A. L. Waddell. Eng. News-Rec., vol. 81, no. 21, Nov. 21, 1918, pp. 924-928, 2 figs. Scarcity of experimental knowledge of impact shown by review of tests and studies; group of formulæ proposed; lower impact allowances for solid-floor bridges and concrete arches.

The Principal Bridges of the World. Sci. Am. Supp., vol. 86, nos. 2235 and 2236, Nov. 2 and 9, 1918, pp. 286-288 and 294. Comparison of their size, importance and principles of design.

Highway Bridges

Standardization of Detail in Highway Bridge Design, M. W. Torkelson. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, pp. 33-34. Practice of Wisconsin Highway Commission.

Lift Bridges

Scherzer Lift-Bridge at Keadby (Ponte levatoio tipo Scherzer a Keadby). Ingegneria Italiana, vol. 2, no. 37, Sept. 5, 1918, pp. 131-134, 7 figs. Plans, dimensions and details of mechanism. From Génie Civil, Jan. 19, 1918.

Railroad Bridges

Special Foundation Work for a Railroad Bridge, J. H. Merriam. Ry. Age, vol. 65, no. 22, Nov. 29, 1918, pp. 951-953, 6 figs. New Burlington structure over Platte River is supported entirely on concrete piles.

Wilson Bridge

The Wilson Bridge at Lyons. Engineer, vol. 126, no. 3280, Nov. 8, 1918, pp. 387-388, 9 figs. Drawings, illustrations and description of le pont Wilson, formally opened at Lyons July 14, 1918, and named in honor of President Wilson.

BUILDING AND CONSTRUCTION

Churches

Steel Construction Characterizes Chicago Church. Eng. News-Rec., vol. 81, no. 19, Nov. 7, 1918, pp. 860-863, 5 figs. Cantilever trusses carry front wall and gallery; dome trusses are supported by girders on tall four-post tower having no interior bracing.

Concrete Pedestal Pile

The McArthur Concrete Pedestal Pile. Contract Rec., vol. 32, no. 42, Oct. 16, 1918, pp. 830-831, 2 figs. Process followed in construction of pile consisting of a 16-in. cylindrical shaft, with an enlarged base.

Fire-Resistive Construction

Fire Resistive Construction Committee Report. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 13-14, 1 fig. Specifications drawn by joint conference of representatives from ten American technical societies and the Can. Soc. of Civil Engrs.

Railroad Station

Toronto's Union Station Nears Completion. Contract Rec., vol. 32, no. 41, Oct. 9, 1918, pp. 805-808, 9 figs. Waterproofing; roof; elevators.

Reservoirs, Oil

Circular Earth Embankment Lined with Concrete Forms Oil Reservoir, E. D. Cole. Eng. News-Rec., vol. 81, no. 21, Nov. 21, 1918, pp. 932-936, 3 figs. Type originated in California; introduced into Texas fields on account of lack of steel; concrete roof carried on wood frame also because of lack of steel.

Reinforced Concrete Fuel-Oil Tanks. Can. Engr., vol. 35, no. 17, Oct. 24, 1918, p. 376, 2 figs. Dimensions and process of executing work.

Reservoirs, Water

Newton, Mass., Water Reservoir, Edwin H. Rogers, Eng. Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 9-12, 3 figs. Details of its four rectangular sections and circular gate chamber at center, in which are installed a steel distributing tank and pipes from force main to different sections and overflow pipes and drains. From Proc. Boston Soc. Civil Engrs.

Reinforced Concrete Reservoirs, Montevideo. Engineering, vol. 106, no. 2756, Oct. 25, 1918, pp. 453-455, 43 figs. Description of two 6,500,000-gal. reservoirs constructed for City of Montevideo, Uruguay, R. C. Parsons, Engineer. Drawings of principal features.

Scaffolds and Falsework

Safe Construction of Scaffolds and Falsework, T. F. Foltz. Contract Rec., vol. 32, no. 42, Oct. 16, 1918, pp. 826-829. Outlines general construction of pole, suspended, outrigger, carpenters' bracket and painters' scaffolds, and indicates their general construction requirements. Paper before Nat. Safety Council.

Submerged Structures

Essentials of Proper Construction, J. W. Rollins. Contract Rec., vol. 32, no. 44, Oct. 30, 1918, pp. 870-873. Requirements of concrete for submerged structures.

See also ORGANIZATION AND MANAGEMENT, Lighting.

CEMENT AND CONCRETE

Agregate

Clean Aggregates Obtained under Difficult Conditions, C. P. Mowry. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, pp. 31-32, 3 figs. Arrangement and working of a western plant.

Proportioning the Materials of Mortars and Concretes by Surface Areas of Aggregates, L. N. Edwards. Surveyor, vol. 54, no. 1398, Nov. 1, 1918, pp. 209-210. Results of tests made by Toronto Department of Works with object of developing surface-area method of proportioning and securing information relative to (1) surface area of aggregates of varying granulometric composition, (2) quantity of water necessary to produce a "normal" uniform consistency of mortar for varying sands and cement constant, and (3) strength of mortar attained by varying proportion of cement in mix. Paper before Am. Soc. for Testing Materials.

Economical Production of Washed Sand and Gravel. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 52-54, 2 figs. Description of Gilbert screen.

Cement Gun

Cement Gun Used for Repairing Pit Stacks. Blast Furnace, vol. 6, no. 10, Oct. 1918, pp. 399-401, 5 figs. Steel reinforcement placed on old shell and gunite applied.

Cold-Weather Concreting

Cold Weather Concreting. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 20-24, 8 figs. Effect of low temperatures on concrete work; suggestions of Portland Cement Assn. in regard to heating materials and protecting work.

Disintegration

Conclusions on Causes of Concrete Disintegration, A. Blackie. Eng. & Contracting, vol. 50, no. 21, Nov. 20, 1918, pp. 503-505. From paper before Eng. Ins. of Canada.

Form Units

One Set of Tool Forms Used Three Times Completes Concrete Foundry, J. M. Villadsen. Eng. News-Rec., vol. 81, no. 21, Nov. 21, 1918, pp. 950-951, 3 figs. Form units assembled on ground with reinforcement in place erected by derrick; concrete placed by telescoping chute.

François and Portier Cementation Processes

Cementation Processes of François and Portier, A. H. Krynauw. Contract Rec., vol. 52, no. 44, Oct. 30, 1918, pp. 864-865. Conditions most suitable for hard setting in shortest time when cement is pumped under pressure into fissures; cases in which cementation has been successfully applied; comparison between two processes. Paper before Chem. Metallurgical & Min. Soc.

Moisture

Effect of Water on Strength of Concrete. Contract Rec., vol. 52, no. 44, Oct. 30, 1918, p. 865, 1 fig. Diagram presenting amount of water used in per cent of quantity giving maximum strength against per cent of maximum strength. Drawn from results of experimental tests.

Saturation of Concrete Reduces Strength and Elasticity, M. B. Lagaard. Eng. News-Rec., vol. 81, no. 20, Nov. 14, 1918, pp. 908-910, 6 figs. Tests, made at University of Minnesota, show that moisture content of specimens serves to counteract benefits of moist curing.

See also CIVIL ENGINEERING, Building and Construction, Harbors.

EARTHWORK, ROCK, EXCAVATION, ETC.

Blasting

Drilling and Blasting in Construction of Halifax Ocean Terminals Railway. Eng. & Contracting, vol. 50, no. 21, Nov. 20, 1918, pp. 480-481. Description of some features of work. From paper by B. H. Smith before Eng. Inst. of Canada.

Quarry Blasting with Electricity, A. S. Anderson. Du Pont Magazine, vol. 9, no. 6, Dec. 1918, pp. 26-27, 3 figs. Ways of producing current and precaution to be observed.

Park Construction

Construction Plans Developed for the Bronx River Parkway Reservation, L. G. Holleran. Eng. News-Rec., vol. 81, no. 20, Nov. 14, 1918, pp. 899-903, 4 figs. Designs of Park Commission contemplate development of 1400 acres by grading and planting; numerous structures proposed; work to be done by day labor.

Quarrying

Quarry Economics, Oliver Bowles. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 49-50. Labor requirements of various drills; waste of labor through inefficient blasting; effect of physical character of rock.

HARBORS

Concrete Construction

The Use of Reinforced Concrete Construction in Harbor Work, A. F. Dyer. Jl. Eng. Inst. Can., vol. 1, no. 6, Oct. 1918, pp. 242-251, 11 figs. Descriptions derived from articles and papers published in technical journals and proceedings of technical societies. Also in Eng. & Contracting, vol. 50, no. 21, Nov. 20, 1918, pp. 483-485.

Piers

Compression Strengths of Large Brick Piers. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, p. 25. Summary of conclusions based on past records and recent investigation by Bureau of Standards, composed of tests on piers 2 ft. 6 in. sq. by 10 ft. high in which three grades of brick were used.

Ports

Railway Construction in Connection with the Halifax Ocean Terminals, R. H. Smith. Jl. Eng. Inst. Can., vol. 1, no. 6, Oct. 1918, pp. 281-288. Methods employed and difficulties overcome in construction operations which necessitated considerable excavation work and presented other difficulties.

St. John Harbor, Alex. Gray. Jl. Eng. Inst. Can., vol. 1, no. 6, Oct. 1918, pp. 273-278, 15 figs. Outstanding features in harbor and type of construction used in wharves.

The Port of Honduras. Times Eng. Supp., no. 527, Sept. 1918, p. 193. Projected improvements.

Sea Walls

Drive Inclined Precast Concrete Slabs for Sea Wall. Eng. News-Rec., vol. 81, no. 20, Nov. 14, 1918, pp. 897-898, 3 figs. Account of new type of beach protection replacing vertical concrete wall at Long Beach, Cal.

Pneumatic Caisson Method of Quay Wall Construction at Halifax. Eng. & Contracting, vol. 50, no. 21, Nov. 20, 1918, pp. 489-490, 2 figs. From paper by J. J. MacDonald before Eng. Inst. of Canada.

MATERIALS OF CONSTRUCTION

Timber

Decay in Mill-Roof Timber, R. J. Blair. Textile World Jl., vol. 54, no. 23, Dec. 7,

CRANE VALVES

MUNICIPAL ENGINEERING

Town Planning

The Problem of City Development, An Economic Survey, A. G. Dalzell. Jl. Eng. Inst. Can., vol. 1, no. 7, Nov. 1918, pp. 319-330, 16 figs. Comparison of rectangular and diagonal systems of city outline and study of conditions in Vancouver.

Town Planning in Halifax and Vicinity, H. L. Seymour. Jl. Eng. Inst. Can., vol. 1, no. 6, Oct. 1918, pp. 262-268, 3 figs. Schemes indicating width of streets, open spaces, building lines and character of buildings.

ROADS AND PAVEMENTS

Canada

Canadian Highway Construction, Harry Stewardson. Contract Rec., vol. 32, no. 46, Nov. 13, 1918, pp. 899-901. Considers how to distribute cost of construction and maintenance so that necessary money can be secured and necessary expense fairly placed upon people who use roads and communities which receive benefits.

Highway Work in Ontario. Good Roads, vol. 16, no. 20, Nov. 16, 1918, pp. 185-186 and 191. Progress made in Canadian Province.

Roadway Improvements in Ontario, W. A. MacLean. Contract Rec., vol. 32, no. 41, Oct. 9, 1918, pp. 813-819, 10 figs. Extracts from annual report of Department of Public Highways for 1917.

Concrete

Concrete Road Construction, William W. Cox. Good Roads, vol. 16, no. 18, Nov. 2, 1918, pp. 165-166 and 169, 1 fig. Precautions and care to be observed. Paper before Mich. State Good Roads Assn.

Vertical Movements in Concrete Pavements and a Suggestion Towards Their Elimination, J. W. Lowell. Eng. & Contracting, vol. 50, no. 19, Nov. 6, 1918, pp. 441-443, 4 figs. From paper before Am. Concrete Inst.

Cost Keeping

Better System of Highway Cost Keeping, J. J. Tobin and A. R. Losh. Contract Rec., vol. 32, nos. 44, 45 and 46, Oct. 30 and Nov. 6 and 13, 1918, pp. 866-869, 886-888 and 903-906, 4 figs. Study of principles governing cost keeping and application of these principles to highway work. Detail of cost accounts and necessary codes.

France

Principles Upon Which the French Highways Are Built, Frank W. Harris. Eng. News-Rec., vol. 81, no. 21, Nov. 21, 1918, pp. 935, 1 fig. Roman system of direct lines between strategic points followed; great attention is given to drainage.

Location

Putting the Right Road in the Right Place, Rodman Wiley. Am. City, vol. 19, no. 5, Nov. 1918, pp. 356-358, 4 figs. European practice in locating road; importance of exercising good judgment in grading and surfacing. Paper before Ky. Highway Engrs. Assn.

Macadam

Capacity of Macadam Roads for War Business Increased. Eng. News-Rec., vol. 81, no. 22, Nov. 28, 1918, pp. 990-992, 5 figs. Three-foot concrete shoulders added at each side without closing highways to traffic; war labor conserved by using convicts for construction.

Oiled Macadam Roads Resurfaced with Concrete, E. A. Burt. Eng. News-Rec., vol. 81, no 21, Nov. 21, 1918, pp. 943-944, 3 figs. Los Angeles County, California, builds roads in two sections to keep traffic moving; center joint keeps autos on own side; cost figures.

Tar-Macadam v. Granite Macadam, Ellis W. Jones. Surveyor, vol. 54, no. 1399, Nov. 8, 1918, p. 220. Author's experience and recommendation that roads which have to carry from 600 to 1,000 tons a day should be maintained with tar-macadam.

Maintenance

Motor Vehicles and Their Influence Upon Road Construction, W. A. Maclean. Surveyor, vol. 54, no 1399, Nov. 8, 1918, pp. 221-222. Record of Deputy Minister of Public Highways for Ontario.

Road Maintenance Methods and Devices Effect Saving of Material, Labor and Fuel. Eng. News-Rec., vol. 81, no. 22, Nov. 28, 1918, pp. 981-984, 5 figs. Bureau of Maintenance and Repair, New York State Highways Department, working through nine division engineers, endeavors to keep war-time traffic roads open and still conserve material.

Mixers

Direct Charging of Concrete Mixers. Mun. Jl., vol. 45, no. 20, Nov. 16, 1918, p. 392. Feature of construction of concrete pavement in ten-mile section of Delaware road.

Two Mixers on Variable Road Work. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 31-32, 2 figs. Methods followed in construction of a Western road.

Snow Removal

Snow Removal on Trunk Line Highways, Chas. J. Bennett. Good Roads, vol. 16, no. 20, Nov. 16, 1918, pp. 188-189. Study of the problem and suggestion for its solution. Before conference On Snow Removal from Trunk Highways, Automobile Club of America.

Surfacing

How to Get the Best Surface on a Concrete Road, A. H. Hunter. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, pp. 25-28, 2 figs. Suggestions in regard to application of forms, building of expansion joints and use of roller and belt.

Resurfacing Part of Buffalo-Albany Turnpike with Concrete, A. S. Hinman. Cement & Eng. News, vol. 30, no. 11, Nov. 1918, pp. 35-36, 3 figs. Method of carrying on work without closing traffic.

Wood Roads

Gasoline Consumption Tests Demonstrate Value of Hard, Smooth-Surfaced Roads, A. N. Johnson. Eng. News-Rec., vol. 81, no. 19, Nov. 7, 1918, pp. 843-850, 8 figs. Gasoline saving which would pay for construction of hard surface in few years is indicated between earth and smooth concrete, where daily motor traffic of 500 can be expected. Results of some tests and description of methods employed.

Paved Roadways Aid Plant Efficiency, H. Colin Campbell. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 471-472, 4 figs. Plea for better roadways around factory buildings.

The Measure of a Good Road, Robert C. Barnett. Eng. & Contracting, vol. 50, no. 19, Nov. 6, 1918, pp. 438-440, 3 figs. Mathematical treatment of thesis. Assumptions of good road: 1. A straight line is shortest distance between two points; 2. A plane of uniform slope is best grade between two points; 3. A hard, smooth surface offers less tractive resistance than rough or yielding one.

The Vital Importance of the Highway, S. M. Williams. Am. City, vol. 19, no. 5, Nov. 1918, pp. 354-355, 1 fig. Plea for establishment of Federal Highway Commission.

See also MECHANICAL ENGINEERING, Machinery, Special (Road Finisher)

SEWAGE DISPOSAL

Dilution

Sewage Disposal by Dilution. Times Eng. Supp., no. 527, Sept. 1918, p. 188. Experimental investigation of Royal Commission on Sewage Disposal into self-purifying capacity of rivers.

Direct Oxidation

Sewage Treatment in Easton. Mun. Jl., vol. 45, no. 20, Nov. 16, 1918, pp. 386-388, 4 figs. Details and method of operation of plant of 1,000,000 gal. capacity of "direct oxidation" type.

Sewer Pipe

Incrustation in Vancouver Sewer Pipe, A. G. Dalzell. Can. Engr., vol. 35, no. 19, Nov. 7, 1918, pp. 403-406, 3 figs. Objectionable features which have developed in machine-made concrete pipe, 8 to 30 in. in diameter.

Sludge Dewatering

Two Important Sludge Problems, Arthur J. Martin. Contract Rec., vol. 32, no. 48, Nov. 27, 1918, pp. 941-942. Suggestions in regard to use of compressed air and removal of water contained in sludge.

WATER SUPPLY

Consumption

Water Consumption in New York State Cities and Its Effect on Coal Consumption. Am. City, vol. 19, no. 5, Nov. 1918, pp. 376-378. From a report compiled by the State Bureau of Municipal Information of the New York State Conference of Mayors.

Mains in Winter

Waterworks Operation. Mun. Jl., vol. 45, no. 21, Nov. 23, 1918, pp. 408-410. Methods of thawing water mains and services.

Pollution

Sanitary Aspects of Water Supplies at Army Cantonments, James T. B. Bowles. Eng. & Contracting, vol. 50, no. 20, Nov. 13, 1918, p. 460. From Sept. Jl. of Am. Waterworks Assn.

Railway Water Supply

New Water Treating Plants for the Burlington. Ry. Rev., vol. 63, no. 19, Nov. 9, 1918, pp. 661-666, 10 figs. Use of reinforced-concrete tanks on Casper division; various conditions of water supply; different types of construction.

Railway Water Supply from Wells. Ry. Rev., vol. 63, no. 19, Nov. 9, 1918, pp. 669-671. From report of committee on sources of railway water supply, to Am. Ry. Bridge and Building Assn., Chicago, Oct. 15, 1918, by C. R. Knowles, chairman.

Sand Filters

Coagulants Versus Sand Filters as Aid to Water Purification in the Field, H. S. Briggs and E. R. Marie. Contract Rec., vol. 32, no. 46, Nov. 13, 1918, pp. 906-908. Description of installation embodying alum process. From Roy. Engrs. Jl.

Drifting Sand Filter, Toronto Island, Geo. G. Nasmith and N. J. Howard. Can. Engr., vol. 35, no. 17, Oct. 24, 1918, pp. 359-364, 6 figs. Report of bacteriological and physical tests performed on section comprising five filter units.

Toronto's Drifting Sand Filter. Mun. Jl., vol. 45, no. 20, Nov. 16, 1918, pp. 390-392. Construction and operation; bacteriological and physical tests; conclusions as to efficiency of plant.

WATERWAYS

Dams

High-Pressure Gates in Dams for Water-Works and Irrigation Reviewed, D. W. Cole. Eng. News-Rec., vol. 81, no. 20, Nov. 14, 1918, pp. 880-884, 5 figs. From sluice gates in Sudbury Dam of Boston Water-Works through various stages of gate development in high dams of U. S. Reclamation Service. From paper presented at Idaho conference of engineers in 1918.

Modifications in the Character of a Water Stream Produced by Construction of a Dam (Modifications apportées au régime d'un cours après l'établissement d'un barrage), K. Zorayan. Revue Génerale de l'Electricité, vol. 4, no. 7, Aug. 17, 1918, pp. 226-229, 5 figs. Chart for tracing output curve knowing the declivity of a water course and the height of water in dam.

Gates

Some Experiences with Large-Capacity Reservoir Outlets, James M. Gaylord. Eng. News-Rec., vol. 81, no. 21, Nov. 21, 1918, pp. 945-950, 2 figs. Specially designed gates control discharge of immense volumes of water under pressures above 200 ft.; difficulties and how they have been overcome. Paper before Colorado Assn. of members of Am. Soc. of Civil Engrs.

Run-Off

Progress Report of Committee on Run-Off. Jl. Boston Soc. Civil Engrs., vol. 5, no. 9, Nov. 1918, pp. 387-422, 3 figs. Use of the current meter in stream gaging; 0.2 and 0.8 method in power canals; precipitation, evaporation and run-off; effects of ice on river discharge; methods to be used in compilation of data.

Stream Regulation

Stream Regulations in Quebec Province, Olivier Lefebre. Can. Engr., vol. 35, no. 19, Nov. 7, 1918, pp. 399-402 and 411, 5 figs. Account of increase in water power by using Lakes St. Francis and Aylmer as storage basins and indications of possible developments. From Annual Report of Quebec Streams Commission.

See also MECHANICAL ENGINEERING, Hydraulic Machinery.

Mining Engineering

ALLOYS, FERROUS

Electric Furnace

Two-Ton Electric Furnace Makes Alloys. Can. Machy., vol. 20, no. 20, Nov. 14, 1918, pp. 563-565, 10 figs. Equipment of plant using Héroult furnaces for non-ferrous alloys.

BASE MATERIALS

Serpentine

The Origin of Serpentine, a Historical and Comparative Study, W. N. Benson. Am. Jl. of Sci., vol. 46, Dec. 1918, pp. 693-731, 4 figs. Concludes from examination of geological data that ultrabasic masses in chrysolite or antigorite-serpentine are alteration product of originally intrusive peridotite often more or less pyroxenic, and that in some cases the hydration was brought about by agency of waters emanating from same magma that produced periodite, the change having been completed by end of one orogenic period of vulcanicity.

COAL AND COKE

Anthracite

Anthracite Production and Resources of the United States, Eli T. Connor. Can. Min. Inst., bul. no. 80, Dec. 1918, pp. 1001-1005. Map. Excerpts from address at 20th annual meeting of the Institute. Progress of the anthracite industry since 1895.

Breakers and Washeries

Hazards and Safeguards in Anthracite Breakers and Washeries, D. K. Glover. Safety Eng., vol. 36, no. 4, Oct. 1918, pp. 234-236. Recommends clearance of 7 ft. from center of track on each side. From Proc. Seventh Annual Safety Congress.

Coke Ovens

Economic Considerations in Coke-Oven Practice, W. Colquhoun. Ir. & Cl Trds. Rev., vol. 97, no. 2646, Nov. 15, 1918, pp. 541-543. Advantages of by-product coke-ovens. Abstract of paper and discussion read before Midland Inst. of Min., Civ. & Mech. Engrs.

Instantaneous Combustion

Instantaneous Combustion of Coal and Gas at Bedford Collieries, Leigh, F. N. Siddall. Trans. Manchester Geol. & Min. Soc., vol. 35, part 10, Aug. 1918, pp. 318-325, 3 figs., and (discussion) pp. 325-327. Account of conditions in shaft before and after occurrence of an outburst.

Kentucky

The Hazard Coal Field, P. M. Sherwin. Coal Age, vol. 14, no. 23, Dec. 5, 1918, pp. 1031-1034, 11 figs. Known chiefly for its hardness and low ash content. Describes region.

Shoveling Machines

Shoveling Machines for Coal Mines. Coal Industry, vol. 1, no. 10, Oct. 1918, pp. 382-384, 4 figs. Development of mines; method of operating shoveling machines; tests under different conditions.

See also ELECTRICAL ENGINEERING, Power Applications (Coal Mining).

EXPLOSIVES

Permissible Explosives for Mine Use, J. H. Squires. Coal Industry, vol. 1, no. 10, Oct. 1918, pp. 375-379, 9 figs. Definition of permissible explosives and description of tests and appliances necessary to determine classification.

IRON

Alsace-Lorraine

Iron Ore Supplies of Alsace-Lorraine, Sidney Paige. Iron Age, vol. 102, no. 19, Nov. 7, 1918, pp. 1149-1150. From symposium on "Certain Ore Resources of the World" prepared for meeting of Iron and Steel section, Am. Inst. of Min. Engrs., Milwaukee, October 1918.

Briquetting

Present Knowledge and Practice in Briquetting Iron Ores (V), Guy Barrett and T. B. Rogerson. Automotive Eng., vol. 3, no. 9, Oct. 1918, p. 425. The Greenwalt, West and other general processes; general observations on briquetting, its applications, cost under various processes, disadvantages and possibilities. (Concluded.)

See also ELECTRICAL ENGINEERING, Power Applications (Iron-Ore Mining).

LEAD

Flotation

The Development of Galena Flotation at the Central Mine, Broken Hill, R. J. Harvey. Instn. Min. & Met., bul. 170, Nov. 14, 1918, pp. 1-17, 7 figs. Experimental work and results.

MAJOR INDUSTRIAL MATERIALS

Manganese

Manganese Deposits in the Colorado River Region. Salt Lake Min. Rev., vol. 20, no. 15, Nov. 15, 1918, p. 30. Replacement deposits; methods and cost of mining. (Concluded.)

Sulphur

Sulphur Deposits of the Trans Pecos Region in Texas, Kirby Thomas. Eng. & Min. Jl., vol. 106, no. 23, Dec. 7, 1918, pp. 979-981, 3 figs. Origin, character of deposits, methods of mining, etc.

MINES AND MINING

Bounces

An Unusual Bounce Condition, A. C. Watts. Coal Age, vol. 14, no. 23, Dec. 5, 1918, pp. 1028-1030, 4 figs. Bounces occurred with annoying frequency. A fault was driven through and analysis made of existing conditions.

Cementing of Wells

Cement Plugging for Exclusion of Bottom Water in the Augusta Field, Kansas. Bul. Am. Inst. Min. Engrs., no. 142, Oct. 1918, pp. 1613-1620, 6 figs. Results obtained from preliminary cementing of wells in effort to cut off bottom water.

Field Tests

Field Tests for the Common Metals in Minerals. Univ. Ariz., bul. no. 93, Min. Tech. Series, no. 21, pp. 1-20. Compiled to be used as a text for lectures on "Prospector's Mineralogy."

Gas Detector

Improved Mine-Gas Detector. Min. & Eng. Rec., vol. 23, nos. 17 & 18, Sept. 30, 1918, pp. 180-181, 1 fig. Apparatus, developed by Bureau of Mines, for determining presence of inflammable gases and proportion of gas present.

Mine Timbers

Preservative Treatment of Mine Timbers as a Conservation Measure, Kurt C. Barth. Cl. Age, vol. 14, no. 23, Dec. 5, 1918, pp. 1025-1027. Three methods of application available.

Minerals Control Act

Will the Government Fulfill Its Obligations to Those Who Undertook Mineral Developments at Its Request? Mfrs. Rec., vol. 74, no. 23, Dec. 5, 1918, pp. 73-74. Discusses the Minerals Control Act and necessary protection to make the United States more self-sustained as a nation.

Rescue Apparatus

New Form of Oxygen Mine Rescue Apparatus, H. V. Manning. Min. & Eng. Rec., vol. 23, nos. 17 & 18, Sept. 30, 1918, pp. 179-180, 2 figs. Apparatus, developed by Bureau of Mines, for use poisonous or irrespirable atmospheres in mines after fires or explosions.

Stone-Dust Removal

Sprayer for Stone-Dusting in Mines, A. Rushton. Tran. Manchester Geol. & Min. Soc., vol. 35, part 10, Aug. 1918, pp. 327-329. Features of ejector which blows stone dust into atmosphere of mine by means of compressed air. Stone dust is carried from atmosphere of mine in the same way as coal dust.

Temperature Measurements

Measurement of Temperature at Great Depths (Mesure de la temperature dans les sondages à toute profondeur), M. Verzat. L'Echo des Mines et de la Métallurgie, no. 2582, July 14, 1918, p. 343. Account of the measurement of temperature at a depth of 1616 meters made by the Cie. des Mines du Sud de la Mure.

Timbering

Safe and Efficient Mine Timbering, Robert Z. Virgin. Coal Industry, vol. 1, no. 10, Oct. 1918, pp. 369-372, 12 figs. Explains and illustrates different methods and analyzes each with regard to safety and efficiency.

Transfer Chutes

Driving and Timbering Transfer Chutes, C. T. Rice. Eng. & Min. Jl., vol. 106, no. 23, Dec. 7, 1918, pp. 991-993, 3 figs. Method employed in the Coeur d'Alene district.

See also MECHANICAL ENGINEERING, Hoisting and Conveying.

MINOR INDUSTRIAL MATERIALS

Antimony, Strontium, etc.

Antimony, Graphite, Nickel, Potash, Strontium, Tin, E. S. Boalich and W. O. Castello. Cal. State Min. Bur., report no. 5, Mar. 1918, 44 pp. Properties, occurrence and uses of these substances.

Tungsten

Tungsten, Molybdenum and Vanadium, E. S. Boalich and W. O. Castello. Cal. State Min. Bur., report no. 4, Mar. 1918, 34 pp. Properties, ores, occurrence and uses of these minerals.

Wolfram Ore and Tungsten. Chem. News, vol. 117, no. 3059, Oct. 25, 1918, pp. 337-338. Report of Departmental Committee on the Eng. Trades after the War. From Jl. Roy. Soc. of Arts, vol. 66, no. 3436.

OIL

Water Troubles

Water Troubles in the Mid-Continent Oil Fields and Their Remedies, Dorsey Hager and G. W. McPherson. Bul. Am. Inst. Min. Engrs., no. 142, Oct. 1918, pp. 1620-1627, 2 figs. Classification of troubles and account of results obtained by shutting off water.

PRECIOUS MINERALS

Kalgoorlie

Kalgoorlie Goldfield. Aust. Min. Std., vol. 60, no. 1564, Oct. 31, 1918, pp. 705 and 707. Report of J. B. Jaquet on circumstances connected with certain earth tremors, presence of methane gas, systems of working, etc.

RARE MINERALS

Wilsonium

Wilsonium, Henri Bonaparte. Min. & Eng. Rec., vol. 23, nos. 17 and 18, Sept. 30, 1918, pp. 176-177. Chemical and physical nature and occurrence of new mineral named in honor of President Wilson by its discoverer, Franklin Heath.

TIN

Metallurgy

Effect of Heating and Heating and Quenching Cornish Tin Ores Before Crushing, Arthur Yates. Instn. Min. & Metallurgy, bul. 170, Nov. 14, 1918, pp. 1-3. Summary of investigation made in the laboratories of the Royal School of Mines.

Ore Handling

Installation for Mechanical Handling of Tin Ore at Boeboes Valley on the Banka (Installaties voor machinale ontginning van tinerts in de Boeboes-vallei op Banka), A. Van der Ham. De Ingenieur, vol. 33, no. 41, Oct. 12, 1918, pp. 789-802, 19 figs.

Tin Conservation

A Symposium on the Conservation of Tin. A.I.M.E. bul. no. 144, Dec. 1918, pp. 1729-1764. Eight short papers.

Conserving Tin in Different Solder Mixtures, Milton L. Lissberger. Foundry, vol. 46, no. 316, Dec. 1918, pp. 579-580. Experiments indicate that the ideal alloy should contain 46 per cent tin and 54 per cent lead; preventing tin waste. From paper before Milwaukee meeting of Inst. of Metals Division of Am. Inst. of Min. Engrs.

TRANSPORTATION

Dump Cars

Dumps and Dump Hoppers, C. L. Miller. Coal Industry, vol. 1, no. 10, Oct. 1918, pp. 373-374, 2 figs. Suggestions for making layouts addressed to mining engineers having no other data at hand than details of mine car.

Metallurgy

ALUMINUM

Aluminum and Its Alloys, Dr. Rosenhain. Aeronautics, vol. 15, no. 259, Oct. 2, 1918, pp. 321-322. Uses and possibilities in aircraft. Lecture at British Sci. Products Exhibition.

Aluminum and Its Light Alloys—VI. Bibliography, Paul D. Merian. Chem. & Metallurgical Eng., vol. 19, No. 10, Nov. 15, 1918, pp. 729-732. Composition; applications; electrical; vessels; deoxidation; aluminothermy; chemical properties; corrosion; alternbility; physical properties; electrical conductivity; thermoelectromotive force characteristics; conductivity; effect of temperature on properties. (To be continued.)

BLAST FURNACES

Fuel Economy in Blast Furnace Practice, T. C. Hutchinson. Blast Furnace, vol. 6, no. 10, Oct. 1918, pp. 419-420, 3 figs. Discussion concerning results obtained with working furnace model built for determination of efficient distribution of charge. Paper before British Iron & Steel Inst. (Concluded.)

COPPER

Bronzes

The Constitution of the Tin Bronzes, Samuel L. Hoyt. A.I.M.E., Bul., no. 144, Dec. 1918, pp. 1721-1727, 14 figs. Notes on progress made in establishing what happens over the upper heat effect.

Gases, Reducing

The Action of Reducing Gases on Hot Solid

Copper, Norman B. Pilling. Bul. Am. Inst. Min. Engrs., no. 142, Oct. 1918, pp. 1567-1580, 21 figs. Studies nature of action and conditions under which it occurs and gives graphs (obtained by experimentation) showing permeability of copper to H, steam, CO and CO_2.

Lead in Copper

The Spectroscopic Determination of Lead in Copper, C. W. Hill and G. P. Luckey. Bul. Am. Inst. Min. Engrs., no. 142, Oct. 1918, pp. 1581-1592, 4 figs. Details of apparatus and its standardization, and comparison of accuracy of quantitative spectroscopic method for determining small amounts of lead with that of standard electrolytic determination. Variations and other applications of method are found in Proc. Am. Electrochem. Soc. (1918), 32, 191, and in Met. & Chem. Engr. (1917), 17, 659.

Utah Copper Plant

The Utah Copper Enterprise, T. A. Rickard. Min. & Sci. Press, vol. 117, no. 22, Nov. 30, 1918, pp. 713-724, 16 figs. Flow sheet of mill; plan and section of Richards-Janney classifier as used in mill; flow sheet of primary and secondary crushing plants. (To be continued.)

FLOTATION

Mill Practice at Flotation Plant of Utah Leasing Co., H. H. Adams. Salt Lake Min. Rev., vol. 20, no. 15, Nov. 15, 1918, pp. 21-25, 4 figs. Work of reclaiming metal contents from old tailing dumps.

IRON AND STEEL

Cast Iron

The Prevention of Growth in Gray Cast Iron, J. E. Hurst. Iron Age, vol. 102, no. 19, Nov. 7, 1918, pp. 1144-1145, 3 figs. Causes of phenomenon; effect of entrance of oxidizing gases and formation of case; application of dies and permanent molds. Paper before Iron and Steel Inst., London, September, 1918. Also in Engineering, vol. 106, no. 2754, Oct. 11, 1918, p. 415, 3 figs.

Electrical Resistance

Electrical Resistance of Hardened Steel, E. D. Campbell. Engineering, vol. 106, no. 2757, Nov. 1, 1918, pp. 509, 2 figs. On rate of change at 100 deg. cent., and of ordinary temperatures in electrical resistance of hardened steel. Paper before Iron and Steel Inst.

Ingots

Making Sand-Cast Forging Ingots, W. L. Booth. Iron Age, vol. 102, no. 19, Nov. 7, 1918, pp. 1139-1140, 2 figs. Development of practice on Pacific Coast; replacing Eastern ingots; advantages claimed for sand mold. From article in October issue of Metal Trades.

Internal Stresses

Internal Stresses Developed in Metals and Alloys by Sudden Cooling (Efforts internes développés dans les métaux et alliages par l'effect d'un refroidissement rapide), M. Portevin. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 15, Oct. 7, 1918, pp. 531-533. Measurements of dimensional variations in steel specimens. Also in Revue Générale de l'Electricité, vol. 4, no. 18, Nov. 2, 1918, p. 652.

Open-Hearth Furnaces

The Principles of Open-Hearth Furnace Design, Charles H. F. Bagley. Engineering, vol. 106, no. 2754, Oct. 11, 1918, pp. 400-401, 2 figs. From paper before Iron and Steel Inst., Sept. 1918.

Rolling Mills

Blooming Mill Now Rolling Plates. Iron Trade Rev., vol. 63, no. 23, Dec. 5, 1918, pp. 1285-1288, 4 figs. Transformation at Baldt Works, New Castle, Del. How the plan was worked out.

Electric Rolling Mill Plant. Engineer, vol. 126, no. 3276, Oct. 11, 1918, pp. 312-314, 17 figs. Principles of speed control.

The Predetermination of Power Demands of Rolling Mills (Om bestämning och förutberäkning av energiatgangen vid valsverk), Frithiof Holmgren. Bihang till Jern-Kontorets Annaler, year 19, no. 10, Oct. 15, 1918, pp. 489-515, 6 figs.

Diagonals for Designing Rolls for Billet Mills, A. R. Mitchell. Iron Age, vol. 102, no. 20, Nov. 14, 1918, facing page 1198. Tables for determining dimensions of passes when width and corner radii of billets are given.

Steel Hardening

Further Experiments on Spontaneous Generation of Heat in Recently Hardened Steel, Charles F. Brush, Robert A. Hadfield and S. A. Main. Proc. Roy. Soc., vol. 95, no. A666, Oct. 7, 1918, pp. 120-138, 7 figs. Recapitulation of previous investigations; account of recent experimental work which was confined mainly to variations of heat treatment of one particular nickel-chromium steel; presentation of empirical law which seems to regulate approximately gradual diminution of evolution of heat.

See also MECHANICAL ENGINEERING, Fuels and Firing (Waste Heat), Heat Treating.

OCCLUDED GASES

Gases in Metals. Times Eng. Supp., no. 529, Nov. 1918, p. 243. Influence on mechanical properties; opinions of scientists, industrial research workers and manufacturers. Conference of Faraday Soc.

WASTE RECUPERATION

Recuperation and Utilization of Waste of Copper, Zinc, Lead, Tin, Aluminum and Their Alloys (La recupération et l'utilisazion des déchets de cuivre, zinc, plomb, étain, aluminium et de leurs alliages), Paul Raous. Génie Civil, vol. 73, no. 13, Sept. 28, 1918, pp. 251-255, 5 figs. Electrolytic processes for recuperation of tin; recuperation of aluminum; electrolytic separation of metals entering in an alloy. (Concluded.)

See also ELECTRICAL ENGINEERING, Power Applications (Furnaces).

Aeronautics

AEROPLANE PARTS

Stick Control

The Warner Duplex Stick Control. Aerial Age, vol. 8, no. 13, Dec. 9, 1918, p. 661, 3 figs. Brief description of hand and knee grips for use of pilots.

Tail

A Gotha Biplane Tail. Flight, vol. 10, no. 40, Oct. 3, 1918, pp. 1107-1108, 1 fig. Design consisting of two horizontal approximately triangular planes, top plane being supported on cabane of steel tubes, while sides of bottom plane are bolted to sides of body.

AEROSTATICS

Military

Military Aerostatics, H. K. Black. Aerial Age, vol. 8, nos. 6, 7 and 9, Oct. 21 and 28, and Nov. 11, 1918, p. 325, 1 fig., 371, 1 fig. and 475, 2 figs. Oct. 21: Balloon baskets. Oct. 28 and Nov. 11: Equipment of basket. (Continuation of serial.)

AIRCRAFT PRODUCTION

U. S. Navy

Naval Aircraft Factory at Philadelphia. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 465-470, 13 figs. Story of great industrial achievement of United States Navy.

APPLICATIONS

Exploration

The Possibility of Aerial Reconnaissance in the Himalaya, A. M. Kellas. Aeronautics, vol. 15, no. 257, Sept. 18, 1918, pp. 275-277. Fundamental facts and requirements of undertaking. Paper before Roy. Geog. Soc.

AUXILIARY SERVICES

Trucks

Building for the Aviation Service, M. E. Hoag. Am. Mach., vol. 49, no. 23, Dec. 5, 1918, pp. 1043-1044, 7 figs. Building a 3½-ton special truck for U. S. Aviation Signal Service. First article.

DYNAMICS

Ceiling

Elementary Considerations on the Ceiling of an Airplane (Données élémentaires sur le plafond d'un avion), André Lainé. l'Aérophile, year 26, nos. 17-18, Sept. 1-15, 1918, pp. 264-265. Points out convenience of high ceiling and means of attaining it.

On an Experience of the Flyer Gilbert (Sur une expérience du pilote Gilbert), F. Roux. l'Aérophile, year 26, nos. 17-18, Sept. 1-15, 1918, p. 263, 1 fig. How it happened that Eugène Gilbert maintained his plane stationary in air while machine was running at full speed.

Stability

Lateral Stability in Aeroplanes, C. Levick. Aerial Age, vol. 8, no. 13, Dec. 9, 1918, p. 660, 3 figs. Computation of effect of a roll on a machine in terms of dihedral angle of aerofoils. Also in Flight, vol. 10, no. 42, Oct. 17, 1918, p. 1165, 3 figs.

ENGINES

Austro-Daimler

The 200-Hp. Austro-Daimler Aero Engine. Engineer, vol. 126, nos. 3279 and 3280, Nov. 1 and 8, 1918, pp. 376-379, 10 figs, 393-394, 7 figs. Description of details, with principal data and illustrations. Also in Flight, vol. 10, nos. 44 and 45, Oct. 31 and Nov. 7, 1918, pp. 1217-1222, 10 figs., and 1255-1259, 12 figs.; Engineering, vol. 106, no. 2757, Nov. 1, 1918, pp. 488-492, 17 figs.; Aeronautics, vol. 15, no. 263, Oct. 30, 1918, pp. 403-417, 27 figs.

Design

The Design of Airplane Engines (II), John Wallace. Automotive Eng., vol. 3, no. 9, Oct. 1918, pp. 415-417 and 401, 3 figs. Comparison of rotary and fixed radial motors; trend of modern design; cooling of cylinders; indicator diagram; compression ratio. From Aeronautics. (Continuation of serial.)

History

Outline of History of Aviation Engine Production, H. H. Emmons. Aerial Age, vol. 8, no. 13, Dec. 9, 1918, pp. 662-665, 2 figs. Elementary training engines; development of Liberty 12; methods of production. Also in Motor Age, vol. 34, no. 23, Dec. 5, 1918, pp. 18-19 and 30, 3 figs.

Liberty

American Liberty Motor (Le moteur Américain Liberty). l'Aérophile, year 26, nos. 17-18, Sept. 1-15, 1918, p. 271. Abstract of description authorized by War Department. Also in Sci. Am., vol. 99, no. 23, Dec. 7, 1918, pp. 455 and 466, 4 figs.

Maybach

The 300-Hp. Maybach Aircraft Engine. Automotive Ind., vol. 39, nos. 18, 20 and 21, Oct. 31, Nov. 14 and 21, 1918, pp. 755-759, 8 figs., 840-843, 9 figs., 882-887, 5 figs. Technical description of largest German Aircraft engine model. Issued by Tech. Department, Aircraft Production, Ministry of Munitions. Nov. 14: Lubricating System; details of oil pumps; cooling and ignition systems; carburetor and fuel feed system. Nov. 21: Results of horsepower and fuel consumption tests; table of engine dimensions; general analysis of weights; chemical and physical analysis of material in various parts. Also in Automobile Engr., vol. 8, no. 119, Oct. 1918, pp. 285-295, 27 figs.; Flight, vol. 10, no. 39, Sept. 26, 1918, pp. 1084-1087, 2 figs.

Panhard

The Panhard—300 Hp. (Direct Type Aviation Motor), E. H. Sherbondy. Aerial Age, vol. 8, no. 6, Oct. 21, 1918, pp. 308-309, 5 figs. Motor with two rows, each of six cylinders, inclined 60 deg. to each other.

GLIDERS

An Interesting Biplane Glider, F. J. Camm. Aeronautics, vol. 15, no. 262, Oct. 25, 1918, p. 393. Chief dimensions and process of construction.

HISTORY

Langley

What Langley Did for the Science of Aviation (II). Automotive Ind., vol. 39, no. 17 and 18, Oct. 24 and 31, 1918, pp. 714-718 and 728, 10 figs., and 761-765, 7 figs. Experiments with rubber-driven models and others using compressed air, carbonic acid gas and electric batteries; adoption of steam as source of power. Oct. 31: Experiments with quarter-size and man-carrying aerodromes. (To be continued.)

INSTRUMENTS

Barograph

German Barograph No. 1623, Range 0 to 8000 m. Flight, vol. 10, no. 42, Oct. 17, 1918, pp. 1167-1168, 6 figs. General remarks on details of construction. Also in Aeronautics, vol. 15, Oct. 23, 1918, pp. 382-384, 6 figs.

Instruments for Air Use, W. A. Robson. Sci. Am. Supp., vol. 86, no. 2235, Nov. 2, 1918, p. 285. From Flight.

MATERIALS OF CONSTRUCTION

Steel Tubes

Steel Tubes, Tube Manipulation, and Tubular Structures for Aircraft, W. W. Hackett and A. G. Hackett. Flight, vol. 10, no. 44, Oct. 31, 1918, pp. 1233-1235. Tapered tubes; tubular liners or reinforcements; tubular joints in aircraft construction; tests on soldered joints; brazing; welding; rust prevention. (Concluded.) Also in Automotive Eng., vol. 3, no. 9, Oct. 1918, p. 396 and (discussion) pp. 397-398.

See also MECHANICAL ENGINEERING, Measurements (Permeability).

METEOROLOGY

Meteorology in Relation to Aeronautics (I), W. H. Dines. Sci. Am. Supp., vol. 86, no. 2239, Nov. 30, 1918, pp. 351-352. Review of data required by an aviator when in the air. Paper before Aeronautical Soc. of Gt. Britain. From Aeronautical Jl.

MILITARY AIRCRAFT

British

Some Recent Types of Allied Military Planes. Automotive Ind., vol. 39, no. 17, Oct. 24, 1918, pp. 706-707, 4 figs. General features of Spad single-seater tractor scout, Vickers F B-14, long-distance reconnaissance tractor biplane, Sopwith "Hippo" two-seater fighter, and Avro training machine.

German

German Aircraft Times Eng Supp., no. 527, Sept. 1918, p. 198. Abstract of five reports of Technical Department, Aircraft Production, Ministry of Munitions, describing Maybach engine, Rumpler two-seater biplane, Hannoveraner biplane, an armored machine, and Pfalz scout.

MODELS

Model Construction

Model Aeroplane Building as a Step to Aeronautical Engineering. Aerial Age, vol. 8, nos. 6, 7, 8 and 9, Oct. 21, 28 and Nov. 4, 11, 1918, p. 377, 7 figs., 389, 1 fig., 433 and 483, 1 fig. Oct. 21: Construction of vertical stabilizer. Oct. 28: Designing and building of a man-carrying aeroplane. Nov. 4 and 11: Calculation of sustaining power and resistance of wings and explanation of table giving aerodynamic laboratory tests. (Continuation of serial.)

Model Aeroplanes (XVI), F. J. Camm. Aeronautics, vol. 15, no. 258 and 261, Sept. 25, Oct 16, 1918, p. 300, 1 fig., 369, 2 figs. Details of a tractor monoplane. Oct. 16: Notes on attaching elastic and on manner of flying model.

Model Testing

The Theoretical Basis of Model Strength Tests for Aeroplane Structures, W. L. Cowley and H. Levy. Aerial Age, vol. 8, no. 6, Oct. 21, 1918, pp. 322-323. Application of principle of homogeneity of dimensions to determination of strength of structure.

PLANES

A. E. G.

A. E. G. Armoured Aeroplane. Engineering, vol. 106, no. 2754, Oct. 11, 1918, pp. 416-417, 15 figs. Principal data and description, with details of construction illustrated.

The Fokker Biplane, Type D VII. Flight, vol. 10, nos. 40, 41 and 42, Oct. 3, 10, and 17, 1918, pp. 1109-1116, 1142-1144 and 1161-1164, 23 figs. Data relating to performance and detailed particulars of weights. Issued by Technical Department, Aircraft Production, Ministry of Munitions. Also in Aerial Age, vol. 8, no. 8, Nov. 4, 1918, pp. 424-427, 20 figs.; l'Aérophile, year 26, nos. 17-18, Sept. 1, 1918, pp. 257-262, 10 figs.; Aeronautics, vol. 15, no. 259, Oct. 2, 1918, pp. 310-316, 23 figs.

A. R.

The French A. R. Biplane. Aerial Age, vol. 8, no. 7, Oct. 28, 1918, pp. 374-375, 6 figs. Particulars of two-strutter biplane of 13.3 m. span which has its fuselage supported between planes on ash struts.

Berg

The Austrian Berg Single-Seater. Flight, vol. 10, no. 44, Oct. 31, 1918, pp. 1225-1227, 7 figs. Mounting of 200-hp. Austro-Daimler engine with which plane is equipped; tanks; instruments; control; undercarriage. (Continuation of serial.)

Continental

The Continental Kb 3T Training Tractor, John F. McMahon. Aerial Age, vol. 8, no. 6, Oct 21, 1918, pp. 316-317 and 345, 4 figs. General specifications of machine designed for cheap construction by the Continental Aircraft Corporation.

Halberstadt

Report on the Halberstadt Fighter. Flight, vol 10, no. 41, Oct. 10, 1918, pp. 1133-1141, 38 figs. Details of performance and construction. Issued by Technical Department, Aircraft Production, Ministry of Munitions. Supplementing brief description given in issue of Aug. 1. Also in Engineer, vol. 126, no. 3276, Oct. 11, 1918, pp. 302-304, 25 figs.

Pfalz

Report on the Pfalz Single-Seater (G141). Aeronautics, vol. 15, no. 257, Sept. 18, 1918, pp. 270-271, 22 figs. Particulars and performance of German scout with streamline-shaped fuselage. By Technical Department, Aircraft Production, Ministry of Munitions.

Roland

The Roland Chaser D II, G. Douglas Wardrop. Aerial Age, vol. 8, no. 6, Oct. 21, 1918, pp. 310-312, 9 figs. Construction of fuselage, planes, tail, engine, and undercarriage.

Siemens-Schuckert

A New German Chaser. Flight, vol. 10, no 39, Sept. 26, 1918, p. 1083, 2 figs. Characteristics of Siemens-Schuckert biplane.

Sopwith

The Sopwith "Camel." Automotive Ind., vol. 39, no 19, Nov. 7, 1918, pp. 790-791, 6 figs. Description of late model of British scout plane. Translated from German aircraft publication.

Zeppelin

The Zeppelin Biplane, Jean Lagorgette. Sci. Am. Supp., vol. 86, nos. 2237 and 2238, Nov 16 and 23, 1918, pp. 316-319 and 334-335, 8 figs. Description of German bombing machine 134 ft. long. From Aeroplane.

PRODUCTION

Standardization

Effect of Changes on Airplane Output. Ind. Man., vol. 56, no. 5, Nov. 1918, pp. 375-377. Manufacturers must abandon idea of standardized production.

PROPELLERS

Analysis

Notes on Airscrew Analysis (III), M. A. S. Riach. Aeronautics, vol. 15, no. 257, Sept. 18, 1918, pp. 265-266. Outlines process by which experimental results on airscrews are analyzed and compared with their respective calculated performances. (Concluded.)

Calculations

Calculating Airplane Propeller Strength and Efficiency (II), F. W. Caldwell. Automotive Eng., vol. 3, no. 9, Oct. 1918, pp. 402-405. Limit of ceiling, comparison of conventional designs; calculations of efficiency during climbing; calculations for propeller chart. (Concluded.)

SPECIFICATIONS, AEROPLANE

U. S. Navy

Navy Department Airplane Specifications. Jl. Soc. Automotive Engrs., vol. 3, no. 5, Nov. 1918, pp. 325-329. Issued for use in connection with contracts and submission to Navy of new and undemonstrated designs.

TRANSATLANTIC FLIGHT

Transatlantic Flight, Frithiof G. Ericson. Jl. Soc. Automotive Engrs., vol. 3, no. 5, Nov. 1918, pp. 319-321. Favorable routes; requirements of airplane; flight endurance. From Aviation.

Marine Engineering

AUXILIARY MACHINERY

Boats

Boat Lowering Appliances. J. R. Hodge. Tran. Inst. Marine Engrs., vol. 30, Aug. 1918, pp. 123-127, 4 figs and (discussion) 127-136, 1 fig. Type of disengaging gear designed to deal simultaneously and automatically at both ends of boat, to free it from davit falls or tackles as soon as boat is water-borne.

General Rules and Regulations Prescribed by the Board of Supervising Inspectors as Amended at Board Meeting of January, 1918. Department of Commerce, Steamboat-Inspection Service, Aug. 1, 1918, 147 pp., 5 figs. Rules for boiler plate, boilers and attachments, boats and their appliances, steamers, barges and duties of inspectors; list of instruments, machines and equipments approved for use on vessels.

Diving Bell

Diving Bell in Use at Halifax Ocean Terminals, J. J. Mac Donald. Jl. Eng. Inst. Can., vol. 1, no. 6, Oct. 1918, pp. 252-262, 14 figs. Outline of function design, construction and operation; formulation of principles of design proposed as applicable to future work; survey of fields of activity where plant of this type promises applicability.

SALVAGE

Salvage Methods

Salvage of Wrecked Ships (Le sauvetage des navires coulés), A. Poidloué. Génie Civil, vol. 73, no. 13, Sept. 28, 1918, pp. 241-244, 6 figs. Review of processes used and considerations on probability of future developments.

Turning Vessel

Salvaging the Steamship St. Paul, Charles M. Horton. Int. Mar. Eng., vol. 23, no. 11, Nov. 1918, pp. 644-648, 6 figs. Methods used in turning vessel; character of problems solved; placing patch under difficulties.

SHIPS

Canada

A Canadian Shipbuilding Industry, Thomas Cantley. Can. Min. Inst., bul. no. 80, Dec. 1918, pp. 995-1000. Excerpts from paper at 20th annual meeting of the Institute. The question of developing steel shipbuilding in Canada.

Concrete Ships

Concrete Ship Design, R. J. Wig. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, pp. 15-17, 9 figs. Summary of conclusions on advisability of constructing concrete ships reached by Concrete Ship Department, Emergency Fleet Corporation. From Special Report to Chairman of Shipping Board. Also in Eng. News-Rec., vol. 81, no. 20, Nov. 14, 1918, pp. 903-904, 3 figs.

Different Types of Framing in Two New Government Reinforced-Concrete Ships. Eng. News-Rec., vol. 81, no. 22, Nov. 28, 1918, pp. 986-989, 6 figs. 7500-ton oil tanker has close-spaced frames with vertical and horizontal reinforcing in shell, while 2500-ton schooner barge has long-span framing system with diagonal shell reinforcement.

Reinforced-Concrete Barges (Barca de hormigon armado), Julio Murúa. Revista de Obras Publicas, year 66, no. 2245, Oct. 3, 1918, pp. 493-497, 10 figs. Calculations of design for 60-ft. barge.

Reinforced Concrete Vessels, Walter Pollock. Can. Engr., vol. 35, no. 17, Oct. 24, 1918, pp. 367-373, 5 figs. Considerations of design and ideals aimed by builders; strength; advantages and disadvantages; classification rules; structural details of hull, steelwork and fittings. Paper before British Instn. of Naval Architects.

Duct Keels

Improvements in the Construction of Ships, E. F. Spanner. Shipbuilding and Shipping Rec., vol. 12, no. 9, Nov. 7, 1918, pp. 451-452. Discusses question of duct keels. Before Instn. Engrs. & Shipbuilders.

Isherwood Framing

Large Freighters of Isherwood Framing Adapted to Bridge-Shop Fabrication. Eng. News-Rec., vol. 81, no. 19, Nov. 7, 1918, pp. 853-857, 4 figs. Problems worked out by coöperation of naval architect and engineer of barge shop; 200 tons weight saved; time gained in detailing; all molded work done in large shop at shipyard.

Reduction Gearing

Italian Reduction-Geared Turbine Cargo-Steamship "Ansaldo I." Shipbuilding & Shipping Rec., vol. 12, nos. 19 and 20, Nov. 7 and 14, 1918, pp. 447-450, 13 figs., 470-471, 4 figs. Principal dimensions, plans and photographs.

Resistance

Effect of Appendages on Resistance and Propulsion. Shipbuilding & Shipping Rec., vol. 12, no. 19, Nov. 7, 1918, pp. 452-453, 2 figs. Account of Luke's experiments with various angles of bossing, with outward- and inward-turning screws; values of wake fractions and hull efficiencies; resistance compared with resistance of naked model. (Concluded.)

Rolling

The Rolling of Ships. Sci. Am. Supp., vol. 86, no. 2236, Nov. 9, 1918, p. 299. Factors upon which natural period of roll of a ship depends; results obtained by Froude with his apparatus to record angles of roll. From Shipping World.

Standardized Ships

Structural Steel Standardized Cargo Vessels, Henry R. Sutphen. Inst. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 695-698, 1 fig. How quantity production was met.

Stresses

Investigation of Shearing Force and Bending Moment on Ship Structures, A. M. Robb. Int. Mar. Eng., vol. 23, no. 11, Nov. 1918, pp. 637-642, 8 figs. Moderate amplitudes of heave; sagging bending moment; pitching treated graphically; effect of rotational acceleration. (Second article.)

Tow Boats

Plans and Specifications of New Wood Tow Boats. Inst. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 673-674, plate, 1 fig. Built for hard service.

Wooden Ships

Building Wooden Ships for the Emergency Fleet Corporation, E. A. Suverkrop. Am. Mach., vol. 49, no. 20, Nov. 14, 1918, pp. 883-887, 11 figs. Planking and interior work. Third article.

YARDS

Canada

Canadian Vickers Shipbuilding Works at Montreal. Engineering, vol. 106, no. 2754, Oct. 11, 1918, pp. 395-396, 12 figs. Illustrated description of shipbuilding in Canada.

Departamental Organization

Effective Arrangement of Departments in Shipyard Organization, G. F. S. Mann. Int. Mar. Eng., vol. 23, no. 11, Nov. 1918, pp. 615-617. Shipyard divisions; relations between organization departments and production departments; duties of chief engineer.

New Lake Shipyard has Side-Launching Ways Under Cover. Eng. News-Rec., vol. 81, no. 19, Nov. 7, 1918, pp. 839-841, 3 figs. Ships built at Ferguson yard fabricated in company's shops two miles away; berths covered with cantilever roof served by semi-gantry crane.

Great Lakes

Great Lakes Yards Lead Coast Districts in Building Ocean-Going Ships. Eng. News-Rec., vol. 81, no. 22, Nov. 28, 1918, pp. 978-980, 4 figs. Canal-size steamers produced in large numbers; spirit of coöperation; yard capacity doubled; no outside fabrication; equipment of varied character; labor shortage.

Shooter's Island

Methods Used at Shooter's Island for Constructing Standard Ships, Charles M. Horton. Int. Mar. Eng., vol. 23, no. 11, Nov. 1918, pp. 618-624, 13 figs. Serving individual ways; method for increasing output: well-lighted boiler shop; handy plate-lifting clamp.

See also ELECTRICAL ENGINEERING, Power Applications (Ship Propulsion); MECHANICAL ENGINEERING, Internal-Combustion Engines (Marine Engines).

Organization and Management

ACCOUNTING

Army

Accounting Systems in Army Camps, E. J. Holmes. Jl. Actcy., vol. 26, no. 6, Dec. 1918, pp. 429-435. Explains the system used by the U. S. Army in connection with the disbursement of funds appropriated by Congress.

Carrying on with the Accountants in the American Expeditionary Forces, C. B. Holloway. Jl. Actcy., vol. 26, no. 6, Dec. 1918, pp. 412-416. Specific operations carried on by the accounting personnel.

Cost Accounting

Cost Accounting to Aid Production (III), G. Charter Harrison. Indus. Management, vol. 56, nos. 5 and 6, Nov. and Dec. 1918, pp. 456-463, 2 figs. and 391-398, 1 fig. Emphasizes necessity of cost-accounting system and illustrates its planning with diagram showing basic features of simple system for a business manufacturing various kinds of standard machines. (Continuation of serial.)

Duties of a Factory Cost Accountant, Joseph Gill. Jl. Actcy., vol. 26, no. 6, Dec. 1918, pp. 441-449. A thesis presented at the May examinations of the Am. Inst. of Accountants. Routine work of cost accountants.

Setting Production Standards for Industrial Accounting and Engineering, F. J. Knieppel. Jl. of Accountancy, vol. 26, no. 5, Nov. 1918, pp. 361-375. Explains methods of determining four basic standards.

Inventories

Verification of Inventories, A. L. Philbrick. Jl. Actcy., vol. 26, no. 6, Dec. 1918, pp. 417-428. Briefly outlines the work of the auditor and his responsibilities. Difficulties involved in the verification of the inventory.

Mail Order

Mail Order Accounting, Harry L. Cavanagh. Jl. Actcy., vol. 26, no. 6, Dec. 1918, pp. 436-440. A thesis presented at the May examinations of the Am. Inst. of Accountants.

Power House

Economics of the Power House, L. W. Alwyn-Schmidt. Power Plant Eng., vol. 22, no. 23, Dec. 1, 1918, pp. 949-952. Problem of power-house accounting approached from point of view of economist.

EDUCATION

Training of Employees

Packard Training Schools for Employees, D. G. Stanbrough. Indus. Management, vol. 56, no. 5, Nov. 1918, pp. 378-382, 13 figs. Four schools operated; for men, women, instructors for women and for job setters and foremen.

Vestibule School of Lincoln Motor Co., J. M. Eaton. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 452-455, 10 figs. Equipment of training rooms; system of instruction in machine-shop practice.

Soldiers

Vocational Training for Returned Soldiers. Jl. Eng. Inst. Can., vol. 1, no. 7, Nov. 1918, pp. 333-334. Work being done at Toronto and McGill Universities.

University

The Khaki University. Can. Min. Inst., bul. no. 80, Dec. 1918, pp. 985-989. Letter from F. D. Adams giving an account of the work and plans for future development.

FACTORY MANAGEMENT

Boiler Shop

Business Equipment in the Boiler Shop, Edwin L. Seabrook. Boiler Maker, vol. 18, no. 11, Nov. 1918, pp. 305-307. Suggests items of business conduct in boiler making plant.

Employment Manager

The Employment Manager, Edward D. Jones. Wood-Worker, vol. 37, no. 9, Nov. 1918, pp. 38-39. Organization and direction of course offered gratis to representatives of manufacturers by Management Division of War Industries Board.

The Employment Manager in Our Shipyards, Edward B. Jones. Int. Mar. Eng., vol. 23, no. 11, Nov. 1918, pp. 612-614. Duties of general executive; importance of schools; wage system and ideal service; psychology of mass action.

Foremen

Instructions to Assistant Foremen, George H. Shepard. Indus. Man., vol. 56, no. 5, Nov. 1918, pp. 403-407. Prepared by plant working extensively on governmental orders to inspire and guide minor executives.

Industrial Organization

After-War Economics of Engineering. Times Eng. Supp., no. 529, Nov. 1918, pp. 225-226. Sugests that plants review their methods of manufacture and adopt convenient modifications when necessary. Illustrations of practical procedure by reference to foundry work

Industrial Organization as it Affects Executives and Workers, Charles E. Knoeppel. Jl. Am. Soc. Engrs., vol. 40, no. 12, Dec. 1918, pp. 1031-1033. Proposes rules of efficient organization for practical guidance of executives in developing system of industrial relationship. Presented at annual meeting of the Soc.

Management—The Solution of the Shipbuilding Problem, W. L. Churchill. Indus. Management, vol. 56, no. 5, Nov. 1918, pp. 361-366, 2 figs. Based on study of conditions in 20 shipyards and pointing to management as developed recently in other industries as proper solution to problems.

Practical System in Factory Operations, M. H. Potter. Can. Machy., vol. 20, no. 20, Nov. 14, 1918, pp. 559-560, 6 figs. Forms of charts developed from investigation of actual case.

Scientific Management Simplified, Malcolm Keir. Sci. Monthly, vol. 7, no. 6, Dec. 1918, pp. 525-529. Adaptability of scientific management to industry; fundamental elements of scientific management.

Industries

New Industries, H. W. Gepp. Aust. Min. Std., vol. 60, no. 1564, Oct. 31, 1918, pp. 686-688. Address with discussion before Soc. of Chem. Ind., Melbourne. Essential factors in the successful development of new industries in a young country.

Mechanical Department

Coördination in the Mechanical Department, W. U. Appleton. Ry. Rev., vol. 63, no. 22, Nov. 30, 1918, pp. 773-774. Recommendations for system and harmony within department and with other departments. Paper before Canadian Ry. Club, Oct. 1918.

Rate Setting

Mastering Power Production, Walter N. Polakov. Ind. Man., vol. 56, no. 5, Nov. 1918, pp. 399-403, 6 figs. Conservation of labor, power and fuel in relation to rates. Tenth article.

Time Studies for Rate Settings on Gisbolt Boring Mills, Dwight V. Merrick. Indus. Management, vol. 56, no. 5, Nov. 1918, pp. 409-411, 1 fig. Fifth article.

Routing

About the Handling of Mill Work (II), Chas. Cloukey. Wood-Worker, vol. 37, no. 9, Nov. 1918, pp. 23-24, 1 fig. Part which routing of work through mill has in economical production.

Task Setting

The Human Factor in Task Setting, W. E. Camp. Indus. Management, vol. 56, no. 5, Nov. 1918, pp. 372-374, 1 fig. Chief conditions that affect factor; how they are evaluated; how to predetermine proper allowance.

Tool Department

Continuous Tooling. Times Eng. Supp., no. 527, Sept. 1918, p. 183. Suggests a means of obtaining increased output from machine-shop tools.

Tool Department of Winchester Works. Iron Age, vol. 102, no. 19, Nov. 7, 1918, pp. 1129-1133, 4 figs. Virtually on factory production basis, workers being trained for single type operation; preparation section's important functions.

See also MARINE ENGINEERING, Yards; AERONAUTICS, Production.

FINANCE AND COST

Capital

Capital: Its Waste and Its Conservation, Archibald P. Main. Gas Jl., vol. 144, no. 2894, Oct. 29, 1918, pp. 249-251, and (discussion) pp. 251-252. Means by which author judges British industry can make best use of available credit and financial accommodation. Paper before Soc. of British Gas Industries.

INSPECTION

Graphic Control

Graphic Production Control, C. E. Knoeppel. Indus. Management, vol. 56, nos. 5 and 6, Nov. and Dec. 1918, pp. 383-390, 17 figs, 496-502, 14 figs. Controlling materials and operations. Fourth Article.

Production Records

Keeping Close Track of Shop Operation, Robert I. Clegg. Iron Age, vol. 102, no. 21, Nov. 21, 1918, pp. 1251-1253, 6 figs. Records of production and labor bulletined to management; reports with alarm-clock attachment.

Supervision

Mechanical Department Supervision, Frank McManamy. Ry. Mach. Eng., vol. 92, no. 11, Nov. 1918, pp. 597-598. Better supervision and more of it needed to keep up shop output. From paper before New York Ry. Club.

See also MECHANICAL ENGINEERING, Foundries (Supervision).

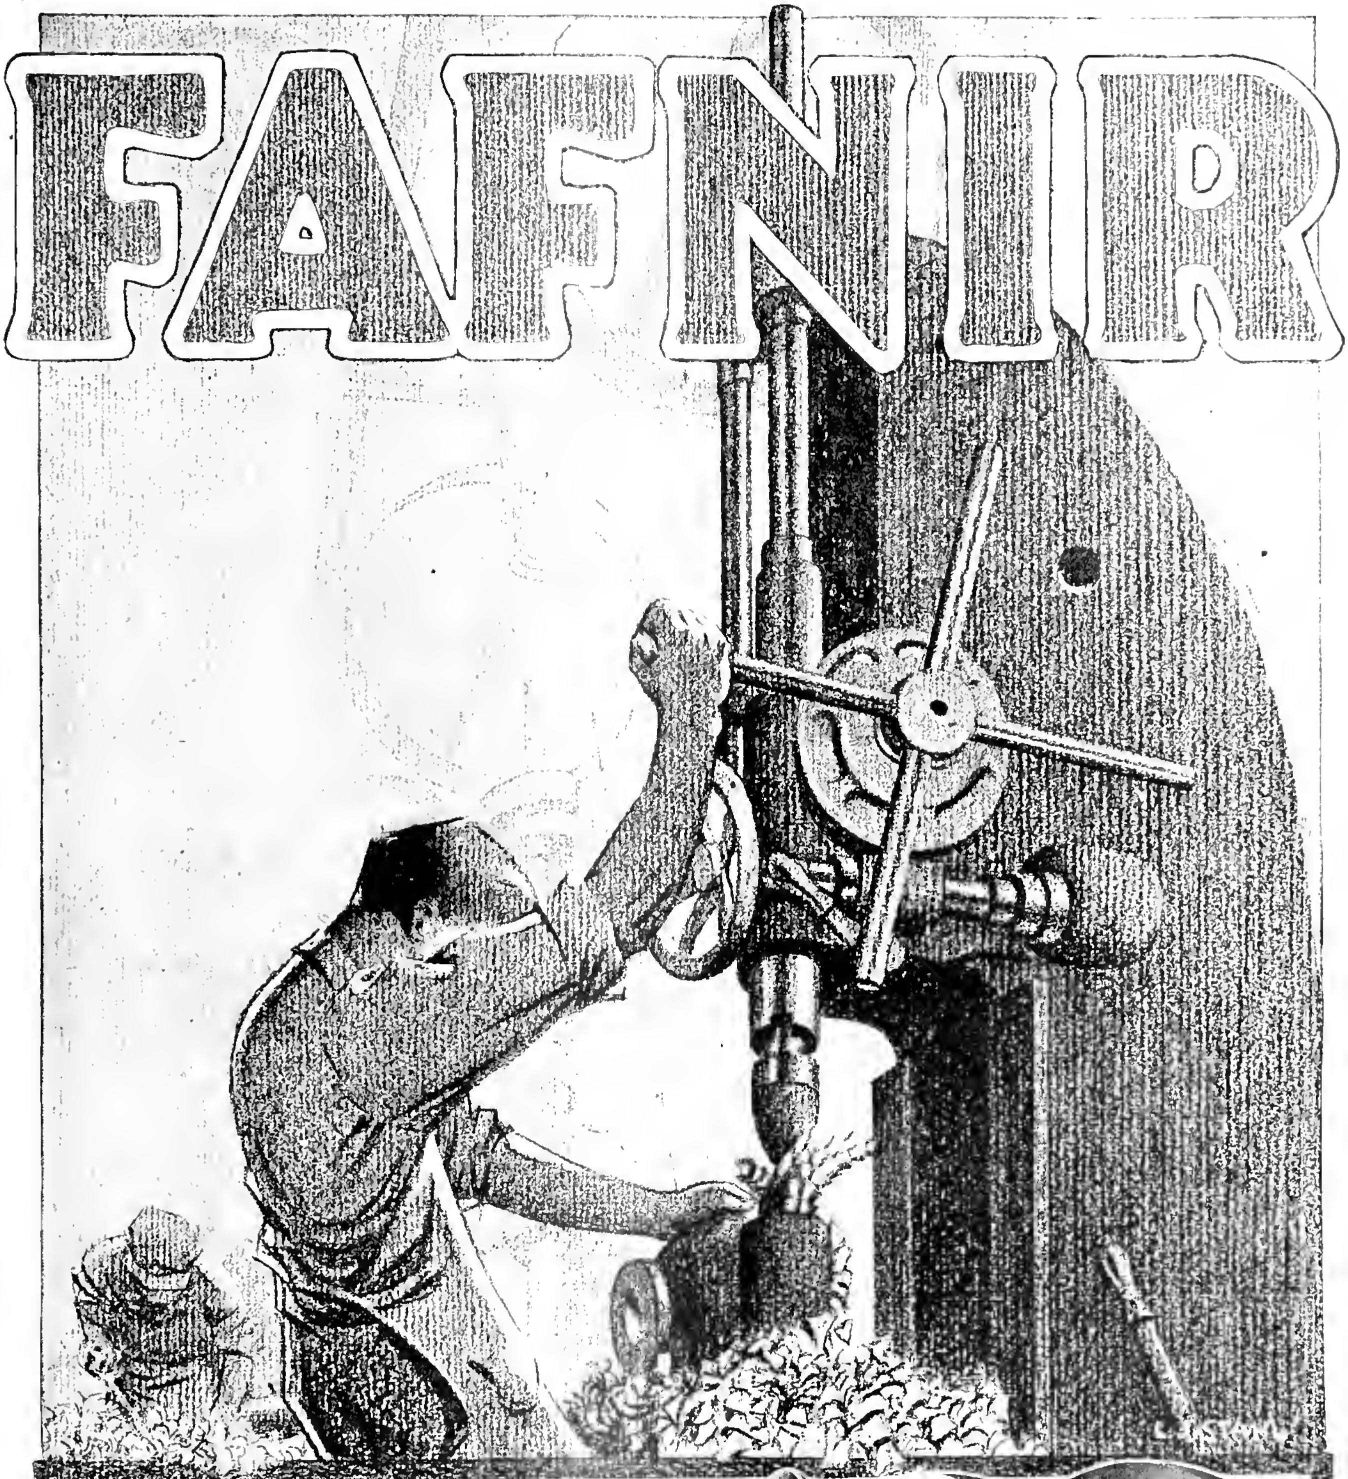
LABOR

Bargaining (including collective systems)

Agreement vs. Bargaining, Harry Tipper. Automotive Ind., vol. 39, no. 19, Nov. 7, 1918, pp. 784-785. Claims confidence between employer and employee is impossible so long as both base their relations upon their ability to take advantage of a bargain.

Handling Employment Relations Without Help from the Outside. Automotive Ind., vol. 39, no. 17, Oct. 24, 1918, pp. 722-723, 1 fig. Collective-bargaining plan for handling all matters relating to wages, hours of labor, discipline, discharges and grievances.

Important Phases of the Labor Problem, Magnus W. Alexander. Iron Age, vol. 102, nos. 21 and 22, Nov. 21 and 28, 1918, pp.



DRILL THRUST

One of the chief sources of possible power loss experienced in connection with the operation of heavy duty drills is found in the excessive friction which results when inadequate provision is made for carrying the severe thrust load reacting upward through the spindle. For this application the ball bearing is far more efficient than any other type.

Fafnir Thrust Ball Bearings are standard in the products of many prominent drill manufacturers.

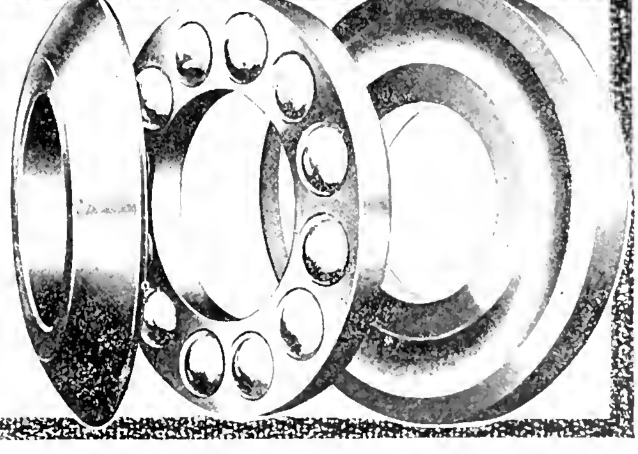
THE FAFNIR BEARING COMPANY

Conrad Patent Licensee

New Britain, Conn.

DETROIT Office: 752 David Whitney Bldg.

CHICAGO Office: 1919 So. Michigan Ave.



1258-1261 and 1322-1325. Problems of pensions and insurance; profit sharing in industry; adjustment of labor disputes; working conditions; hours of work. Nov. 21: Recruiting of men; collective bargaining discussed.

Bonuses

Paying Bonuses to Power Plant Employees, Frederick L. Ray. Nat. Engr., vol. 22, no. 10, Oct. 1918, pp. 493-495, and (discussion) pp. 495-497. Account of system followed by Milwaukee Elec. Ry. & Light Co. Paper before Nat. Assn. of Stationary Engrs.

British Labor Administration

Labor Administration, Edward T. Elbourne. Engineer, vol. 126, nos. 3276, 3278, 3279, 3280, Oct. 11 and 25, Nov. 1 and 8, 1918, pp. 299-300, 348-350, 2 figs., 365-367, 4 figs., 388-390, 1 fig. Oct. 25: Women; Nov. 1: Time office (men); Nov. 8: Methods of Remuneration.

Dilution

Labor Dilution as a National Necessity, Frederick A. Waldron. Jl. Am. Soc. Mech. Engrs., vol. 40, no. 12, Dec. 1918, pp. 1033-1035. After referring to work done by British Bureau of Labor Dilution writer outlines scope of labor dilution as necessary application to national recources of U. S. Presented at annual meeting of society.

Employment Department

Employment Department Routine of the Curtiss Aeroplane & Motor Corp., Charles E. Fouhy. Ind. Man., vol. 56, no. 5, Nov. 1918, pp. 412-416, 17 figs. Routine and forms of employment department.

Industrial Relations

Employment of Labor, Dudley R. Kennedy. Jl. Am. Soc. Mech. Engrs., vol. 40, no. 12, Dec. 1918, pp. 1030-1031. Activities of Industrial Relations Department of Hog Island plant in connection with securing and maintaining a force of 35,000 employees and providing for their needs and comfort. Presented at annual meeting of society.

Fundamental Factors in Sound Industrial Relations, H. T. Wailer. Ind. Management, vol. 56, no. 5, Nov. 1918, pp. 367-371, 8 figs. Seven factors discussed by author and illustrated by cartoons interpreting vital truth.

Use of Non-Financial Incentives in Industry, Robert B. Wolf. Jl. Am. Soc. Mech. Engrs., vol. 40, no. 12, Dec. 1918, pp. 1035-1038, 2 figs. Account of instances where personal interest has been developed in workmen by supplying foremen with information upon costs, methods of operation, possibilities in direction of economy and efficiency, etc. Presented at annual meeting of society.

Lunch Rooms

Feeding Employees at a Steel Plant. Iron Age, vol. 102, no. 19, Nov. 7, 1918, pp. 1136-1138, 2 figs. Reasons for abolishing dinner pail; management of lunchroom; auxiliary room for foreigners; commissary.

National War Labor Board

The War Labor Board and the Living Wage, Frank P. Walsh. Survey, vol. 41, no. 10, Dec. 7, 1918, pp. 301-303. Account of origin of National War Labor Board, its purpose and achievements.

Profit Sharing

A Tested Profit Sharing Plan, Dale Wolf. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 486-488, 3 figs. Average of 46 per cent of company's profits are distributed to employees.

Soldiers

Returned Soldiers Make Very Good Welders, W. F. Sutherland. Can. Machy., vol. 20, no. 22, Nov. 28, 1918, pp. 618-619, 2 figs. Outline of work done by training school.

The Employment of the Returned Soldier. Can. Machy., vol. 20, no. 20, Nov. 14, 1918, pp. 561-562. Résumé of problem as viewed by English correspondent. From Times Eng. Supp.

The Industrial Restoration of Disabled Soldiers, Bert J. Morris. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 477-481, 4 figs. Review of accomplishments of other nations and notes on organizations preparing to reëducate American soldiers.

Turnover

Interpreting Labor Turnover, Luther D. Burlingame. Am. Mach., vol. 49, no. 19, Nov. 7, 1918, pp. 855-858, 1 fig. Discusses real meaning and how it should be computed.

Women

Women in the Machine Shop, S. A. Hand. Am. Mach., vol. 49, no. 23, Dec. 5, 1918, pp. 1035-1037, 9 figs. Successful experience of large firm of machine tool builders in employment of women workers.

Women Workers

Women in the Service of the Railways, Pauline Goldmark. Ry. Age, vol. 65, no. 23, Dec. 6, 1918, pp. 1016-1018. Used in a great variety of work. Address before Labor Reconstruction Conference, Academy of Political Science, N. Y.

LEGAL

Boiler Contracts

Construing Boiler Contracts, A. L. H. Street. Power, vol. 48, no. 22, Nov. 26, 1918, pp. 765-766. Case reported in the Maryland Court of Appeals, bearing on obligations of manufacturer under contract for installation of boilers according to particular specifications.

Casual Employment

What Constitutes Casual Employment? Chesla C. Sherlock. Am. Mach., vol. 49, no. 19, Nov. 7, 1918, pp. 850-852. Discussion of certain legal interpretations.

Contributory Negligence

Disobedience of Orders by Employees and Its Relation to Compensation, Chesla C. Sherlock. Am. Mach., vol. 49, no. 22, Nov. 28, 1918, pp. 980-982. Review of some court decisions.

Floors, Slippery (accidents from)

Injuries Caused by Slippery Floors, Chesla C. Sherlock. Power, vol. 48, no. 22, Nov. 26, 1918, pp. 790. Some court decisions.

Simple Tools (accidents from)

Liability in the Use of Simple Tools, Chesla C. Sherlock. Am. Mach., vol. 49, no. 21, Nov. 21, 1918, pp. 939-940. Some legal aspects of employers' liability in use of simple tools.

LIGHTING

Leather Industry

Need for Improved Lighting in the Leather Industry, F. H. Bernhard. Elec. Rev., vol. 73, no. 20, Nov. 16, 1918, pp. 759-765, 7 figs. Tenth of series of articles on lighting in industries.

Lighting (General)

Daylight vs. Sunlight in Sawtooth-Roof Construction, W. S. Brown. Jl. Am. Soc. Mech. Engrs., vol. 40, no. 12, Dec. 1918, pp 1025-1029, 5 figs. Empirical research of amount of direct sunlight and intensity of daylight to be admitted on working plane in sawtooth construction; equation to determine time of admission of direct sunlight and number of hours of its duration with given orientation of sawtooth buildings and slope of lighting area; influence of size and slope of sawtooth lighting area on relative intensity of daylight from northern sky; examples illustrating manner of computing amount of diffused light entering building under several conditions. Presented at annual meeting of the Soc.

Elements of Illuminating Engineering (III), Ward Harrison. Elec. Eng., vol. 52, no. 2, Aug. 1918, pp. 30-34, 4 figs. Essentials in illumination design—coefficients of utilization, location of light sources, and recommended minimum spacings and minimum heights above plan of illumination for various units.

Lighting in Its Relation to the Eye, C. E. Ferree and G. Rand. Proc. Am. Phil. Soc., vol. 57, no. 5, 1918, pp. 440-478, 9 figs. Report of work of sub-committee on Hygiene of the Eye of Am. Medical Assn., involving an extensive experimentation on effect of different lighting conditions on eye, and investigation of factors in lighting situation causing eye to lose in efficiency and experience discomfort.

Some Modern Methods of Lighting, Geo. H. Stickney. Nat. Engr., vol. 22, no. 10, Oct. 1918, pp. 469-477, 7 figs., and (discussion) pp. 477-479 Analysis of elements of lighting systems required by factories, offices and stores. Paper before Nat. Assn. of Stationary Engrs.

War-Time Lighting Economies. Elec. World, vol. 72, no. 19, Nov. 9, pp. 885-887. Salient features of report prepared by War Service Committee of Illuminating Engineering Society for U. S. Fuel Administration; fallacies to be avoided; making maximum use of daylight.

Reflecting and Diffusing Light

Reflecting and Diffusing Light, Ward Harrison. Textile World Jl., vol. 54, nos. 18, 20, 21 and 22, Nov. 2, 16, 23 and 30, 1918, pp. 61 and 71, 4 figs., 25-27, 1 fig., 59-63, 5 figs., and 33, 5 figs. Properties of accessories necessary for good industrial illumination.

Steel Mills

Better Lighting of Iron and Steel Mills and Fabricating Plants, F. H. Bernhard. Elec. Rev., vol. 73, no. 22, Nov. 30, 1918, pp. 841-845, 7 figs. Eleventh of series of articles on improvement of lighting in industries.

PUBLIC REGULATION

Government Trading

The Functions of the Government in Relation to Industry, W. L. Hichens. Iron & Steel Trades Jl., nos. 3099 and 3100, Nov. 2 and 9, 1918, pp. 488-489 and 514. Examination of advisability of carrying out suggestions that the Government engage in trading undertakings.

RECONSTRUCTION

Electrical Industry

Problems of the Reconstruction Era. Elec. World, vol. 72, no. 19, Nov. 9, 1918, pp. 877-878. Taking effective part in great world war, this country will necessarily be powerful factor in succeeding period; closer coöperation in electrical industry advocated.

Export Trade

Reconstructing Our Business Fabric. Shipping, vol. 5, no. 8, Nov. 23, 1918, pp. 15-16, 1 fig. Steps being taken and progress made to take advantage of present opportunity United States has of developing internationally.

SAFETY ENGINEERING

Boiler Rooms

Boiler Room Rules. Eng. & Cement World, vol. 13, no. 10, Nov. 15, 1918, p. 66. Suggestions to boiler-room attendants on the care of oilers and prevention of accidents. From Safety Bul.

Boiler Shops

Accident Prevention in Boiler Shops. Boiler Maker, vol. 18, no. 11, Nov. 1918, pp. 315-317, 5 figs. Account of what Bethlehem Steel Co. has accomplished and consideration of causes of accidents.

Disease Prevention

Engineers and Disease Prevention. Times Eng. Supp., no. 529, Nov. 1918, p. 231. Points out part engineers can play.

First Aid

Standardization of First Aid Methods, C. H. Connor. Safety Eng., vol. 36, no. 4, Oct. 1918, pp. 237-238. From Proc. Seventh Annual Safety Congress.

Foundries

Injuries from Molten Metal, Chesla C. Sherlock. Iron Age, vol. 102, no. 21, Nov. 21, 1918, pp. 1262-1262. Ordinary perils; defective tools and appliances; basis of foundryman's responsibility.

Water-Supply Protection

Protection of Water Mains, Fire Hydrants and Valves in Winnipeg, Thomas H. Hooper. Mun. Jl., vol. 45, no. 21, Nov. 23, 1918, p. 410. From Quarterly of Nat. Fire Protection Assn.

Woodworking Industry

Infections and Blood Poisoning in the Woodworking Industry, Leroy Philip Kuhn. Safety Eng., vol. 36, no. 4, Oct. 1918, pp. 228-230. From Proc. Seventh Annual Safety Congress.

SALVAGE

Salvaging and Utilizing Wastes and Scrap in Industry, W. Rockwood Conover. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 449-451. Significance of salvaging; reclaiming practice for number of classes of materials and wastes.

TRANSPORTATION

Comparative Methods

Light-Traffic Railway vs. Highway and Motor Truck, Clement C. Williams. Eng. News-Rec., vol. 81, no. 22, Nov. 28, 1918, pp. 984-985. Analyses of operating expenses, fixed charges and amount and kind of traffic should be made for each case.

Motor Trucks

Highway-Motor Truck Problem as Viewed by User, Manufacturer and Engineer. Eng. News-Rec., vol. 81, no. 22, Nov. 28, 1918, pp. 968-977, 2 figs. Three views. Limitations to be Placed on Trucks, from User's Viewpoint, by George H. Pride; Factors that Will Govern Future Road Design, by Edward L. Viets; Highways and Truck Loads they Can Economically Sustain, by H. Eltinge Breed.

Motor Truck Transportation Growing Rapidly. Ry. Rev., vol. 63, no. 22, Nov. 30, 1918, pp. 763-769, 11 figs. Formerly regarded as competitive, inter-city motor-truck traffic is now encouraged by railroads.

Industrial Technology

Alcohol

Industrial Alcohol. Times Eng. Supp., no. 529, Nov. 1918, p. 228. Possible sources of supply.

Asphalt

Chemical Constitution of Artificial Asphalts (La constitution chimique des asphaltes artificiels). Génie Civil, vol. 73, no. 13, Sept. 28, 1918, p. 256. Results of experiments with petroleum residues, lignite, tars and schist. From Zeitschrift fur angewandte Chemie, June 11 and 18.

Coal Distillation

Distillation at Low Temperature. Gas Age, vol. 42, no. 11, Dec. 2, 1918, pp. 466-467. Discusses advantages of "coalite" process. From Journal des Usines a Gaz.

Low Thermal Distillation of Coals, G. W. Traer. Coal Industry, vol. 1, no. 10, Oct. 1918, pp. 393-395. Details of experimental plant; characteristics of semi-coke or charcoal; how to make a coke of suitable structure. Am. Inst. Min. Engrs. paper.

Dust Precipitation

Electrostatic Dust Precipitation, William H. Easton. Indus. Management, vol. 56, no. 6, Dec. 1918, pp. 473-475, 5 figs. Dust-laden gases become ionized when passing through field around grounded tubes inside which fine wires are charged with current at 50,000 to 100,000 volts.

Gas Manufacture

Coal Conservation in Relation to Gas Manufacture, Tim Duxbury. Gas Jl., vol. 144, no. 2895, Nov. 5, 1918, pp. 302-305 and (discussion) pp. 305-308. Results of experience with vertical retorts. Paper before Manchester Instn. of Gas Engrs. Also in Gas World, vol. 69, no. 1789, Nov. 2, 1918, pp. 262-263, 1 fig.

Economizing Coal in Gas Manufacture, Frederick Shewring. Gas World, vol. 69, no. 1789, Nov. 2, 1918, p. 261. Comments on steaming retorts.

Inclined Retort Plant at Rome, N. Y., A Success, S. Bent. Russell. Gas Age, vol. 42, no. 11, Dec. 2, 1918, pp. 463-466, 4 figs. Views and mechanism details of plant having daily capacity of 500,000 cu. ft. of gas.

Institution of Gas Engineers. Gas Investigation Committee. Gas Jl., vol. 144, nos. 2894 and 2895, Oct. 29 and Nov. 5, 1918, pp. 235-249, 3 figs. and (discussion) pp. 291-299. Report of sub-committee appointed to investigate relative efficiency in use of different grades and compositions of gas.

Glass

Substitutes for Glass. Sci. Am. Supp., vol. 86, no. 2235, Nov. 2, 1918, p. 283. Composition of siloxide and artificial mica; possibilities of derivatives of cellulose, oiled cotton cloth and vitro-cellulose. From La Nature.

Leather

Recent Developments in Leather Chemistry, Henry R. Proctor. Jl. Roy. Soc. of Arts, vol. 66, no. 3442, Nov. 8, 1918, pp. 776-781. Discussion of chemical and physical changes taking place in tanning process.

Naphthalene and Benzol

Estimation of Naphthalene in Coal Gas, Harold G. Colman. Gas Jl., vol. 144, no. 2894, Oct. 29, 1918, pp. 231-232. Modifications in Colman-Smith's method (vol. 75, p. 798.)

Notes on Benzol and Naphthalene Recovery, Harold E. Copp. Gas Jl., vol. 144, no. 2895, Nov. 5, 1918, pp. 311-313, 2 figs. Results obtained with plant installed at gas works. Paper before Midland Assn. of Gas Engrs. and Mgrs. Also in Gas World, vol. 69, no. 1789, Nov. 2, 1918, pp. 265-266.

Nitric Acid

Nitric Acid as a By-Product of Internal Combustion Engines, A. W. H. Griepe. Am. Gas Eng. Jl., vol. 109, no. 21, Nov. 23, 1918, pp. 487-489, 7 figs. and p. 492. Process to precipitate nitric oxide as by-product of internal-combustion engines, flue gases, illuminating gas, furnace gas, blast-furnace gas, natural gas, etc.

Oxygen and Hydrogen

Electrolytic Oxygen and Hydrogen. Travelers' Standard, vol. 6, no. 7, July 1918, pp. 137-145. Method of producing oxygen and hydrogen and their respective industrial applications.

Potash

Recovery of Potash from Blast Furnaces, Linn Bradley. Iron Age, vol. 102, no. 19, Nov. 7, 1918, pp. 1151-1153. From paper before Fourth Nat. Expos. of Chem. Ind., New York, September 1918.

Stoneware

Chemical Stoneware, Fred A. Whitaker. Brick & Clay Rec., vol. 53, no. 11, Nov. 19, 1918, pp. 875-877, 10 figs. Account of development of industry in United States.

Water Gas

Applications of Peat for the Production of Water Gas (Tyrs Anvendelse til Fremstilling af Vandagas). Ingenioren, year 27, no. 86, Oct. 26, 1918, pp. 561-562.

Railroad Engineering

BRITISH

British Railways

British Railways Under War Conditions. Engineer, vol. 126, no. 3280, Nov. 8, 1918, pp. 390-391. What they cost the country. Eighth article.

ELECTRIC RAILROADS

(Not including Street and Interurban Lines)

Argentine Railways

Electric Traction on the Central Argentine Railway. Ry. Gaz., vol. 29, no. 18, Nov. 1, 1918, pp. 466-469, 4 figs. Cables; substations. (Continuation of serial.) Also in Engineer, vol. 126, no. 3279, Nov. 1, 1918, pp. 367-370, 12 figs.

Energy Consumption

Energy Consumption of Cars Is Affected by Temperature Changes, M. B. Rosevear. Elec. Ry. Jl., vol. 52, no. 22, Nov. 30, 1918, pp. 958-960, 2 figs. That power required for car operation is affected by variations in schedule speed, number of passengers carried and temperature is shown by extended study made by Public Service Railway, Newark, N. J.

Substations

Automatic Substations and Direct-Current Railway Systems (Les sous-stations automatiques et les réseaux de traction à courant continu). Revue Générale de l'Electricité, vol. 4, no. 11, Sept. 14, 1918, pp. 386-392, 7 figs. Details of operation; scheme of connections for 600-volt systems; tables of results obtained in actual installations.

See also ELECTRICAL ENGINEERING, Transformers (Substations).

ELECTRIFICATION

Montreal Tunnel

Montreal Tunnel Zone Electrification, William G. Gordon. Elec. Ry. Jl., vol. 52, no. 22, Nov. 30, 1918, pp. 962-965, 5 figs. Summary of details of rolling stock, overhead and substation equipment; design and construction problems. Abstract of paper before Am. Inst. of Elec. Engrs., Toronto, Nov. 1918.

EQUIPMENT

Ditcher

Electrically Operated Ditcher Effects Big Saving, Charles W. Ford. Elec. Ry. Jl., vol. 52, no. 22, Nov. 30, 1918, pp. 960-961, 5 figs. This is first electric machine built for ditching purposes; operates at 1200 or 1500 volts with 30-hp. motor.

LABOR

British Railways

British Railways Under War Conditions. Engineer, vol. 126, no. 3279, Nov. 1, 1918, pp. 371-372. Railwaymen's war bonus. Seventh article.

MAINTENANCE

Maintenance of Way Records and Reports. Ry. Rev., vol. 63, no. 19, Nov. 9, 1918, pp. 667-668. Methods being worked out by Railroad Administration for establishing accurate records; will standardize reports.

Pacific Electric's New Car Storage and Repair Facilities, Clifford A. Elliott. Elec. Ry. Jl., vol. 52, no. 21, Nov. 23, 1918, pp. 914-917, 11 figs. Description of three divisional storage track layouts with car houses and repair shops.

LOCOMOTIVES

Boiler for Mallet Locomotive

Large Boiler for New Mallet Locomotive. Boiler Maker, vol. 18, no. 11, Nov. 1918, pp. 303-304, 4 figs. Sections and elevations of boiler built for heavy grades, having firebox length of 181 1-16 in. and designed for 215-lb. working pressure.

Feedwater Heating

Locomotive Feed Water Heating, H. S. Vincent. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, serial 1st part, pp. 645-649, 8 figs. Discussion of exhaust steam and waste gas methods of preheating.

French Compound

Recent Locomotives for the French State Railways, F. C. Coleman. Ry. Age, vol. 65, no. 20, Nov. 15, 1918, pp. 861-863, 4 figs. Principal data and descriptions of four-cylinder compound pacific type and simple consolidation type built in Great Britain.

Rock Island Heavy

2-10-2 Type Locomotive for the Rock Island Lines. Ry. Age, vol. 65, no. 23, Dec. 6, 1918, pp. 992-994, 6 figs. Novel and interesting features.

Santa Fe Heavy

A. T. & S. F. 4-8-2 Type of Locomotives. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, pp. 649-652, 3 figs. Heaviest of type yet built. Principal dimensions and data.

Santa Fe Passenger

Mountain Type Locomotive for the Santa Fe. Ry. Rev., vol. 63, no. 20, Nov. 16, 1918, pp. 697-698, 3 figs. Description and principal data of heavy fast passenger locomotive. Also in Ry. Age, vol. 65, no. 22, Nov. 29, 1918, pp. 957-959, 1 fig.

Standard

Data for Standard Locomotives. Ry. Mech. Eng., vol. 92, no. 11, Nov. 1918, pp. 607-610, 12 figs. Tonnage rating charts and clearance and weight diagrams for government locomotives now built.

Standard Switcher

Standard Six-Wheel Switcher. Ry. Mech. Eng., vol. 92, no. 11, Nov. 1918, pp. 593-596, 5 figs. Principal data and description with drawings.

Superheating

Superheater Locomotive Performance. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, pp. 652-655, 1 fig. Abstract of committee report presented at the 1918 Convention of the Traveling Engrs. Assn., with discussion.

Virginian Heavy Grade Pusher

Virginian 2-10-10-2 Locomotives. Ry. Mech. Eng., vol. 92, no. 11, Nov. 1918, pp. 600-604, 6 figs. Principal data and description with drawings. Built for heavy grade pusher service.

NEW CONSTRUCTION

American-Built Railroad Cutoff will Relieve Traffic Congestion in France, Robert K. Tomlin, Jr. Eng. News-Rec., vol. 81, no. 19, Nov. 7, 1918, pp. 832-835, 14 figs. A 5¾-mile double-track line for Expeditionary forces; big embankment chief feature; bridge half a mile long.

OPERATION AND MANAGEMENT

British Operation

Presidential Address to the Institution of Civil Engineers, John A. F. Aspinall. Ry. Gaz., vol. 29, no. 19, Nov. 8, 1918, pp. 487-494. British railway engineering and operation; immediate problems to be faced.

Fuel Conservation

Conservation of Fuel on the Railroads. Ry. Age, vol. 65, no. 21, Nov. 22, 1918, pp. 913-916. Abstracts of papers presented by railway men before New York Ry. Club.

Work of the Fuel Conservation Section, E. C. Schmidt. Ry. Rev., vol. 63, no. 22, Nov. 30, 1918, pp. 769-772. Organization and work of this department of Railroad Administration.

Supervision of Locomotives, British

District Supervision of Locomotives on British Railways, W. Patterson. Ry. Gaz., vol. 29, no. 18, Nov. 1, 1918, pp. 469-471. Review of work in a typical district with a staff of about 500 persons and sheds to which are allotted 150 engines.

Traffic Control

Controlling the Freight Traffic, North-Eastern Railway. Engineer, vol. 126, no. 3276, Oct. 11, 1918, pp. 305-306, 3 figs. Description of traffic control of North-Eastern Railway, and control board.

See also CIVIL ENGINEERING, Water Supply.

PERMANENT WAY AND BUILDINGS

Floor Slabs and Culverts

Railway Practice in Design of Concrete Floor Slabs and Flat Top Culverts. Eng. & Contracting, vol. 50, no. 21, Nov. 20, 1918, pp. 511-512. Results of questionnaire by George H. Tinker. From Oct. Bulletin of Am. Ry. Eng. Assn.

Relocation of Lines

New York Central Relocates Lines to Cross Barge Canal at the Tonawandas. Eng. News-Rec., vol. 81, no. 20, Nov. 14, 1918, pp. 893-896, 2 figs. Detour two miles long around hearts of cities at once combines bridges over waterway and solves difficult problem of eliminating grade crossings and occupation of main business streets.

See also CIVIL ENGINEERING, Bridges, Building and Construction.

RAILS

Transverse Fissures

Transverse Fissures and Phosphorus Streaks in Rails, G. F. Comstock. Ry. Age, vol. 65, no. 22, Nov. 29, 1918, pp. 961-963, 2 figs. New evidence of influence of segregation and of advantage of reheating blooms. Abstract of paper before Am. Inst. of Min. Engrs.

Transverse Fissures Cause Rail Failures. Ry. Age, vol. 65, no. 23, Dec. 6, 1918, pp. 1007-1009. Abstract of James E. Howard's report of the rail failure at Central Islip, N. Y.

ROLLING STOCK

Cleaning

Passenger Car Cleaning on the Canadian Pacific Railway, E. Eley. Can. Ry. Club, vol. 17, no. 6, Sept. 1918, pp. 19-22, and (discussion) pp. 23-31. Nature and amount of work required by different classes of cars.

Coal Cars

Design of Seventy-Ton Coal Car with Tandem Hoppers. Ry. Mech. Eng., vol. 92, no. 11, Nov. 1918, pp. 611-613, 5 figs. Principal data with description and drawings.

Flat Cars

Shipping Large Marine Boilers. Boiler Maker, vol. 18, no. 11, Nov. 1918, p. 307, 1 fig. Describes special flat car for shipping Scotch boilers. From Marine Jl.

Lighting

Standards of Passenger Car Lighting. Ry. Rev., vol. 63, no. 19, Nov. 9, 1918, pp. 672-673. Specifications prepared by mechanical department of United States Railroad Administration for electric lighting of passenger equipment cars hereafter to be purchased by administration for use of roads under its control.

Refrigerator Cars

Standard U. S R. A. Refrigerator. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, pp. 663-668, 7 figs. Latest practices in design. Also in Ry Age, vol. 65, no. 21, Nov. 22, 1918, pp. 906-910, 4 figs.

SAFETY AND SIGNALING SYSTEMS

Coupling and Uncoupling

Prevention of Accidents Due to Coupling and Uncoupling Cars. E. M. Switzer. Safety Eng., vol. 36, no. 4, Oct. 1918, pp. 262-264. From Proc. Seventh Annual Safety Congress.

Interlocking

Single Line Interlocking on the New South Wales Railways. Ry. Gaz., vol. 29, no. 19, Nov. 8, 1918, pp. 495-497, 4 figs. Outline of system of interlocking and signalling line stations.

Plant Railroad Hazards

Plant Railroad Hazards, C. H. Baltzell. Safety Eng., vol. 36, no. 4, Oct. 1918, pp. 252-256, 2 figs. Possibilities of personal injuries in plants situated on main line tracks and manner of avoiding them. From Proc. Seventh Annual Safety Congress.

Signaling

Proceedings, Annual Meeting, New York, N. Y., Sept. 19-20, 1918, Ry. Signal Assn., Jl. 23d year. No. 4, Dec. 1918, pp. 313-420, 4 figs. Addresses, committee reports, etc.

SHOPS

Boiler-Tube Fitting

Modern Locomotive Boiler Tube Practice at Doncaster Works, Great Northern Railway. Ry. Gaz., vol. 29, no. 19, Nov. 8, 1918, pp. 499-500, 4 figs. Methods employed for fitting and expanding boiler tubes and superheater flues.

Car Repairs

Car Department of the Milwaukee. Ry. Mech. Eng., vol. 92, no. 11, Nov. 1918, pp. 615-620, 9 figs. Organization and methods of handling light and heavy car repairs with samples of forms used.

Grinding

Grinding in Locomotive Shops, M. H. Williams. Ry. Mech. Eng., vol. 92, no. 11, Nov. 1918, pp. 629-632, 4 figs. Uses to which internal, cylindrical and surface grinding machines may be put with success.

Locomotive Repairs

Accuracy in Locomotive Repairs, M. H. Williams. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, pp. 673-677, 8 figs. Methods of making and fitting repair parts for locomotives with gages and micrometers.

Repair Shops

American Railroad Repair Shops in France, Robert K. Tomlin, Jr. Am. Mach., vol. 49, no. 21, Nov. 21, pp. 933-938, 7 figs. How these shops were built by American engineers in France.

SPECIAL LINES

Logging Roads

Soldiers Build Logging Roads in Spruce Forests, W. A. Welch. Ry. Age, vol. 65, no. 19, Nov. 8, 1918, pp. 805-807, 6 figs. Description of construction of over 350 miles of new railway in Northwest for carrying airplane lumber to mills.

See also CIVIL ENGINEERING, Harbors.

Munitions and Military Engineering

Ballistics

A Field Ballistic Problem, Meade Wildrick. Jl. U. S. Artillery, vol. 49, no. 3, May-Aug. 1918, pp. 159-186, 9 figs. Numerical illustration of (1) construction of range table, (2) construction of range correction curves, (3) construction of deflection correction chart, (4) correction for variation in muzzle velocity due to a variation in weight of projectile, and (5) correction for variation in temperature of powdered charge.

Effect of the Earth's Rotation Upon the Point of Fall, Fred M. Green and C. W. Green. Jl. U. S. Artillery, vol. 49, no. 3, May-Aug. 1918, pp. 192-204, 10 figs. Derives, from consideration of effect of difference in velocity of gun and target due to earth's rotation, approximate expressions for corrections required in trajectory of projectile fired at long range.

Notes on Inclined Trajectories, F. M. Green and C. W. Green. Jl. U. S. Artillery, vol. 49, no. 3, May-Aug. 1918, pp. 187-191, 1 fig. Suggest manner of constructing table of discrepancies between results obtained by Ingalls' formula and by simplified form $\Phi = \Phi_x + \epsilon$ where Φ is the quadrantal angle of departure, Φ_x the range table angle of departure to attain range, and ϵ angle of elevation of target.

Simpson's Resection, Stanley H. Simpson. Jl. U. S. Artillery, vol. 49, no. 3, May-Aug. 1918, pp. 208-214, 3 figs. Explains method in which, angles being measured in mils, instead of plotting actual arcs, short chords of these arcs are plotted on a scale large enough to make chords practically coincident with arcs.

The Elliptic Trajectory Over the Earth, G. Greenhill. Engineering, vol. 106, no. 2754, Oct. 11, 1918. A mathematical article.

Bullets

Explosive, Expansive and Perforating Bullets, Claude Pernelle. Sci. Am. Supp., vol. 86, no. 2238, Nov. 23, 1918, pp. 332-333, 5 figs. Types used by German and Austrian armies. Translated from La Nature.

Howitzers

How the 155-Mm. Howitzer is Made, J. V. Hunter. Am. Mach., vol. 49, nos. 21 and 22, Nov. 21 and 28, 1918, pp. 941-945, 17 figs., and 983-986, 14 figs. Work on howitzer jacket after it has been rough-machined and heat-treated. Nov. 28: Making the tube.

Mobile Batteries

Railroad Men Man Mobile Battery for Navy. Ry. Age, vol. 65, no. 22, Nov. 29, 1918, pp. 967-969, 4 figs. Description of 14-inch naval guns on railway mounts which worked destruction behind German lines.

Ordnance Manufacture

Finding the "Choke Points" of Ordnance, John H. Van Deventer. Am. Mach., vol. 49, no. 22, Nov. 28, 1918, pp. 967-971, 6 figs. One of series of articles on work of Ordnance Dept.

Munitions Production by British Railways. Ry. Rev., vol. 63, no. 19, Nov. 9, 1918, pp. 671-672. Account of reorganization of railway shops in Great Britain to become one of England's chief sources of supply for munitions of war. Adapted from Board of Trade Journal, London.

The Manufacture of Guns (La fabrication des canons), Ch. Dantin. Génie Civil, vol. 73, no. 1875, July 20, 1918, pp. 41-47, 21 figs. Considerations governing choice of metal and description of manufacturing process.

What Ordnance Is and Does, John H. Van Deventer. Am. Mach., vol. 49, no. 20, Nov. 14, 1918, pp. 876-881, 7 figs. Organization of Ordnance Department and what it does. First article.

Ordnance Plant

A War-Time American Ordnance Plant. Iron Age, vol. 102, no. 22, Nov. 28, 1918, pp. 1326-1328, 5 figs. Description of new plant of Tacony Ordnance Corporation.

Shells

The Manufacture of Semi-Steel Shells. Iron Age, vol. 102, no. 22, Nov. 28, 1918, pp. 1317-1321, 32 figs. Practice as recommended by Ordnance Department; chemical, metallurgical, molding and machining details.

Spotting Board

Spotting Board, G. R. Meyer. Jl. U. S. Artillery, vol. 49, no. 3, May-Aug. 1918, pp. 205-207, 1 fig. Constructed to furnish battery commander with information as to longitudinal deviation of his shots.

See also MECHANICAL ENGINEERING, Foundries (Semi-Steel).

General Science

CHEMISTRY

Electrolytic Conductivity

Electrolytic Conductivity in Non-Aqueous Solutions. II. The Electrical Conductance of Trimethyl-Para-Tolyl-Ammonium Iodide in Water and Several Organic Solvents, Henry Jermain, Maude Creighton and D. Herbert Way. Franklin Inst. Jl., vol. 186, no. 6, Dec. 1918, pp. 675-698, 7 figs. Investigations.

Elements

Atomic Number and Frequency Differences in Spectral Series, Herbert Bell. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 214, Oct. 1918, pp. 337-347, 2 figs. Numerical tests of Rydberg's law that square root of doublet and triplet differences is proportional to atomic weights, substituting atomic number for atomic weight.

Elements in the Order of Their Atomic Weights, Raymond Szymanowitz. Chem. News, vol. 117, no. 3059, Oct. 25, 1918, pp. 339-340. Presents table which shows numbers follow scheme of sequence expressed by: X, $X + 3$, $X + 3 + 1$, $X + 3 + 1 + 3$, etc., adding 1 and 3 alternately.

Solutions

The Electrical Conductivity of Acids and Bases in Aqueous Solutions, Jnanendra Chandra Ghosh. Jl. of the Chem. Soc., vols. 113-114, no. 672, Oct. 1918, pp. 790-799. Explains abnormally high mobility of hydrogen and hydroxyl-ions in aqueous solutions on assumption that electricity is partly carried by ordinary process of convection and partly propagated through water molecules undergoing alternate dissociation and recombination; apparently high activity of strong acids and bases is also traced to this cause; modifies Ostwald equation for electrolytes where degree of dissociation is less than one.

Structure of Matter

Atomic Structure from the Physico-Chemical Standpoint, Alfred W. Stewart. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 214, Oct. 1918, pp. 326-336, 1 fig. Model atom proposed as having a structure accounting for all the facts known concerning elements, including radioactive transformations.

Interfacial Tension and Complex Molecules, G. N. Antonoff. Lond. Edinburgh & Dublin, Phil. Mag., vol. 36, no. 215, Nov. 1918, pp. 377-396, 5 figs. Theory of molecular attraction based on modern representation of nature

of atoms and molecules; explanation of phenomena of molecular attraction by action of forces which cause chemical affinity; deduction of relation between surface tension and molecular pressure.

Valency

Definition of Valency. F. H. Loring. Chem. News. vol. 117, no. 3058, Oct. 11, 1918, pp. 319-322. Simile to explain significance of term and nature of atoms which exercise variable valencies.

MATHEMATICS

Analytical Functions

Factoring and Prolongation of Analytical Functions (Quelques remarques sur la décomposition en facteurs primaires et le prolongement des fonctions analytiques), Emile Picard. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 12, Sept. 16, 1918, pp. 405-408. Further comment on Weierstrass' method of decomposition. In Comptes-rendus, vol. 92, 1881, p. 690, author showed application of this method to uniform functions whose roots approach indefinitely a given line.

Conics

Involutions on the Rational Cubic. R. M. Winger. Bul. Am. Math. Soc., vol. 25, no. 1, Oct. 1918, pp. 27-34. Establishes that lines joining pairs of contacts of tangents from points of R^2 envelop conic N which touches nodal tangents (where they meet line of flexes) and has contacts with R^3 at sextactic points; also other theorems in regard to properties of hyperosculating curves of R.

Divergent Series

A Conspectus of the Modern Theory of Divergent Series. Walter B. Ford. Bul. Am. Math. Soc., vol. 25, no. 1, Oct. 1918, pp. 1-15. Review of modern theory of divergent series in regard to (1) the question as to how a sum may be assigned to a divergent series in general, and (2) the functional properties of asymptotic series; proposed limitations to form a consistent general theory of summation.

Equations

A Determinantal Equation Whose Roots are the Products of the Roots of Given Equations, William H. Metzler. Proc. Roy. Soc. of Edinburgh, vol. 38, part 1, session 1917-1918, pp. 57-60. By multiplying one by one successive equations from k linear homogeneous sets (1), (2), ... (k) in $n_1, n_2, \ldots n_k$ variables a new set is formed. The new set will contain $n = n_1 . n_2 \ldots\ldots n_k$ equations in same number of variables and its determinant when equated to zero is the proposed determinantal.

Simultaneous Linear Differential Equations Involving Partial Derivatives and Reduction of Hyper-Geometric Functions of Two Variables (Sur des équations linéares simultanées aux dérivées partielles et sur des cas de réduction des fonctions hyper-géométriques de deux variables), Paul Appell. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 12, Sept. 16, 1918, pp. 408-413.

Solution of Partial-Derivative Equations by Means of Hermite's Polynomials (Sur les équations aux dérivées partielles vérifiées par les polynomes d'Hermite, déduits d'une exponentielle), Pierre Humbert. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 15, Oct. 7, 1918, pp. 522-525. Application of Appell's method (Comptes rendus, vol. 167, 1918, p. 309) to variables obtained from differentiation of exponential function whose exponent is of quadratic form in X and Y.

Solutions of Differential Equations as Functions of the Constants of Integration, Gilbert Ames Bliss. Bul. Am. Math. Soc., vol. 25, no. 1, Oct. 1918, pp. 15-26. Proposes method.

Treatment of Partial-Derivative equations by Hyperspherical Polynomials (Sur les systèmes d'équations aux dérivées partielles vérifiés par les polynômes hypersphériques), J. Kampé de Fériet. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 15, Oct. 7, 1918, pp. 519-522. Study of case of n linear equations involving partial derivatives of second order.

Fourier Series

On the Cesàro Convergence of Restricted Fourier Series, W. H. Young. Proc. Roy. Soc., vol. 95, no. A665, Sept. 2, 1918, pp. 22-29. Establishes from operations on trigonometric series Σ (a_r cos r X + b_r sin r X) that Legendre series converges (C ½) almost everywhere in interval ($0 < X < 1$), and that it converges (C ½) at every internal point X of this interval at which f (X) is continuous, or is the differential coefficient of its integral, or satisfies some other condition sufficient to insure convergence (CK), for same value of K > ½, of Fourier series of a function equal to f (cos θ) in a small interval containing point Z considered ($X = \cos\theta$ ($0 < X < 1$).

Invariants

Related Invariants of Two Rational Sextics, J. E. Rowe. Bul. Am. Math. Soc., vol. 25, no. 1, Oct. 1918, pp. 34-35 Points out relation between invariants of the R^6_2 and invariants of the R^6_2.

Isogenous Complex Functions

Note in Isogenous Complex Functions of Curves. W. C. Graustein. Bul. Am. Math. Soc., vol. 24, no. 10, July 1918, pp. 473-477. Derivation of theorem: if gradients c_1, c_2 of functions F_1, F_2 in $F = F_1 + i\,F_2$ where $F_1 = F_1 \,|[L]|$, $F_2 = F_2 \,|[L]|$ are first-degree functions of space curve L, are in general analytic, then the gradients γ_1, γ_2 of Φ_1, Φ_2 in $\Phi = \Phi_1 + i\,\Phi_2$, an arbitrary complex function of L of the first degree isogenous to F, are analytic save in points of singularity of c_1 or c_2 and points in which these vectors are indeterminate. $F\,|[L]|$ represents a function of L such that $F\,|[-L]| = -F\,|[L]|$.

Orthogonal Substitution

Note on the Construction of an Orthogonant. Thomas Muir. Proc. Roy. Soc. of Edinburgh, vol. 38, part 2, session 1917-1918, pp. 146-153. Comments of and addition of theorems to Cayley's mode of forming an orthogonal substitution.

Polynomials

A Reduction Formula for the Functions of the Second Kind Connected with the Polynomials of Applied Mathematics, Pierre Humbert. Proc. Roy. Soc. of Edinburgh, vol. 38, part 1, session 1917-1918, pp. 61-69. Method by which a polynomial B_n (Z) of degree $n-1$ satisfying certain conditions is introduced in practical computations involving Legendre's functions in order to reduce them to a form $f_{n-1}(z) = [z\,P_n\,(z) - B_n\,(z)]\,(z^2-1)$; application of this method to Lamé's functions, to extended Legendre's polynomials and to parabolic-cylinder function when n is an integer.

Probability

An Elementary Derivation of the Probability Function, Albert A. Bennett. Bul. Am. Math. Soc., vol. 24, no. 10, July 1918, pp. 477-481. Derives by means of elementary considerations equation of probability from sequence of binomial coefficients.

PHYSICS

Flame Propagation

The Propagation of Flame through Tubes of Small Diameter. William Payman and Richard Vernon Wheeler. Jl. Chem. Soc., vols. 113 & 114, no. 670, Aug. 1918, pp. 656-666, 3 figs. Report of experiments, performed in connection with work on construction of miners' safety lamp, on speed of uniform movement during propagation of flame in mixtures of methane and air through tubes of small diameter, on the passage of flame through similar tubes filled with mixtures of methane and air and open at both ends, and on the passage or projection of flame through short tubes of small diameter.

Fluorescence

On the Phenomena of Fluorescence, Desmond Geoghegan. Chem. News, vol. 117, no. 3058, Oct. 11, 1918, p. 322. Suggests experiment which, it is said, will prove that rays of light passed through a sufficient thickness of a fluorescent substance lose thereby power of exciting fluorescence when they are passed through a second layer of same substance.

Magneto-Thermal Phenomena

Magneto-thermal Phenomena (Le phénomène magnétocalorique), Pierre Weiss and Auguste Piccard. Journal de Physique, vol. 7, May-June 1917, pp. 103-109, 1 fig. Account of pronounced changes in temperature which were observed in course of experimental measurements preliminary to plotting set of isothermals for nickel. Near Curie's point temperature increased 0.7 deg. on establishing field of 15,000 gausses.

Optics

The Correction of Telescopic Objectives, T. Smith. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 215, Nov. 1918, pp. 405-412. Criticism of expressions for constructional data for small objectives as given by A. O. Allen in Phil. Mag. June 1918.

The Scattering of Light by Air Molecules, R. J. Strutt. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 214, Oct. 1918, pp. 320-321. Supplements former account of experiments (Proc. Roy. Soc. A., vol. 44, p. 453, 1918) by answering inquiry from R. W. Wood (Phil. Mag., vol. 36, p. 272, Sept. 1918) in regard to precautions taken for drying air in experiments.

Quanta Law

Researches on the Limit of the Continuous Spectrum of X-Rays (Recherches sur la limite du spectra continu des rayons X), Alex. Muller. Archives des Sciences Physiques et Naturelles, year 123, vol. 46, Aug. 1918, pp. 63-73, 1 fig. Theoretical and experimental vertification of Planck's law of quanta as generalized by Einstein by confirming the relation $e\,V = h\,\nu$ in the case of the continuous spectrum of X-rays, and for an interval from 14 to 28 kilovolts.

Radium

On Some Properties of the Active Deposit of Radium, S. Ratner. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 215, Nov. 1918, pp. 397-405, 2 figs. Experimental research which leads author to question whether phenomenon of recoil of RaC from RaB has ever been observed, also that proportion of recoil atoms of RaB carrying negative charge is less than 1 to 100,000.

Relativity

On the Essence of Physical Relativity, Joseph Larmor. Proc. Nat. Academy of Sci., vol. 4, no. 11, Nov. 1918, pp. 334-337. Offers objection to Leigh Page's expression (no. 4, p. 46) for translatory force required to sustain assigned varying velocity in electrostatic system of type usually investigated as model of electron.

Semi-Fluids

Mechanics of Semi-Fluids (Mécanique des semi-fluides). Comptes Rendus des Séances de l'Académie des Sciences, vol. 167, no. 7, Aug. 12, 1918, pp. 253-256. Discusses possibility of disregarding tangential action of central cylinder on annular part of the limiting surfaces.

Vibrations and Wave Motions

Diffraction of Plane Waves by a Screen Bounded by a Straight Edge, F. J. W. Whipple. Lond. Edinburgh & Dublin Phil. Mag., vol. 36, no. 215, Nov. 1918, pp. 420-424. Adaptation of R. Hargreaves' method for simple harmonic wave (Phil. Mag., vol. 36, p. 191), to diffraction of waves of arbitrary type.

Periodic Irrotational Waves of Finite Height, T. H. Havelock. Proc. Roy. Soc., vol. 95, no. A665, Sept. 2, 1918, pp. 38-51. Extension of Mitchell's form for highest wave and its generalization by means of surface conditions; method of approximation for coefficient; calculation for highest wave; values when $e^{-d} = ¾$; comparison with Stokes' series; determination of b^1; numerical examples and remarks upon coefficients.

The Interferometry of Vibrating Systems. C. Barus. Proc. Nat. Academy of Sci., vol. 4, no. 11, Nov. 1918, pp. 328-333, 4 figs. Report of experimental work.

The Sound Waves and Other Air Waves of the East London Explosion of January 19, 1917, Charles Davison. Proc. Roy. Soc. of Edinburgh, vol. 38, part 2, session 1917-1918, pp. 115-129, 1 fig. Construction of paths followed by air waves and sound waves; offered explanation for fact that inaudible air waves were observed beyond limits of sound areas by reason of their more nearly horizontal path.

OPTICAL PROJECTION FOR SCREW-THREAD INSPECTION

Analysis of Screw-Thread Elements Essential to Strength and Dependability—Description of a New and Improved Method for Their Accurate Inspection

By JAMES HARTNESS,[1] SPRINGFIELD, VT.

THE screw, one of the most important elements in mechanism and found in nearly all forms of machinery, is invaluable as a means for fastening two parts together, as a means of precision adjustment, and as a means of transmitting power.

In machines in which the weight must be kept as low as possible, as, for instance, in the airplane, it is of prime importance to have the screw as small as consistent with the strength and reliability required.

On account of the vagueness of our general knowledge of the conditions under which it takes its stress, we frequently underestimate the importance of the screw, and, through ignorance, continue practices that greatly increase the hazard of life in travel by rail, automobile or airplane, as well as lessen the reliability of performance of other pieces of machinery. A screw-thread fastening is very dependable if the two component parts are properly fitted.

While it is not possible to attain perfection in this work, an analysis of the various elements that are essential for strength and dependability, and the reduction of weight, will greatly simplify our efforts and make it possible to attain a point much nearer perfection.

Briefly stated, a screw's reliability depends upon the following elements:

a Material
b Form of profile of the thread
c Diameter of the screw
d Lead or the number of threads per inch.

After the foregoing general characteristics have been determined, we must consider the following details which depend on the methods and skill employed in production:

1 Smoothness and density of surface
2 Fit, which relates particularly to the exact relationship of the size of the two component parts
3 Precision of lead, which relates to the precision of advance of the helix or degree of precision with which the number of threads per inch are made
4 Uniformity or steadiness of advance of helix
5 Form, relating to contour of a single thread
6 Roundness, as relating to the circular path of the helix
7 Parallelism or taper.

These elements are all interrelated.

Modern practice in constructing machinery is drifting more and more toward absolute interchangeability of parts. In the older practice it was customary to fit one part to another, either by doing the final finishing at the time the parts were assembled or by selective process, such as picking out the larger screws to be used with the larger nuts or tapped holes and smaller screws to be used with smaller holes.

To a certain degree this method of fitting at the time of assembling, either by changing the sizes of the parts that go together or by selective process, is still necessary in the highest requirements of very close fits, but the trend is strongly toward perfect interchangeability.

This requires working to stated standards so that the size of the thread of the screw and nut will never exceed certain boundaries. But whether the boundary allows no freedom when the largest screw is turned into the smallest nut or a certain predetermined freedom of play, there still remains the necessity for determining how large an internal thread may be made and still be acceptable, and how small the screw may be made and still be acceptable; in other words, what is the greatest degree of looseness that can be tolerated without impairing the dependability of the screw and nut for service.

Thus far we have had no satisfactory way of specifying all of the elements that are required to make a screw dependable, but we are now finding that the projection lantern offers a better method and makes it possible to simplify specification and practice.

The Fit of Screws in Relation to Their Diameter

It will be understood that the largest percentage of screws must be made with sufficient play to make it possible to screw them together rapidly by hand, and resort to the wrench only for setting them up to full tension. This is essential for convenience of assembling, which is an important part in the production of the machine, and for the use of the product in service.

As an example we may take the bolts of the demountable tire rims of the automobile wheel. The nuts for these bolts should be a reasonably good fit. At the same time, in order to get quick interchangeability, they must not fit too close; that is, they must turn with a certain degree of freedom, yet the service they render is so important that they must be a little closer than a wringing fit, but must not be a tight wrench fit, at least at the outer end of the screw. While the limits of a screw fastening for this service are very small, the case illustrates the fact that a given degree of freedom of play is necessary, but must not exceed a certain boundary. In certain kinds of agricultural machinery, for instance, a much larger freedom may be tolerated, and in fact is desirable.

The gaging not only determines this boundary line, but also establishes another boundary line which constitutes the maximum freedom of play of the two components.

For instance, a 3/4-in. 10-pitch screw, nut or bolt measures 3/4 in. at the largest diameter (called crest of the thread) of the bolt, but since the crest is not of great importance, we measure the screw at the flanks of the thread with V-point calipers. This we call the pitch diameter, expressed P. D. The P. D. of a full-sized 3/4-in. (0.750-in.) bolt is 0.6851 in. This we call the basic diameter for this thread. In general practice it constitutes the maximum size for a close-fitting screw, and in some instances the smallest size of the nut. In other instances, the smallest nut is made a few thousandths of an inch larger in order to give a certain degree of looseness.

If the smallest nut is made to this basic size, then this figure becomes the minimum boundary of the nut and the maximum boundary of the screw.

Since it is not practicable to produce screws of exact uniformity, it is customary to allow a certain range of variation. The range of variation is expressed in thousandths of an inch of tolerance.

For instance, for fairly good work we allow a range of two and one-half thousandths of an inch, usually expressed as 0.0025 in., and sometimes given in exact size, such as in this case would be 0.6826 in., which is 0.0025 in. less than basic size, 0.6851 in.

The tolerance of variation in diameter of the nut in the same way is expressed as 0.6851 in. as minimum size plus 0.0025 in. for maximum of 0.6876 in.; or, if there is to be a neutral zone between the largest screw and the smallest nut, then the smallest screw may be any size that meets the requirements, 0.006 in. being a certain ordnance practice for neutral ground. Then the P. D.

[1] President, Jones & Lamson Machine Co.; Vice-Chairman, National Screw-Thread Commission; Past-President Am.Soc.M.E.

of nut becomes 0.6911 in. for minimum to 0.6936 in. for maximum, the tolerance of variation of product remaining the same, 0.0025 in.

In the old practice of fitting one piece to another, or even in the selective fitting, it was a comparatively easy matter to keep within certain boundaries between two pieces, but in the new practice, if the total freedom of play between two parts is 0.004 in., and the minimum freedom of play between two parts is 0.001 in., we will see that it is necessary to have 0.001 in. for the neutral space and divide up the other 0.003 in. in tolerance in variation in the sizes of the two component parts of the screw-thread fit. If the tolerance is equally divided between the two parts, this makes a total variation of 0.0015 in. that will be tolerated in the nut and 0.0015 in. tolerated in the screw.

The interchangeability system therefore imposes upon us greater precision in uniformity of production in order to get this interchangeability; but notwithstanding this important handicap, the advantages of the interchangeability system are so great as to offset the disadvantages. In fact, a high degree of interchangeability brings a reduction in cost of product and a greater reliability.

The purpose of our gaging is to guide us in manufacturing these parts and to serve as a means for finally inspecting the work before it is put into service; for if a screw, for instance, is made by one manufacturer or department and sold to or delivered to another manufacturer or department, the screw must be passed upon by suitable gages to determine whether or not it comes within specified boundaries.

Fit of Screws in Relation to the Helix and Form of Thread

The form of the United States Standard thread, originally known as the Sellers Standard, is made by a cutting tool having an included angle of 60 deg. This tool is truncated or flattened off at the end to an extent that amounts to one-eighth of its travel per revolution. The top of the thread has a similar flat, and although this describes a perfect thread, it is well known that a perfect thread is seldom found in practice. Therefore, it is our object in gaging and inspection to measure not only the diameter and the various parts of the screw, but also the truth of the helix for a given advancement per revolution, the degree of departure of the screw thread from the specified 60 deg. of angle, and, in fact, each characteristic on which its form and reliability depends.

Threads are specified as having a lead of helix expressed by the number of threads per inch. For instance, a ¾-in. United States Standard screw has 10 threads per inch. It is essential that there should be as nearly as may be exactly that number of threads per inch. If we count off 10 threads on a screw and find that we have advanced more or less than 1 in., we say the lead is not true; that it is off so many thousandths of an inch.

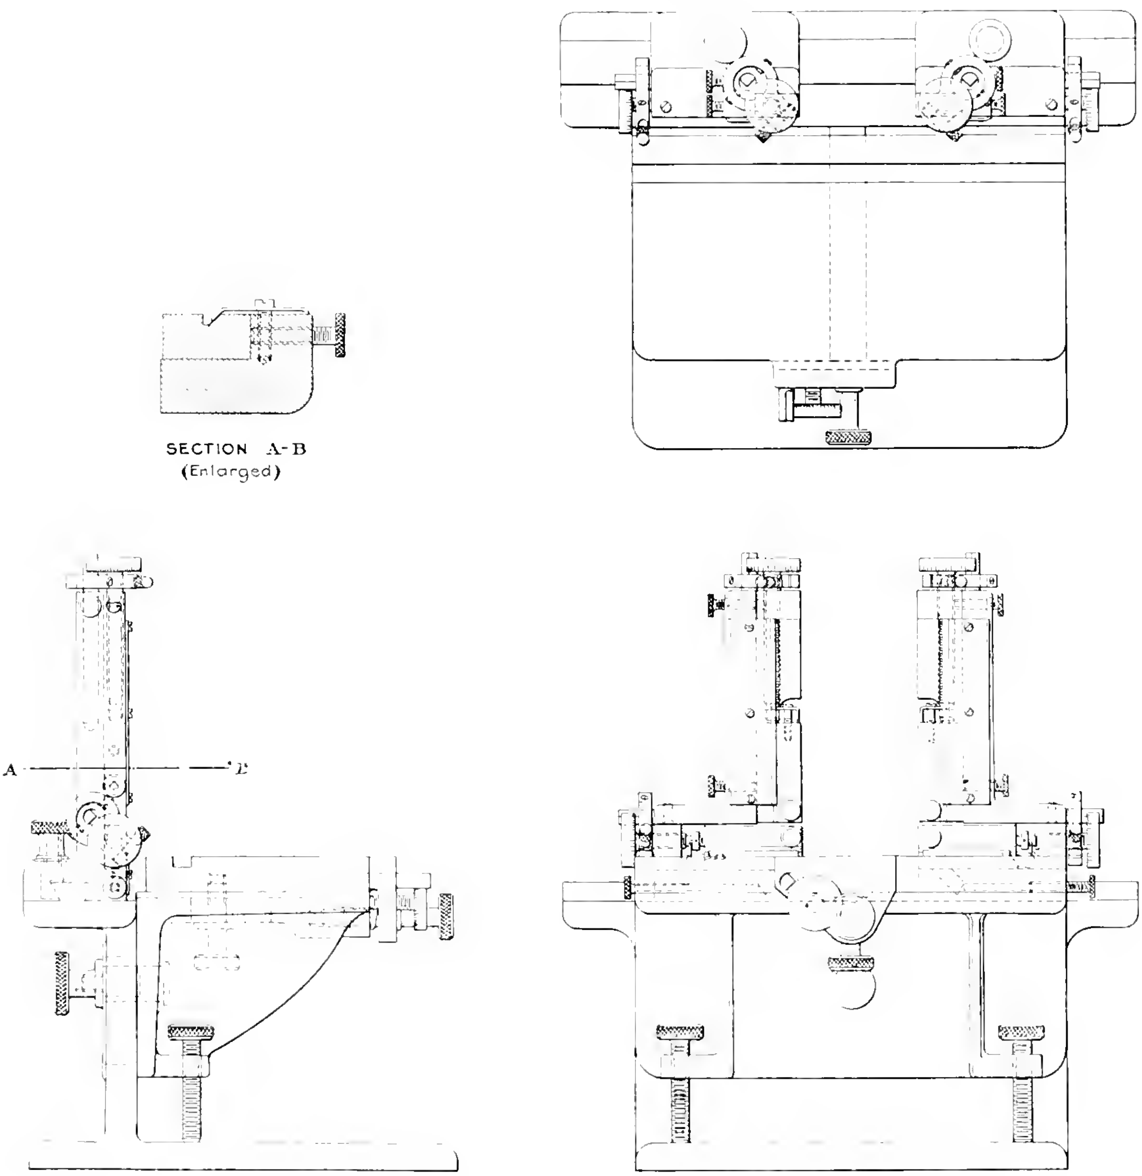


Fig. 1 Projection Machine for Inspecting Screw Threads

If the lead of a ¾-in. screw is "off" more than 0.003 in. or 0.004 in. per inch of length of engagement, it is unsuited for the best work, for when screwed into its threaded hole, which we will assume is accurate, the threads will not match; consequently, if they are of approximately the same size, the two may not screw together. But let us assume that the diameter of the inner member is enough smaller than standard to offset the difference in lead; then, although the two may screw together, they become less dependable when subjected to stress than if the threads of the two component parts matched each other; for it is obvious that there would not be an equal distribution of the stress of the work on the various threads that should be engaged.

Thus it will be seen that we not only have to consider the diameter but the lead, and in addition to this the form of the thread; that is, the form as shown by taking a profile that shows the flats of the angles of the sides. Then, since the helix may not proceed uniformly, may stagger forward, producing a thread which is known as a "drunken" thread, we must know about the degree of uniformity of this advance.

Besides this, we have to determine the roundness, for die-cut threads are frequently "out of round," due to excessive clearance of the cutting tools and inequality of distance between the two pairs of cutting edges in a die having four cutting edges.

We have also to inspect the screw for character of its surface. A die-cut thread, especially threads of 10-pitch and coarser, may be very rough and a microscope may show its surface as mountainous.

Furthermore, in addition to the measurements and character of its surface, the entire surface, including the tops and sides of the "mountains," may be, as expressed by one authority, "like a plowed field," as a result of the action of the cutting tools which, instead of cleanly removing the metal, have pushed or torn out the metal as if pulled out by the roots. This analogy, of course, is not perfect, but it gives a fairly true conception of the character of the surface, especially of a screw that has been produced by a single passing of the die.

Although some screw-cutting dies are designed to supplement the cutting process by a burnishing process which levels the "mountains" and compresses the "plowed-field" surface, the fact remains that nearly all screws of pitches coarser than 10 or 12 per inch have rough surfaces.

It is customary for the inspector to pass upon surface characteristics by close scrutiny. If it appears smooth, the screw is accepted, and if it is unduly rough for the service for which the screw is to be used, it is rejected.

Deficiencies of the Usual Gaging Methods

The process of gaging screws by the use of ring gages for the screw and the plug gage for the threaded hole is far from satisfactory for many reasons. The best practice uses at least two gages for each part. In gaging a screw, for instance, two ring gages are required. One is the upper boundary of size into which the screw must easily turn with a finger fit. The other gage is the lower one into which the screw must not enter more than one or two threads, according to the condition of the gage and the work.

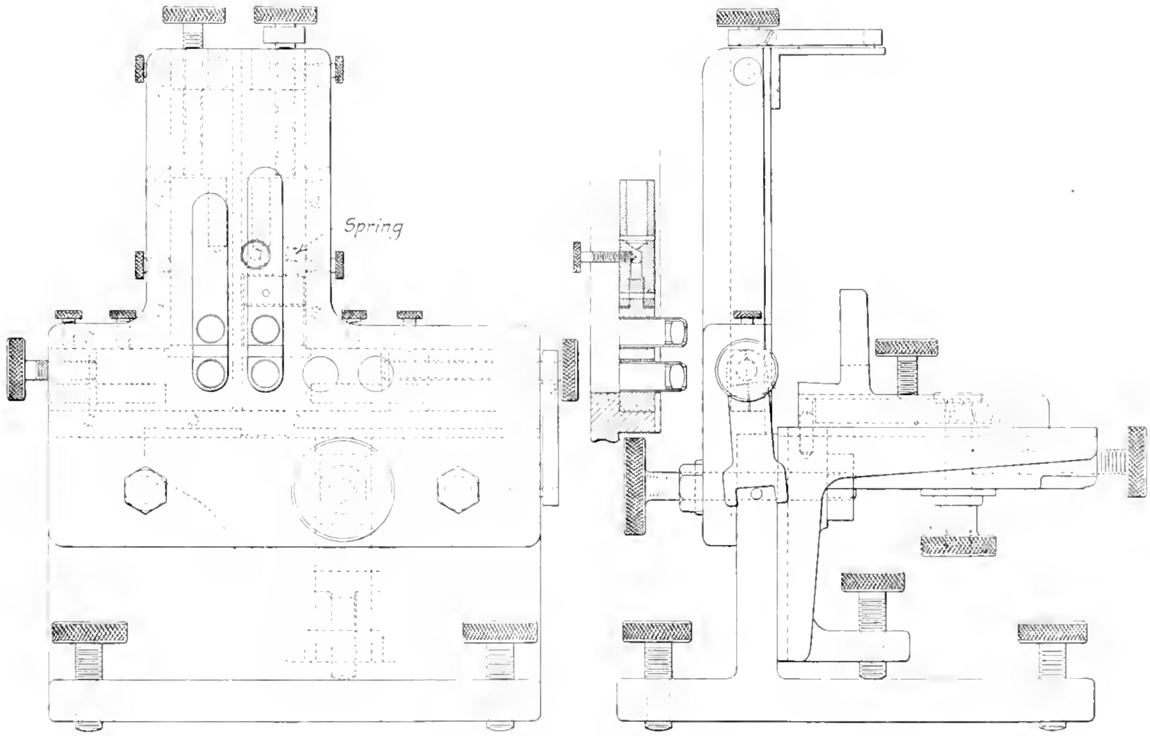

Fig. 2 Machine Designed for Smaller Range of Work

In still finer practice other gages are used to determine the lead, form and diameter of the crest and root, but in all such gaging processes the gage merely rides over the tops of the mountains, so far as the surface is concerned, and the extremes of the irregular helix, so far as the wabbling of the lead is concerned. Thus it will be seen that even with the best practice in use of the ring and plug gages, the process of gaging does not give a true indication of the dependability of a screw as a means of fastening.

A ring gage which is used for testing screws may become deceptive by the possibility of a fine, thin chip becoming lodged at some invisible point in the valley of the thread. For instance, if this is in a "no go" gage, and if the practice of the plant is to allow a screw to enter one or two turns into the "no go" gage on account of the wearing of the gage, a screw may enter until it encounters a chip of this kind; and then, since it can go no farther, it is passed as acceptable because it will not enter the "no go" gage beyond a specified distance for that particular gage.

The other elements of uncertainty readily come to the mind of one accustomed to precision measurement, and it is not necessary to go into all of these details.

In addition to the ring gages, we have the adjustable caliper in the form of the regular micrometer and the thread micrometer, and the fixed calipers, in which the points, although adjustable, remain fixed so far as the workman is concerned. These calipers, whether fixed or adjustable, give the diameter of the thread, usually measuring it on the flank, but this diameter does not give

a true indication of the roundness of the screw. For instance, if the screw is die-cut, the advance of the cutting of the die may be irregular, so that although any two opposite points in the diameter of the screw may be uniform to a certain measurement, as a matter of fact the screw has wabbled in passing through the die so that it has a series of longitudinal flutes or waves of more or less amplitude.

The caliper points for such work will find substantially a uniform diameter, although on one side one point of the caliper may be resting on a crest, while on the other side of the work the other point may be in a valley.

In the usual methods of inspecting there is also to be considered the personal equation of the inspector.

We speak of loose fits as "very loose," or with "very little shake," or still closer with "no shake."

Close fits are designated as "finger fits" when they can be turned on with the finger, as "wringing fits" when they require a little greater force, and as "wrench fits" when they require more force than can be exerted by the hands without the aid of wrench.

These are some of the shop terms that are in common use between men who are skilled in the work of making screw-thread fits of a dependable kind. They were fairly satisfactory between men skilled in this work, but they become misleading when put in general use.

To the skilled worker they meant that the fit for two component parts of a screw-thread fastening that were of known lead, shape of thread and fineness of finish, should be made to satisfy this tactile test, but the tactile test leaves the science of screw-thread gaging in a most difficult situation, especially with the modern advance in which specialization has so divided the work that the various parts of a piece of mechanism may be made in different cities. A screw, for instance, may be made in one city, and the threaded hole into which it fits be made in another city.

When we realize that for a close fit the total allowance is extremely small, and wholly disappears by the usual variation in machine product, we begin to see the difficult situation that has come with the higher development of machine construction, and we see that this tactile method, which depends so much on the personal equation of the individual inspector, leaves the producer always in doubt as to what will be acceptable, for he has no positive indication of the ruling of the purchaser.

Gages Do Not Definitely Determine Shape and Character of Thread

What has been said thus far applies merely to gaging screws that are known to be correct both in form and finish of surface. A simple plug or ring gage gives no indication of the exact form of a thread. In fact, when these gages are supplemented by others cleared at the root and crest, we are still in doubt as to the form of the effective surface. With this important element unmeasured, our gaging system is incomplete, even if it were satisfactory in other respects.

Thus far, also, we have considered the two component parts of a screw-thread fastening as if made of material that was neither elastic nor plastic. If this were true, our screw threads would be most undependable, but since it is not true, and since the threads of the two component parts may be forced together under wrench, or subjected to the stress of work, the engaging flanks of the threads of the two component parts are gradually squeezed into fitting surfaces. The stress levels the "mountains" and compresses the surface, and if the angles of the flanks of the two threads are not similar, this stress to a certain degree compresses the metal into a shape that gives perhaps a nearly perfect form of contact.

This squeezing changes the size and form of the thread surface and hence our gages cannot indicate what the shape and diameter of the screw will be when these "mountains" have been leveled and the "plowed-field" surface compressed by the action of the working stress.

Our gaging method is such that we must never exert pressure that will level down this surface, for by even the most careful use the gage wears out of shape, and it is considered very bad practice to force a gage.

Thus it will be seen that although we use our greatest care in the measurement of the screw thread as it comes from the machine in which it is produced, our gaging system makes little recognition of the shape, form and dimensions of that screw after it has been put under its working stress. It must be remembered that nearly all screws, excepting those used for precision adjustment, must be subjected to considerable stress in service, and that the end and aim of our gaging system should be to determine the fitness of a screw for its service.

Screw-Thread Requirements in Advanced Practice

The advancement of the art which has come about through the development of the bicycle, the automobile and the airplane has reached a point in which it is absolutely necessary to inspect screws in a way that will give a much better indication of their dependability. Before the art had advanced to this point where it was necessary to obtain the greatest strength for a given weight, a simpler system of gaging was satisfactory, but now, to make the most dependable airplane, a screw thread should be gaged for form, diameter, pitch, roundness and compactness of surface. The gaging should be done with full consideration of the changes that are produced in the lead, form and diameter when subjected to the working stress.

It seems probable that with the advance of requirements in machine construction we must go a step further in our gaging methods and make use of the projection lantern to help us solve our screw-thread gaging problems. The optical method of inspection and measurement of screw threads by the use of microscopic apparatus and projection lantern has been found invaluable in inspecting gages, but it has not been generally used for the inspection of the work itself.[1]

The tactile or touch method of inspection does not give us a true indication of the form of a screw, and even with a variety of instruments it gives only an approximate conception of the lead.

Notwithstanding the shortcomings of the ring and caliper types of gages, they still remain among the most practical gages in the workman's hands; and although the projection lantern brings the gaging to a definite science, and should be the basis of specifications for screw threads and the final arbiter in accepting or rejecting the product, its function is more to keep a check on the simpler forms of gages than to supplant them.

For instance, the first and last pieces of a lot of die-cut screws should be tested by the lantern. A change of dies, either through wear or important adjustment, should be checked by sending a sample screw to the lantern. This supplemented by the percentage test of the final product would be sufficient check, for it would give a definite knowledge of the character of the form, lead, roundness, etc.

The projection lantern has been developed to a point where it now gives at a glance the diameter, lead, form, and a fair indication of the roundness and smoothness of the surfaces. In order to get all of these results it is necessary to use in connection with the projection apparatus a stage and tolerance chart laid out on a large scale to conform to the desired characteristics of the screw to be inspected.

The chart is so located that the profile of one or more threads of the screw may be projected on to the chart and a comparison made between the enlarged shadow thus cast by the thread and the form of thread and tolerances outlined on the chart. (A more detailed description of the projection apparatus and chart is given later.)

[1] The work that has been done in the development of this method for testing gages is set forth in the paper of Mr. H. L. Van Keuren, presented at the 1918 Annual Meeting of the Society (see The Journal, November 1918, p. 913). Mr. Van Keuren as Chief of Gage Testing at the U. S. Bureau of Standards describes the excellent work under Dr. S. W. Stratton, Director, and also mentions the pioneer work of the National Physical Laboratory, Sir Richard Glazebrook, Director, and the progressive work of Mr. H. J. Bingham Powell at the British War Mission, New York City. For information regarding such use, see publications of these institutions.

Advantages of the Projection Method of Inspection

The advantage of the projection method is that it is possible to see at a glance how a screw will fit in its threaded hole as represented by the tolerance chart on the screen. If only one thread is projected on the screen, this is raised or lowered by variation in diameter and displaced laterally by variation in lead. The combination of these two things must be known in order to know how the screw will fit into the threaded hole. If two threads are projected we have a knowledge of the parallelism or taper of a screw.

In the Progress Report of the Committee on Limits and Tolerances in Screw Thread Fits, presented at the Spring Meeting of The American Society of Mechanical Engineers in 1918, tables will be found showing what reduction in pitch diameter must be made to offset certain errors in lead. For instance, the basic pitch diameter of the ¾-in. 10-pitch screw is 0.6851 in., and if the lead of the screw is true, the pitch diameter may be made up to this full diameter; but if the error in lead is plus or minus 0.002 in. in the length of engagement, then the pitch diameter must be reduced 0.0026 in.

Even in the best work, however, such allowances for difference in lead are seldom calculated. We merely know that if the lead is "off" we must reduce the effective diameter.

By the use of the projection apparatus and the tolerance chart all elements excepting the density of surface may be seen at a glance. The resultant effect of the displacement in lead, diameter and angle from the boundaries established on the tolerance chart indicates the fit with a definiteness that will be beneficial alike to the producer and the purchaser, for it will make it possible for the purchaser to express in words and by diagram the exact boundaries within which the product must come.

In addition to providing a measure for the lead and diameter, the tolerance chart and projection apparatus provide a way by which it is possible to indicate the extent of variation in the form of the thread that will be tolerated.

As the art of machine building advances and our methods for producing and gaging screw threads advance, we shall doubtless soon arrive at a point at which we will find it desirable to indicate the difference in lead between the two component parts of a screw-thread fit. For instance, stress of work on a bolt or nut tends to lengthen the screw and compress the nut, so that if the leads of the thread in the screw and the nut were equal when free from stress, there would be an unequal distribution of the load on the various threads engaged when the two members were under a heavy stress.

The stress on a set screw compresses the screw, and to get equal distribution of load on each thread the set screw should be long in lead when free from stress, and the lead of the bolt and nut should be longer in the nut than in the bolt.

To meet such demands the projection-lantern scheme furnishes a solution of one half of the problem, for gaging is half of producing the work. If we have a practical and ready method of gaging, it is much easier to produce the work. By the use of the projection apparatus the specifications may call for cap screws showing the displacement due to lead in one direction, and set screws in the opposite direction.

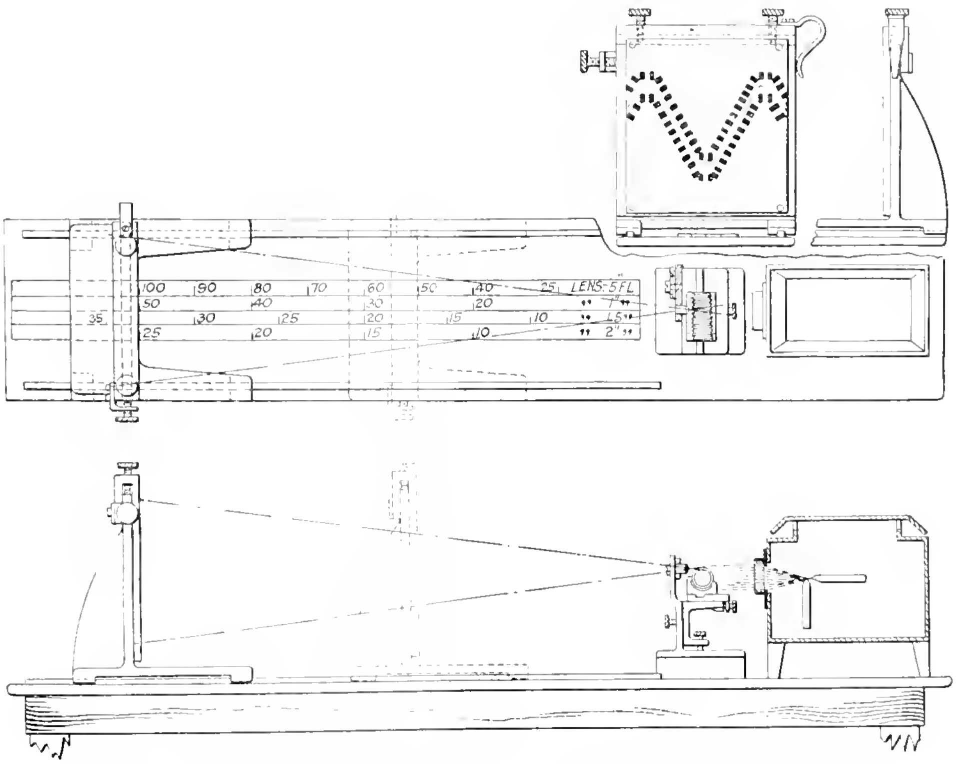

Fig. 3 Diagram Showing Essential Parts of Projection Apparatus

Measurement of Internal Threads

While the projection apparatus does not provide a solution for the measurement of the internal thread, it does provide means for measuring the tap which is used for producing the internal thread, and although it is well known that the usual way of measuring a tap does not indicate the exact nature of the threaded hole that will be produced by that tap, it is probable that a complete inspection of the tap by the projection methods will bring a closer harmony between the meaurements of the tap and the threaded hole produced by it.

Furthermore, the advance of machine construction has demanded for a number of years a greater refinement in tap making, and although the most progressive companies in this work have shown a remarkable advance in this respect, we are undoubtedly coming to a time when taps will be lapped or ground after hardening to bring them into greater uniformity.

Thus it seems that the advent of the projection lantern into the workshop for testing a certain percentage of the work produced will result in making our airplanes and other machines which operate under great tension for given dimensions more dependable and more efficient, and at the same time get a greater return for the energy that is put forth in the workshop in producing these things, for no one thing has been a greater barrier to our progress, especially in our recent war activities, than the uncertainty in our methods of specifying, producing and testing screw threads.

Description of Projection Apparatus and Chart

Fig. 1 represents a machine in use at present, excepting as it has been modified from time to time with various forms of work supports. Fig. 2 indicates a machine designed to take a smaller range of work.

Fig. 3 gives a side elevation and plan of the general scheme, although not true to proportions. The lamp house, for example, is shown too close to the object. The apparatus consists of three principal elements: the machine, which holds the work and lens; the lamp house; and the chart holder, which serves as a screen on which the profile of the thread is projected. The chart holder slides on rails to and from the work in order to get the desired number of magnifications.

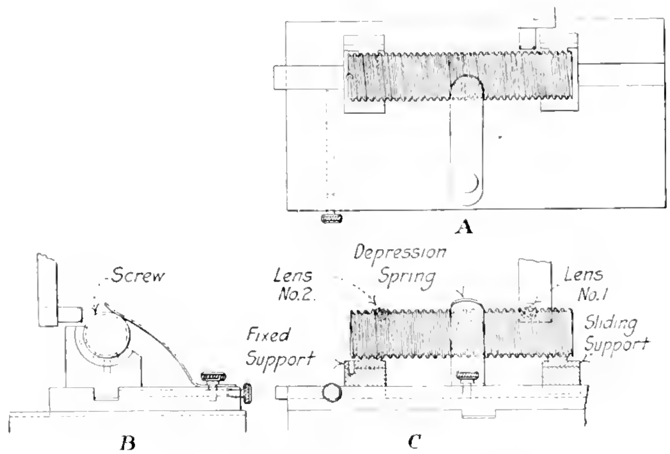

Fig. 4 Work Holder or Cradle

The general plan of operation starts with positioning the work and adjusting the light, work, lens and chart so that the image of a perfect screw thread will fall on the chart along certain lines. When we have no sample of work on which the thread is known to be satisfactory, a standard screw-thread plug may be put in the work holder and used for setting the chart. After that the work may be placed in the machine, one piece after another, and instantly its shadow will reveal its diameter, lead error and profile. If these fall within a certain range of tolerance on the chart the work is acceptable.

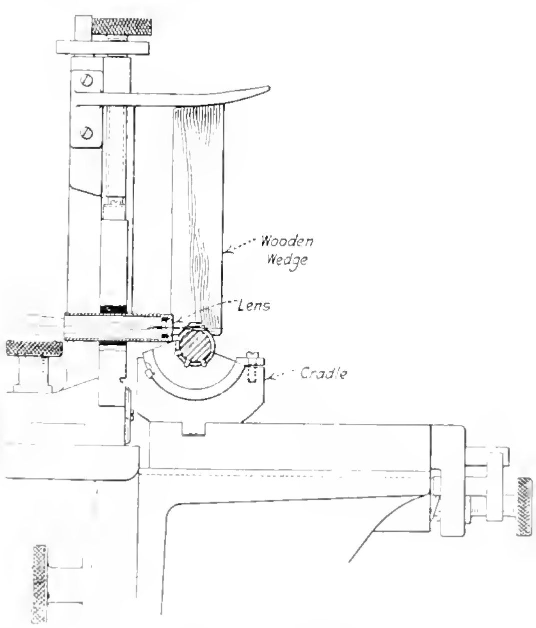

Fig. 4a Method of Holding Screw in Place for Testing

The simplest method of screw inspection projects the profile of one thread on a chart that has a maximum and minimum boundary. The maximum boundary represents the outline of the thread of the hole into which the screw must fit and the minimum represents the smallest acceptable diameter.

Work Supports. It has been found necessary, in order to meet the usual run of work, to mount the screw in one or two cradles consisting of nearly a half-circle of a nut and embracing from one to three threads of the screw, according to the character of the work. With this form of mounting, it is possible, when projecting one of the threads to a tolerance chart, to get some indication of the roundness and roughness by merely turning the screw in its cradle.

Three views of supports of this type are shown in Fig. 4 at *A*, *B* and *C*. The threads of the supports are interrupted with notches so that turning the screw in the thread will tend to carry out chips or other foreign particles that otherwise might be lodged in the thread. A spring is indicated for the purpose of giving the screw a downward pressure to hold the work firmly into its seat when it is being rotated by hand, the extent of this contact and pressure being different for different grades of work. On a $^3/_4$-in. rough screw I have used a wooden wedge which slipped readily into place and enabled me to get uniform results, as shown in Fig. 4*a*.

If the thread to be tested is very short and on a shaft or bolt of considerable length, one of the cradles may be threaded to fit the screw, and the other may fit the cylindrical body of the bolt or shaft.

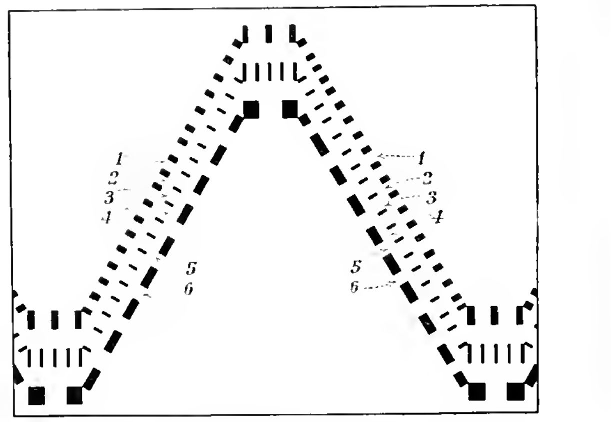

Fig. 5 Tolerance Chart (Greatly Reduced)

Although this method is subject to the uncertainties due to fine chips or other particles becoming lodged in the cradles, these things are more easily detected because the cradle is open and can be frequently inspected. Since a standard plug thread gage is the check on the adjustment of the projection apparatus, it may be dropped into the cradle at frequent intervals.

The object of using a cradle instead of single points, such as center points or single point contacts on the flanks or other parts of the screw, is to get a truer knowledge of the fit of the screw in the nut. The extent of area of contact of the cradle should be proportioned to the roughness of the work. Threads produced by the best methods of chasing on centers could use cradles with simple contact points.

Cradles are better than center points because 0.001 in. variation in diameter is fully shown on the chart, whereas by the use of center points with the projection of a single thread, 0.001 in. would show a variation on the chart of only half that amount, and although by confining the projection to one thread with parts of two valleys, a high magnification of 200 will give a displacement of 0.2 in. for each 0.001 in. of variation, the fact remains that it is desirable to get the best result with the minimum handicap. For instance, a small chip on a center point, when one is looking for an error of 0.0005 in., is more serious than if the chip were imbedded in a cradle.

The Condenser Lens may be a simple plano-convex, or it may be a combination of lenses to gather rays at a wide angle and condense them into a very small bundle of parallel rays. The essential thing, of course, is to have the rays travel in a parallel

direction when they reach the screw thread, striking the screw thread at the angle of the helix in order to present the sharpest profile for the lens.

In order to bring the screen as close as possible to the operator, I prefer to use a lens of very short focal length. For instance, for ½-in. size I am using 0.43 in. focal length, and this could be conveniently used for $\frac{5}{16}$-in., but for ¾-in. screws and larger the outside diameter of this lens would conflict with the sides of the screw, making it necessary to cut away part of each thread.

Tolerance Chart. The exact form of the chart will vary with different requirements, but I prefer a chart on which the boundaries indicated have stated gradations. For instance, for a screw thread of 10 pitch at 200 magnifications the outline of the thread form measures 20 in. between centers of crests of thread, and I produce a chart by drawing these forms in light pencil marks, in steps spaced at 0.8 in., which amounts to 0.004 in. variation of screw thread, for at 200 magnifications we have 0.2 in. per thousandth of an inch. Such a chart is shown in miniature in Fig. 5.

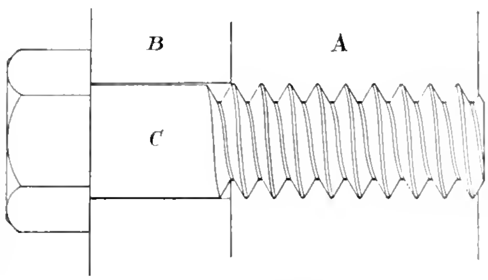

Fig. 6 Ideal Screw-Thread Fit

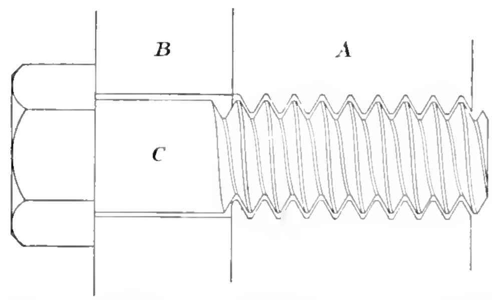

Fig. 7a Screw of Fig. 7 Placed in Central Position

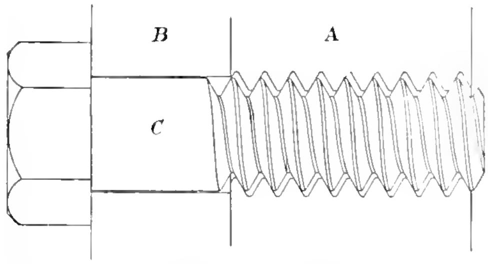

Fig. 7 Screw Smaller Than Threaded Hole

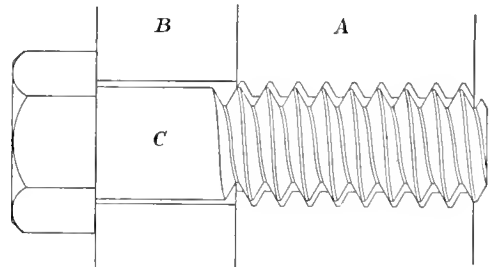

Fig. 8 Screw Standard but Threaded Hole Too Large

Inasmuch as it is not easy to locate the shadow in relation to straight lines, I use black dots having a vertical width of 0.8 in., which amounts to approximately a width of ⅜ in. on the flanks of the thread. These dots are made of different lengths so they may be readily recognized in the partial light of the projection room. The light of the projection room should be adjusted to see the black dots, even in the shadow, and yet not too light to dim the shadow.

By numbering the lines of the charts from 1 to 6, beginning at the upper and running to the lower side, we have means for recording, if necessary, the measurements of a screw. For this purpose we would set up the instrument with a standard plug gage or other perfect thread so that the shadow of this perfect thread would fall on line 5, and this would constitute the largest size that would be tolerated for free fits, the plug being the basic diameter.

Let us assume that the allowable tolerance at the pitch diameter of a 10-pitch screw is 0.008 in.; that is, that the screw may be up to the full basic standard line No. 5 or it may be 0.008 in. smaller, in which case the shadow should not proceed farther than line No. 3. Then by placing one piece of work after another in the holder, if the shadow falls within these boundaries of 3 to 5, we know its size is acceptable. If its shadow falls below line No. 5 toward No. 6, we know it is too large for that grade of fit.

Magnification of the Profile. The distance of the chart holder from the focal center of the lens must be as many times the distance from the focal center of the lens to the profile of the thread as the number of magnifications required. If the focal length of the lens were 1 in., the screen would have to stand away 200 in. to get a magnification of 200 diameters. With a 0.43-in. focal length we get 100 magnifications at 43 in. and 200 magnifications at 86 in. At a distance of 86 in. the shadow can be easily seen by the operator.

I am aware that in astronomy and other sciences using lenses, it is the novice that goes to the higher magnifications, and that the magnifications should not be greater than required, as the best result is obtained by the lowest magnification that will give the proper definition. And while I am aware that those who have been in this art for some time in testing gaging devices advise the low magnifications, it would seem to me that there may be a special reason for using large magnifications in this scheme for testing the work itself.

In this plan we have little or no occasion for projecting more than a single profile, or if we project more than one of the threads, we superimpose the shadows so that the dimensions of the chart may be kept down to about 25 in. square for the run of work of standard threads up to 8 pitch with magnification up to 200.

Characteristics of Screw-Thread Fits

Figs. 6, 7, 7*a*, 8, 9 and 10 illustrate three elements of an ordinary screw-thread fastening. *A* and *B* are pieces to be forcibly held together by a cap screw or bolt *C*. A hole is drilled in *B* large enough for the whole of the screw to pass through it, excepting the head, and *A* has a tapped hole into which the screw is turned.

Fig. 6 represents an ideal screw-thread fit in which the flanks of the thread of the screw and the threaded hole closely fit the entire length of the screw.

Fig. 7 illustrates an extreme example in which the screw is smaller than the threaded hole so that the threads engage only three-quarters of the entire depth of the full engagement.

Fig. 8 illustrates a fit in which the thread diameters are the same when measured on the pitch line, but shows an example of a threaded hole in which the crests of the thread are not up to the full size owing to the hole having been drilled larger than the root diameter of the tap which produced it.

Fig. 9 shows a screw-thread fit in which the diameter of the screw is a trifle smaller than the diameter of the threaded hole, but the threads are not equally spaced so that it is just barely possible to turn the screw into the threaded hole, for it will be

seen that the flank of the thread at x and y bears in opposite directions, while the flanks of the thread at z stand clear.

Figs. 7 and 8 show the flanks of the thread properly engaged; that is, each thread bears its proportionate part of the load; whereas, in Fig. 9, the whole load comes first on a single thread at x. In practice, of course, ordinary differences that appear in lead result in the stress crushing down the first thread at x and gradually working back until they may be distributed the entire length, but not equally.

A reversal of the difference in lead, that is, making the thread of the bolt shorter than the thread in the threaded hole, puts the burden of the work first on the thread at y, and then gradually, either through crushing down of the first threads engaged or by stretching out of the length of the bolt, brings a distribution over the other threads.

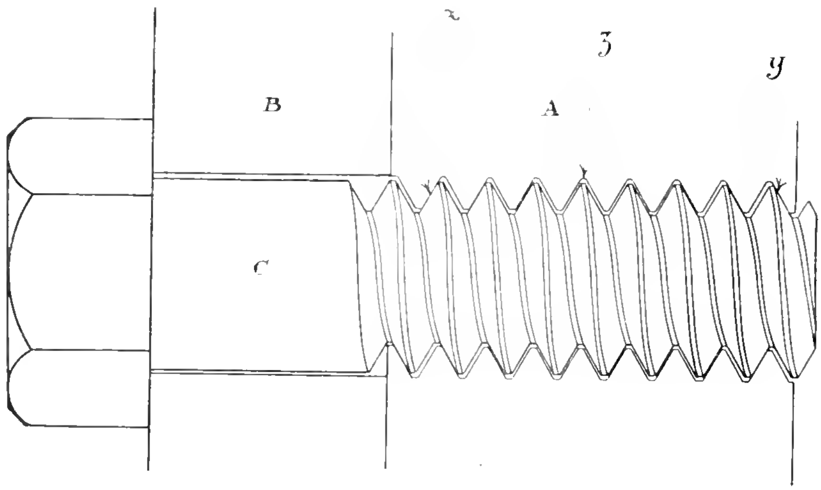

FIG. 9 LEAD OF SCREW GREATER THAN THAT OF THREADED HOLE

In making screw-thread fits we have not only the element of difference in diameter with true leads, but we have combinations of lead errors and diameter variations. It is obvious that with perfect lead the diameters must correspond to insure a depth of engagement that will prevent stripping under the working stress, and in addition to this, if the screw is one that is frequently adjusted and must have good wearing qualities, the depth of engagement must be great enough to provide ample wearing surface.

In addition to the foregoing elements, we have to consider the form of the thread. In Fig. 10 is shown a threaded hole in which the thread is of a blunter angle than the thread of the screw, and while this is not as serious a matter as may seem at first glance, for it has been found perfectly practicable for ordinary fastenings to use a 55-deg. Whitworth thread in a 60-deg. U. S. Standard, the fact remains that it is one of the elements that we must consider in determining the dependability of a screw-thread fastening, for the thread under stress must be squeezed into a shape that will produce a uniformity of contact over a fair amount of the flank surface. Our system of screw-thread gaging should take into consideration form as well as diameter and lead.

The foregoing figures illustrate the three elements, A, B and C, as they would appear when screwed together under a light stress. No attempt has been made to show the various degrees of change that take place under the enormous stresses of the work, although we are coming to a state of machine construction which demands a consideration of the form of thread when under stress. For the purpose of illustration and comparison of the optical gaging system with the tactile gaging system, that is, the system in which we see the condition of a screw as against the system in which we try to determine it by the sense of feeling, we will for the present ignore such stresses.

If we substitute Fig. 7a for Fig. 7, in which a small screw is shown in the threaded hole, but instead of being pulled to one side it stands clear, showing the amount of clearance there would be around each side of each thread—if we will take this for Fig. 7, we will find that the various fit conditions can be found by glancing at the thread at the end of the engagement; for instance, at point y or point x, as in Fig. 9.

Since the error in lead is equally divided between the opposite ends of the length of engagement, it is the end threads that tell us the story.

In the optical-projection method we so locate the screw before the lens that the shadow is thrown on the screen. A lateral displacement of the shadow will clearly indicate the lead error, and a vertical displacement a variation in diameter. The combination of the two will locate the shadow of a single profile on the chart in a way to indicate the condition at the end of a thread engagement of a given length. This tells the whole story of the resultant effect of diameter, lead and form of thread, for one of the boundaries of the chart may be considered as the interior profile of the threaded hole.

FEATURES DEVELOPED BY INSPECTION

The average run of work with the projection lantern will present some new thoughts to the inspector's mind. He will see that the lead is not uniform. In the length of a 3-in. screw the lead at one end of the screw may be shorter than at the other end. He will find that many screws are not round and some are very irregular and mountainous on the surface; not that these elements have been created by the projection apparatus, but merely that they have been brought clearly to view and should be recognized by any system of gaging that has for its ultimate purpose determining the dependability of the screw.

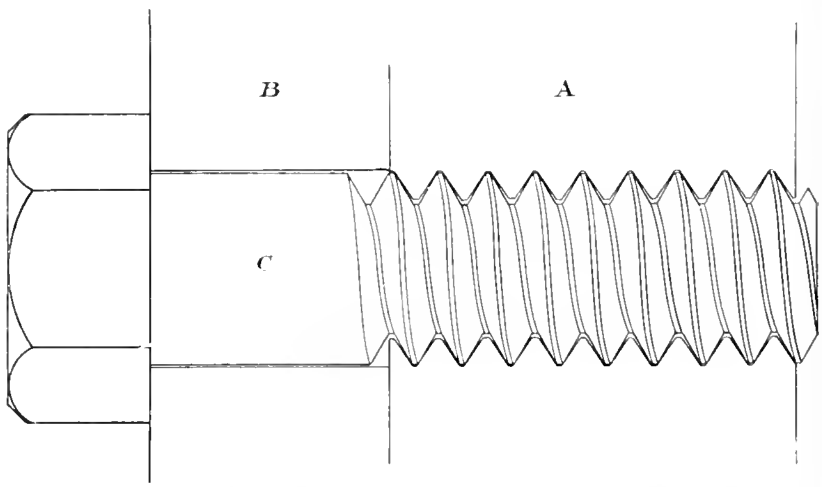

FIG. 10 THREADS OF SCREW OF DIFFERENT ANGLE FROM THREADS OF HOLE

Rotating the work in its holder brings out irregularities. If the screw is of good form, its shadow will remain stationary on the chart. If the thread is drunken, out of round or very irregular, the shadow will move. A ragged surface also appears in the unevenness of the line, and frequently the inspector is confronted with the necessity of determining what part of the line he is to designate as indicating the real working diameter of the screw.

It is not unusual to find one of the flanks of the thread, instead of presenting a straight profile, shows for instance a ridge near where the crest of the thread is rotated.

This condition has always existed in screw threads, and it is for us to recognize that the projection method merely shows how deceptive has been the gaging system which depended on the tactile sense or sense of "feel" of the gage.

In gaging this ridge would play an important part in elim-

inating shake, and yet the screw might be under size so far as its holding capacity is concerned.

When we see the displacement of the thread laterally, that is, if we assume that the profile of the thread on one side is on No. 4 boundary and the opposite side on No. 5, we will know that its lead is off to that extent, and that when turned into a nut the full length of the nut it will feel the same as a perfect thread. But as a matter of fact the slack will be taken up by opposite sides of the flank at opposite ends of the nut, while the middle may not be in contact.

Let us understand that line 5 represents the inside of the nut or at least the upper boundary for the screw. Now, in order to get a perfect indication of the fit of an inaccurate lead in a perfect nut, it is necessary for us to see that our holder which positions the work is adjusted in relation to the length of the engagement of the thread in the nut or in the threaded hole. For instance, if the lead is long or short we know that as it screws into the nut or threaded hole the difference in lead will cause the screw to fit in the nut as shown in Fig. 8, if the screw is longer than that of the nut, and on the opposite sides of the threads if the screw is shorter.

Now we must adjust our holding means so as to get a view of the thread at the end of the nut, which, of course, determines the closeness of its fit.

In Fig. 4, previously referred to, are three views, *A*, *B* and *C*, of a screw located in the cradle of a projection machine. In order to make the view projected on the chart duplicate the conditions in the nut, it is only necessary to see that the longitudinal distance between the distance of the fixed support and the lens (position No. 1) is equal to the length of engagement of the thread in the threaded hole. (If the screw were held on center points instead of on a cradle this fixed support would be one-half the length of engagement.)

It will be understood that the fixed support locates the screw in its longitudinal position as well as laterally; that the sliding support, although holding the screw in the right focal distance from the lens, adapts itself to the position of the thread which, if the lead is true, will be the same as a standard thread, and if the thread is short or long will move endwise without changing the vertical gage of the screw. The projection through the lens will then be displaced vertically if there is a difference in diameter, and displaced laterally if there is a change in the length of the lead.

The combination of these two when the distance to the fixed support is equal to the length of engagement gives a definite knowledge of the fit, and while it may be disturbing to know that the fit is not a fit in the true sense of the word, that it is a misfit is 99½ per cent. of our work, it is best to know the truth if we are to make our machines dependable.

A lens located in position No. 2 can be adjusted to throw its shadow simultaneously with lens No. 1; or a shutter may be used to alternate these two. The object of lens No. 2 would be to check the parallelism of the screw. If the vertical position of the thread projected by lens No. 2 corresponded to the vertical position of the thread projected by lens No. 1, we would know that the thread was parallel.

If it were desirable to have this test for each screw that went through the instrument, its shadow could be so located as to fall two numbers lower than the shadow from lens No. 1, so that the range of its position would be from line 1 to line 3 on the chart, Fig. 5, while the range of the other position would be from 3 to 5, and the uniformity of the average distance between these would constitute an indication of parallelism.

The essential thing in gaging the rougher screws is to see that the screw is held down in its supports with sufficient pressure to insure good contact.

MARINE PRACTICE IN VALVES AND FITTINGS

A Paper in Which the Author Suggests That Certain Features of Central-Station Practice Be Extended to Marine Practice

By A. G. CHRISTIE,[1] BALTIMORE, MD.

THIS paper consists of a series of comments on certain marine practices in regard to valves and piping, from the viewpoint of a central-station man. In recent years there has been a wide use on shipboard of such types of central-station equipment as water-tube boilers and superheaters, geared turbine units, high-vacuum condensers with rotary and ejector air pumps, and centrifugal boiler-feed pumps. Marine practice, however, has lagged behind central-station practice because of the well-known conservation of ship owners.

It has taken this world war to accelerate the adaptation to ships of much of the standard central-station apparatus. Certain factors are now at work which have considerable influence on present marine practice in valves and piping. Of these the greatest is the fabricated-ship yard. In the old-style yard the shops would make up any or or all of their fittings or valves to their special designs, each yard having its own designs which differed from those of other yards. The result of this was a constantly increasing number of special valves and types in each shipyard, with the consequent increase in cost of ship construction. The fabricated-ship yard, however, was forced to buy in the open market and in order to get deliveries had to purchase standard types and sizes. This made engineers study their valves and endeavor to standardize them. In one yard it was thus found possible to reduce the number of types by 20 per cent. It is entirely practicable to use manufacturers' standard stock patterns for nearly all valves, fittings and auxiliary equipment. This standardization, with consequent reduced costs, will be one of the deciding factors in maintaining our shipbuilding supremacy after the war. Standard valves require fewer repair parts and these are more easily procurable for renewal. Decided advantages may be gained by still further extending present standardization.

Piping

A factor which has influenced piping practice is the availability of materials. For instance, copper piping in sizes suitable for steam mains has become so scarce that open-hearth lap-welded steel pipe is often adopted in its place. The use of copper piping has long been standard practice on shipboard. This piping has considerable flexibility and generally stands up well in marine service, but it is not well adapted to superheat conditions. Steel pipe is much cheaper than copper pipe, is more readily available, and is well adapted to any pressures and temperatures that may be encountered. Some engineers fear that it may lack the flexibility of copper pipe, although steel piping in central stations is frequently subjected to strains from contraction and expansion as severe as one finds on board ship; and furthermore is frequently subjected to severe stresses due to unbalanced turbine rotors and other harmonic vibrations. The substitution of steel for copper piping is merely a matter of marine engineers becoming accustomed to designing and installing their steam systems in accordance with steel-pipe standards. In other words, it is dependent on their ability to break away from traditional practice.

[1] Associate Professor of Mechanical Engineering, Johns Hopkins University. Mem.Am.Soc.M.E.

Presented at a meeting of the Baltimore Section of The American Society of Mechanical Engineers, November 20, 1918.

Steel pipe, however, does not withstand corrosion as well as copper pipe. Galvanized steel pipe has been tried for this purpose. In time the galvanized material flakes off under the influence of heat and causes trouble. Repeated painting of such steel pipe seems to be the best protection.

Galvanized pipe should be used on sanitary systems and bilge and ballast piping. However, no advantage is gained by galvanizing the cast-iron fittings of these systems. It is also questionable whether fuel-oil piping in oil-burning ships needs to be galvanized at all.

The problem of caring for expansion has made many engineers prefer copper to steel in piping. In general, long-radius bends provide the best means for taking care of expansion difficulties. Space is limited in vessels, but much may be accomplished in the way of providing such bends if a little study is given to the subject. Some have questioned the flexibility of bends of extra heavy steel pipe. Crane Company's tables indicate that there is usually ample flexibility to care for any lengths that are generally used on shipboard.

Pipe Flanges

Expanded flanges of the Lovekin or similar types are almost universal with copper pipe. Lovekin flanges are used to some extent with steel pipe, but welded or screwed joints are more common.

Land practice in piping seems to have advanced far beyond marine practice in the use of the Van Stone joint. It is said that the first installation of this type of flange on shipboard many years ago was not a success. Apparently this has condemned this excellent joint ever since. Although giving excellent service under most exacting conditions on land, it is taboo at sea. The welded type of Van Stone joint now in use in central stations has apparently never been tried out at sea.

Fittings

With superheated steam, and in general with all steam of over 150 lb. pressure, it is advisable to use cast-steel fittings on the steam lines. For pressures of 100 to 160 lb., extra heavy cast-iron or, better still, semi-steel fittings may be used. For pressures below 100 lb. cast-iron or malleable fittings of standard pattern may be used. In screwed fittings the collar over the threaded portion should be sufficiently heavy to prevent distortion when screwing up with pipe wrenches. Malleable iron is preferred by many on account of its lesser liability to rupture under stress. However, such fittings are generally lighter than cast-iron and are sometimes deformed in screwing up.

In central stations it is very common practice to find branch outlets welded to the main pipe and in general these welded pipes have given very excellent service. This practice is apparently very little used in marine work, although it would make a weight-saving construction by doing away with many cast-iron special fittings now used.

Valves

Standard types of valves must be bought if one is to place orders in the open market under present conditions. Steel valves are used for superheat. Some shipbuilders even specify steel valves for all boiler pressures of 200 lb. or greater. If superheat is not used the valves may be extra heavy, of cast iron or semi-steel. These materials are also used for auxiliary steam lines. Bronze valves are sometimes employed in the smaller sizes, but these are very much more expensive than the extra heavy cast-iron valves and in sizes of $2\frac{1}{2}$ in. and over have no advantage over them except in lightness of weight.

Valves $2\frac{1}{2}$ in. and above must have bolted bonnets to comply with the U. S. Steamboat Inspection Rules. The marine or cross-head type of yoke is much superior to the standard cast yoke for ship purposes. It weighs less and is generally stronger and more readily repaired. It costs very little more than the cast yoke, but is not "standard" with many builders. The latter yoke can be safely used for all low-pressure services.

It is customary on board ship to use the screwed-union bonnet on 2-in. and smaller valves. This type of valve is generally more expensive than the ordinary bonnet type, but has many points of superiority such as its regrinding facilities, longer life and less liability to damage when dismantling. Valve manufacturers generally make the screwed-union bonnet valves in two weights, one to withstand 200 lb. pressure, the other for 350 lb. pressure. It is therefore necessary to use the 200-lb. valves for many low-pressure services. This has considerable advantages, for fewer types of valves need be bought and their interchangeability is increased.

Cast-iron or semi-steel valves for marine service are usually required to have a solid bronze disk with bronze seat. The stem may be of rolled phosphor bronze, rolled naval brass or manganese bronze. Gland studs and nuts should also be of bronze. Steel valves for superheat generally have monel-metal disks and seats with bronze or nickel-plated steel stems. The bronze generally used for valve bodies, disks, seats, glands, etc., is the navy composition "M" consisting of copper 87 per cent, zinc 7 per cent, tin 6 per cent, and may contain lead up to 2 per cent in place of part of the copper. The lead content must be kept as low as possible on account of the action of the salt water.

It is the practice of many marine designers to specify a flange corresponding to extra heavy standard on the sea side of all sea valves, sometimes even when these are connected to the sea chests. Usually the valve is in all other respects of standard weight. This extra heavy flange adds nothing to the strength of the valve, for its weakest point is in the neck behind this flange, which is sometimes but not always made extra heavy. Some maintain that the extra heavy flange is needed to stiffen the ship plate. This same result is secured elsewhere by adding a reinforcing ring to the ship's plates. This type of valve is a "special" to the manufacturers and hence is high-priced and often difficult to obtain on reasonable deliveries.

Shipbuilders generally have endeavored to use A.S.M.E. standards for flanges and drilling. However, some criticisms have been heard. For instance, many marine engineers do not favor the raised faces on extra heavy flanges. They prefer flat faces. The flat faces are also favored for bolting to bulkheads and to other ship plates.

The bolting specified for certain sizes in the A.S.M.E. standards has not been satisfactory to many marine designers. For instance, in the 3-in. and $3\frac{1}{2}$-in. standard-weight flanges the A.S.M.E. standard calls for four holes, while many marine designers use six holes. Also, in the 2-in. and $2\frac{1}{2}$-in. extra heavy flanges the marine engineers frequently use six holes where the A.S.M.E. standards specify four. The A.S.M.E. standards increase the holes at one jump from four to eight. There seems considerable justification for the use of the six-hole flange.

One cannot help commenting on the small use made of gate valves on ships. These are especially adapted to fuel-oil service and could be used to advantage on many water lines just as in land practice. A greater use of gate valves would relieve the existing valve shortage to an appreciable extent and also reduce friction. Reducing valves, relief valves, separators, traps, injectors, etc., can all be supplied equally well from the manufacturer's standard stock patterns made for central-station work as from special marine designs.

It is rather difficult to understand the basis for marine practice in heating systems. Live steam is usually passed through a reducing valve and supplied to the heating system at 20 to 30 lb. pressure. The advantages of exhaust steam for heating and of steam bled from the main turbine do not seem to be fully appreciated in marine practice. Such uses of steam would make operation less simple, but would result in a thermodynamic gain, especially in passenger ships and troop transports.

Inspectors are frequently required to apply tests to valves. In general, such tests are specified in Lloyds and U. S. Steamboat Inspection Rules. A satisfactory standard for inspectors is to test all high-pressure steam valves under hydraulic pressure to three times their working pressure and to test all other valves to twice the working pressure corresponding to their weight or classification.

THE CHEMICAL AND PHYSICAL CONTROL OF BOILER OPERATION

Including the Application of Simple Formulae for Estimating the Heat-Loss Items, etc.

By E. A. UEHLING,[1] PASSAIC, N. J.

THE best method for attaining the conservation of fuel has not been definitely outlined by engineers. There is, therefore, room for discussion, and it is intended to treat the subject in the present paper from the chemical and physical aspects of combustion.

Before intelligent steps can be taken to bring a given boiler plant to its maximum efficiency, it is necessary to know with what efficiency the plant is working. Scientific refinement is not necessary in every-day practice, but *scientific reasoning must be applied*, and the data upon which reasoning can be based must be observed and, wherever possible, autographically recorded.

Methods of Controlling Boiler-Plant Operation

The economical status of a boiler plant can be ascertained by either of the two distinct methods, viz.:

a The mechanical method, based on the heat utilized

b The chemical and physical method, based on the heat wasted.

The mechanical method relies on the readings of the coal weigher and the water meter or steam-flow meter. If the heat value of the fuel is known, the data obtained by these appurtenances enable one to calculate roughly what percentage of the heat in the coal fired is utilized in making steam. For obvious reason the results cannot be calculated oftener than once a day and generally once a week is considered sufficient for a control over the operation of the boiler plant. Aside from the lateness in obtaining the desired information, this method suffers in accuracy and reliability as a control from the following errors and shortcomings:

a The coal weigher cannot discriminate between coal and ash and moisture, and since these constituents are never constant and frequently vary five per cent or more in successive shipments, and since the heat value of the fuel depends on its purity, the calculated results will be that much in error

b The water passed through the meter is not all evaporated. An appreciable amount may be carried over with the steam, more may be lost through leaky blow-off cocks, and considerable is wasted by blowing off the boilers, which is not only not accounted for but actually appears on the credit side

c The steam may be superheated

d The feedwater temperature may vary appreciably.

Thus we see that a water meter and coal weigher can give only a rough, wholesale control, unless supplemented by scientific instruments and observations. The mechanical control has another and even more serious shortcoming in that it gives absolutely no clue as to why the plant as a whole is operating more or less wastefully.

The wholesale chemical and physical method of control is based on the readings of a CO_2 meter and pyrometer inserted in the main gas flue at or near the chimney. This method suffers from the following deficiencies and inaccuracies:

a The indicated and calculated results are qualitative

b The results do not represent all the heat wasted

c From the CO_2 determination in the chimney gas one is unable to discriminate between excess air through the fire and that leaking through boiler walls, as well as that leaking into the gas flue between the boilers and the point where the sampling tube must be inserted to get the gas from all the boilers. Air entering beyond the boilers does not militate against efficiency except as it may overburden the chimney and reduce the draft below that required for efficient combustion.

The wholesale chemical and physical method has the following advantages over the mechanical method:

a It can be more easily and cheaply installed

b The records show up the collective operation of the boilers continuously instead of only at the end of longer or shorter periods; one day at best

c It shows up the combustion and absorption efficiency factors separately so that the proper steps to improve the efficiency of the plant can be promptly and intelligently taken

d The value of its records is not affected by a variation in ash or moisture content of coal burned. Nor is the record affected by the waste of feedwater nor the variation in its temperature.

From the preceding consideration it becomes evident that both wholesale methods are equally handicapped as an aid to improve boiler efficiency, and that in order to obtain maximum collective boiler efficiency each boiler must be diagnosed individually. To be under proper economic control, both its combustion and absorption efficiencies must be under constant observation. Maximum boiler efficiency cannot be maintained without *knowing what every boiler is doing all the time.* To this every combustion and boiler expert will agree; but opinions will no doubt differ as to the best means for effecting this constant observation. It would appear obvious that the most direct way is the best way. Combustion is a chemical phenomenon, and should therefore be most effectively controlled by chemical means. Absorption is a physical phenomenon and is best controlled by physical means. The two principal instruments of observation are the CO_2 meter, a chemical instrument, and the pyrometer, which is a physical instrument. As a necessary auxiliary the double differential draft gage is required. Boiler draft and furnace draft are essential elements in the proper control of combustion and should be observed separately.

The slogan for the boiler room should be: *Watch your results and change your adjustments to keep the results right.* There is no such thing as a fixed adjustment in the operation of a boiler. The rate of combustion must be changed to keep the steam pressure right, the draft must be changed to keep the rate of combustion right, and the thickness of fire must be changed to keep the efficiency of combustion (per cent of CO_2) right. As the fuel and ash bed thickens, a stronger draft is necessary to keep the required rate of combustion, and there are numerous minor variables which require changes in the draft adjustments if combustion efficiency and the required boiler capacity are to be maintained, i.e., maximum CO_2 and a uniform steam pressure. To insure these results CO_2 as well as boiler and furnace draft indicators must be placed at or near the boiler front within easy view of the fireman and in close proximity to the draft-regulating wheel or lever.

Information Afforded by Recording-Instrument Charts

The three autographic records, namely, those of CO_2, temperature of the escaping gas and the boiler draft, preferably on one chart, give the engineer in charge the following information at a glance:

a Whether normal combustion efficiency has been maintained; and if not, the precise time when it became abnormal and how long it remained so. This enables him to inquire into the cause, with the confidence born of knowledge, and to apply the proper correction. The continuous record further reveals in hand-fired boilers how often the fires were replenished, how long the fire doors were left open, when the fires were cleaned and how long it took to clean them. In stoker-fired boilers changes in handling the fire are similarly revealed

b The temperature record shows whether the absorption efficiency has continued normal; if not, the variation may be due to necessary variations in the rate of driving, and if so this will be revealed by the record of the boiler draft, which is

[1] President, Uehling Instrument Company. Mem.Am.Soc.M.E.

Presented at the Annual Meeting, New York, December 3 to 6, 1918, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

an index to the rate of driving. Or it may be due to a breaking-down of the baffling, which is also instantly revealed by the boiler draft. The mucking-up of the heating surface is indicated by a gradual increase in the temperature of the escaping gases

e The record of the boiler draft, in addition to its contributing value to the pyrometer record, becomes in combination with the per cent of CO_2 a very good index to the rate of combustion, as the writer will endeavor to show later.

Examples of Application of Information Given by Charts to Control of Firing

Fig. 1 illustrates sections of recording-instrument charts showing various relations of these three records to each other. The CO_2 records shown in Secs. 1 and 2 are facsimile samples of records from a boiler of the Manning type burning No. 1 buckwheat coal. Sec. 1, made when the recorder was first installed, shows that the firing was irregular and that the coal bed was kept too thin, through which holes quickly developed. The average CO was scant 8 per cent. The reason for the low CO_2 being thus clearly revealed, the proper remedy at once suggested itself. The fireman was instructed to carry a little heavier fire and watch the CO_2 indicator, with the result shown in Sec. 2, which is a sample record for the same boiler after the fireman had been instructed and had learned to be guided by the CO_2 indicator in adjusting the thickness of the fire to the draft necessary to maintain the required steam pressure. So guided he had no difficulty in keeping the CO_2 at an average of about 12 per cent. Having the three principal records on the same chart their relation to one another is readily perceived, and it will be seen at a glance that the boiler draft is about 0.80 in. higher under the conditions represented by Sec. 1 than those by Sec. 2, also that the temperature shown in Sec. 1 is about 25 deg. higher than in Sec. 2.

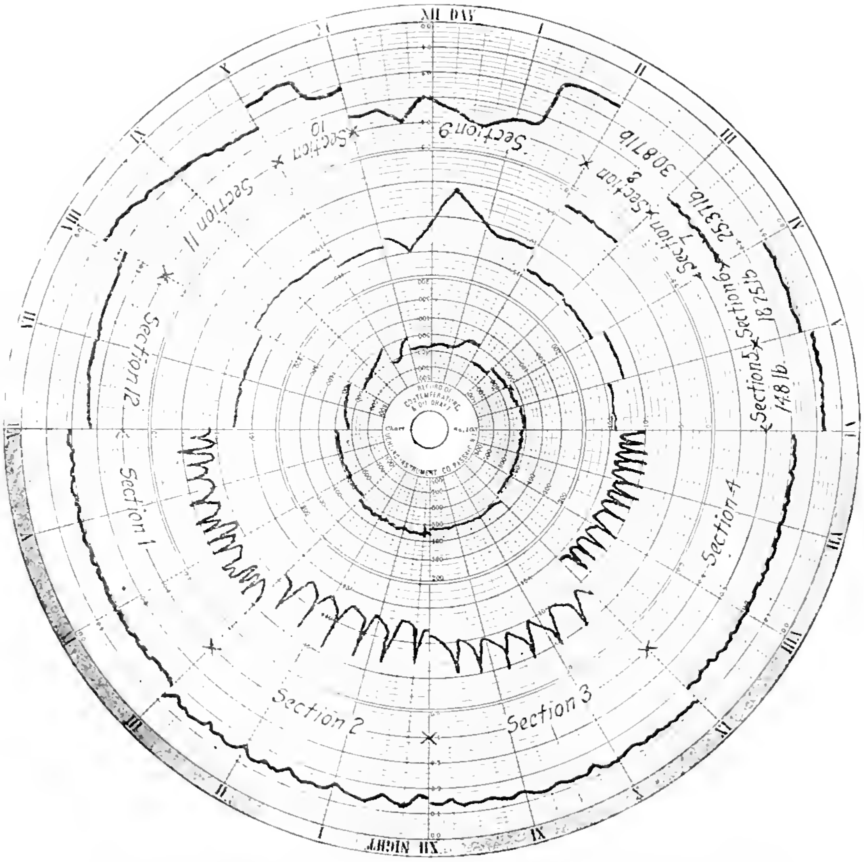

Fig. 1 Sections of Charts Recording CO_2, Stack-Gas Temperature and Boiler Draft

It will be noticed that the gases left the boiler at a temperature 25 deg. higher when containing 8 per cent of CO_2 than when they contained 12 per cent, which shows that absorption efficiency increases with combustion efficiency.

It will further be noticed that the boiler draft is about 0.12 in. with 12 per cent of CO_2 and fully 0.20 in. when only 8 per cent of CO_2 is present, which is due to the greater volume of gas per pound of carbon consumed.

Now since the boiler draft is an approximate index to the volume of gas produced per pound of carbon burned and CO_2 is a true index of the weight of carbon contained in this volume of gas, it follows that if we multiply the boiler draft by the percentage of CO_2, the product will be an approximate index to the rate of combustion. We therefore find that the indices to the rate of combustion under the conditions which are recorded in Secs. 1 and 2 were respectively $8 \times 0.20 = 1.60$, and $12 \times 0.12 = 1.44$.

This means that it was necessary to burn about $[(1.60 - 1.44)/1.44] \times 100 = 11$ per cent more coal to keep up the steam with 8 per cent of CO_2 than with 12 per cent, which corresponds very well with the improved results attained in the plant in which the records thus analyzed were produced.

Secs. 3 and 4 of Fig. 1 show records representing a water-tube boiler burning bituminous coal. Sec. 3 illustrates conditions before, and Sec. 4, after, control by aid of CO_2. A glance at the CO_2 record will show that the fires carried were too thick. The low percentage of CO_2 (about 8.75 per cent) was due principally to air infiltration, but to a considerable degree also to uneven firing producing high CO with low CO_2. Stopping up the air leaks and modifying the method of firing as illustrated by the record and using the CO_2 indicator as a guide, the fireman had no difficulty in maintaining an average of over 13 per cent of CO_2 with practically no CO.

Contrary to what was seen in Secs. 1 and 2 of the chart, both the temperature of the escaping gases and the boiler draft were higher when the conditions had been changed so as to result in the higher percentage of CO_2. This may at first seem contradictory; but a little study reveals the fact that both the boiler draft and the temperature of the escaping gases were rendered abnormally low by the flow of air (counter draft) entering through the leaky setting. It is therefore necessary to make sure that the setting is made tight before these two factors can be relied upon as indices, respectively, of absorption efficiency and rate of combustion. Furthermore, a low stack temperature cannot be relied on as an index to the former unless the gases contain a high percentage of CO_2.

In Secs. 5, 6, 7 and 8 of the chart are recorded the averages of four 24-hour tests of a large water-tube boiler burning bituminous coal fired by Roney stokers. The coal was burned at four different rates of combustion; viz., 16.7, 18.25, 25.3 and 30.8 lb. per sq. ft. of grate surface per hour. The CO_2 averaged 14.68, 13.05, 14.28 and 14.69 per cent; the boiler draft was 0.08, 0.12, 0.31 and 0.61 in. of water, and the temperature of the escaping gases averaged 483, 542, 662 and 636 deg. fahr., respectively. The efficiency attained was respectively 81.15, 77.45, 75.28 and 76.73 per cent.

These four tests demonstrate that the percentage of CO_2 can be maintained at its maximum irrespective of the rate of driving without increasing the percentage of CO, provided there is ample space for combustion. *A large combustion chamber is a most vital factor in securing combustion efficiency.*

Sec. 9 of the chart illustrates the relation the three records will take to each other if the demand for steam suddenly increases and the draft is adjusted to increase the rate of combustion to meet this increased demand, but the stoker is not speeded up sufficiently to supply the coal required. The flue-gas temperature will at once go up in response to the increased rate of combustion. The CO_2 will soon begin to drop, and if there is no CO_2 indicator

to show what is happening it will continue to drop until the fireman discovers that the grate is getting bare and the stoker speed must be increased. He does so, but gives it a little too much speed and the CO_2 goes above the safe limit. If he is a good fireman he will no doubt discover that also and finally get the right adjustment. Meanwhile considerable fuel has been wasted, first by excess air and then by incomplete combustion. With a CO_2 indicator to guide him this would not have happened.

Sec. 10 illustrates how the boiler-draft and pyrometer records will at once reveal the sudden breaking-down of a section of baffling. Sec. 11 shows how the average temperature and boiler draft would be affected if the baffling disintegrated gradually, and Sec. 12 indicates how the records would be likely to change if the boiler tubes were allowed to muck up gradually. These suppositious cases are given to show how the boiler draft and exit temperatures are affected by the same cause. Neither can be correctly interpreted without the other. Within practical limits of driving the maximum percentage of CO_2 can and should be maintained, whereas both the boiler draft and the exit temperature increase with the rate of driving. The exit gas temperatures vary from the normal from four distinct causes:

a Rate of driving
b Defective baffling
c Dirty heating surface
d Air infiltration.

The record of the boiler draft at once reveals the true cause; the pyrometer simply reveals the fact. Low exit gas temperature is generally taken to indicate absorption efficiency and the CO_2 record shows whether it is or not.

It thus appears that the three records, viz., percentage of CO_2, temperature of the escaping gases, and the boiler draft, autographically recorded, preferably on the same chart, reveal in detail all the facts necessary for effective control of the boiler operation. They give a continuous up-to-the minute history of the essential factors on which economic operation depends, and provide a ready means for interpreting the causes of irregularities and for applying the proper remedy promptly and intelligently. The three records being on the same chart, they can be quickly integrated by a polar planimeter and averaged, and thus form the best basis for a bonus system.

In addition to the three recording instruments, an Orsat apparatus is also essential—

a For determining the maximum per cent of CO_2 that can be carried without danger of an appreciable loss because of incomplete combustion
b To diagnose the boilers for air infiltration at regular intervals, or in between, if deemed necessary, and
c To check up the CO_2 meters when their indications give cause for suspecting their accuracy.

An Orsat is by itself quite inadequate as a control for the firing operations of a boiler plant, even when supplemented by sampling tanks, which combination, although better than nothing, cannot be considered more than a makeshift.

Formulæ for Calculating Heat Losses in Chimney Gases

It will now be shown how the information given by recording-instrument charts may be applied in computing the heat losses in detail. The following simple formulæ,[1] developed by the author, are based on a weight of fuel containing 1 lb. of carbon instead of on 1 lb. of fuel or combustible:

$$A_e = \frac{A_c \times 21}{P} - A_c \quad\ldots\ldots [1]$$

$$A_t = \frac{A_c \times 21}{P} = \frac{11.6 \times 21}{P} = \frac{243.6}{P} \quad\ldots\ldots [2]$$

$$L_d = (1 + A_t) S \times (T - t) \quad\ldots\ldots [3]$$

$$L_d = \left(0.24 + \frac{58.46}{P}\right) \times (T - t) \quad\ldots\ldots [4]$$

$$A_e = \frac{A_c \times 21}{P} - (A_c + N_h \times H_a) \quad\ldots\ldots [5]$$

$$L_d = \left(1 + \frac{58 + 46}{P}\right) \times (T - t) \quad\ldots\ldots [6]$$

$$L_c = 10{,}150 \times \frac{P_c}{P + P_c} \quad\ldots\ldots [7]$$

$$L_h = (8734 \times H_a) + (4.3 \times H_a)(T - t) \quad\ldots\ldots [8]$$

$$L_v = A_v\left(\frac{117}{P} + 3.8\, H_a\right) \times (T - t) \quad\ldots\ldots [9]$$

$$P_e = \frac{2100}{P(1 + 3\, H_a)} - \frac{(1 + 238\, H_a)}{1 + 3\, H_a} \quad\ldots\ldots [10]$$

$$P_o = 21 - (1 + 2.38\, H_a) \times P \quad\ldots\ldots [11]$$

$$P_m = \frac{A_c \times 21}{A_c + N_h \times H_a} = \frac{152 \times 21}{152 + 361\, H_a} = \frac{21}{1 + 2.38\, H_a} \quad\ldots [12]$$

Where

O = weight of oxygen per lb. of carbon in the fuel
H_t = weight of hydrogen per lb. of carbon in the fuel
$H_a = H_t - \frac{O}{8}$ = weight of available hydrogen per lb. of carbon in the fuel
A_c = weight of air required to burn 1 lb. of carbon
A_t = total weight of air supplied
A_e = weight of excess air supplied
N_h = weight of nitrogen in weight of air required to burn 1 lb. of hydrogen
A_v = weight of water vapor per lb. of air supplied per lb. of carbon burned
P = per cent of CO_2 in flue gas
P_c = per cent of CO in flue gas
P_e = per cent of excess air in flue gas
P_o = per cent of free oxygen in the gas
P_m = maximum theoretical per cent of CO_2 obtainable from any given fuel
$S = 0.24$ = specific heat of dry gases
T = temperature of gases on leaving the boilers, deg. fahr.
t = temperatures of air supplied for combustion, deg. fahr.
L_d = B.t.u. carried off by dry gas per lb. of carbon burned
L_c = heat value of CO contained in gas per lb. of carbon burned
L_h = B.t.u. carried off by H_2O produced by the combustion of the available hydrogen per lb. of carbon burned
L_v = B.t.u. carried off by water vapor in the air supplied to burn 1 lb. of carbon

Air contains	Per cent by weight	Per cent by volume
Oxygen....	23	21
Nitrogen..	77	79

One cubic foot of air at 62 deg. fahr. weighs 0.0761 lb.
One cubic foot of nitrogen at 62 deg. fahr. weighs 0.0742 lb.

Application of Formulæ to Data Derived from Autographic Records of CO_2

The usefulness and reliability of these formulæ are best shown by applying them to the data observed in a few authoritative boiler tests and comparing the results.

Tests A and B, Table 1, were made on a large boiler of the Stirling type rated at 2400 hp., equipped with forced draft and Roney stokers; the fuel was Pittsburgh coal. Tests C and D were made on a 210-hp. Heine boiler, hand-fired. The fuel was No. 1 Arkansas briquets in test C, and Illinois No. 3 coal in test D.

Dividing the weight of all the constituents of the coal by the weight of carbon per pound of fuel in order to reduce them to the carbon unit basis of 1 lb. gives the following values:

C	H	O	Ash	Moisture	B.t.u.
1.0	0.0683	0.1068	0.0925	0.023	17 984

The available hydrogen per pound of carbon is

$$0.0683 - \frac{0.1068}{8} = 0.055 \text{ lb.} = H_a$$

[1] The derivations of these formulae are presented in the complete paper.

TABLE 1 DATA AND RESULTS OBTAINED IN FOUR AUTHORITATIVE BOILER TESTS

Horsepower developed.......	2225	3606	206	201
Driving, per cent of rating ..	94	152	98.3	95.5

The water of hydration per pound of carbon is

$$0.1068 + \frac{0.1068}{8} = 0.12 \text{ lb.} = W_{hy}$$

From the data obtained in Test A, the heat carried up the chimney by the dry gases, according to Formula [3], is

$$L_d = \left(0.24 + \frac{58.46}{P}\right) \times (T - t)$$

Substituting the values of P, T and t,

$$L_d = \left(0.24 + \frac{58.46}{14.91}\right) \times (483 - 73) = 1706 \text{ B.t.u.}$$

Also, the heat value of the CO contained in the gas, according to Formula [7], is

$$L_c = 10{,}150 \times \frac{P_c}{P + P_c}$$

Substituting the values of P_c and P,

$$L_c = 10{,}150 \times \frac{0.023}{14.9 + 0.23} = 10{,}150 \times 0.0151 = 153 \text{ B.t.u.}$$

From Formula [8] the heat carried off by the H_2O from the combustion of the available hydrogen, is

$$L_h = 8734\, H_a + 4.32\, H_a (T - t)$$

Substituting the values of H_a, T, and t,

$$L_h = 8734 \times 0.055 + (4.32 \times 0.055 \times 410) = 578 \text{ B.t.u.}$$

Also, the heat absorbed by the humidity in the air, according to Formula [9], is

$$L_v = A_v\left(\frac{117}{P} + 3.8\, H_a\right) \times (T - t)$$

The average temperature of the air during the test was 73 deg. and the average humidity 62.4 per cent saturation. At this temperature and saturation the water vapor carried into the furnace is 0.0106 lb. per lb. of air supplied = A_v. Substituting this value and the values of H_a, P and $(T - t)$ in Formula [9],

$$L_v = 0.0106\left(\frac{117}{14.90} + 3.8 \times 0.055\right) \times 410 = 34 \text{ B.t.u.}$$

The heat carried by the water of hydration equals

$$L_w = W_{hy} \times (0.48\, T + 1080 - t)$$

Substituting the values of W_{hy}, T and t,

$$L_w = 0.12(0.48 \times 483 + 1080 - 73) = 149 \text{ B.t.u.}$$

Substituting the value of W_m for W_{hy}, where W_m is the weight of moisture per lb. of carbon, the loss due to the moisture in the coal is

$$L_w = 0.023(0.48 - T \times 483 + 1080 - 73) = 28 \text{ B.t.u.}$$

The foregoing comprise all the items of heat wasted up the chimney with the exception of that contained in the hydrocarbons, if any, and in the soot and ash passing off with the gases, and may be enumerated as follows:

Heat-Loss Items Up the Chimney

	B.t.u.
a Heat carried to waste by the dry gases..........	1706
b Heat value of CO..............................	153
c Heat carried to waste by the H_2O from the combustion of the available hydrogen..............	578
d Heat loss due to the humidity in air..............	34
e Heat carried to waste by the water of hydration...	149
f Heat carried to waste by the moisture in the coal..	28
g Total heat in H_2O in gases......................	789
h Total heat in flue gas per lb. of carbon burned (items *a*, *b* and *g*)..........................	2648

Hence $\dfrac{2648 \times 100}{17984} = 14.72$ per cent of the heat of the coal remained in the gases as they left the boiler.

The ash contained 31.6 per cent of carbon and since the coal contained 0.0925 lb. of ash per lb. of carbon, the loss due to the heat value of the combustible in the ash is

$$0.316 \times 0.0925 \times 14{,}600 = 427 \text{ B.t.u.}$$

which represents

$$\frac{427 \times 100}{17{,}984} = 2.38 \text{ per cent of the heat in the coal.}$$

The total heat loss accounted for by the preceding calculations is therefore

	Per Cent
Heat absorbed by boiler......................	81.10
Heat loss up the chimney.....................	14.72
Heat loss through the grate..................	2.38
Heat loss from radiation, etc................	1.80
Total.................................	100.00

The heat-loss items in Test A were reported as follows:

	Per Cent
Moisture in coal............................	0.16
Hydrogen in coal............................	4.29
Heat to chimney.............................	9.11
Moisture in air.............................	0.20
Carbon monoxide	1.29
Carbon in ash...............................	2.29
Total losses accounted for..............	17.34
Absorbed by boiler..........................	81.15
Radiation, etc.	1.51
Total................................	100.00

Applying the same formulæ to the observed data of Tests B, C and D, the results given in Table 2 are obtained.

Combustion efficiency in the operation of a boiler means only that all the combustible in the fuel must be completely oxidized, but that it must be oxidized in a manner that the maximum amount of the heat liberated becomes available to the boiler. Theoretically, all the heat liberated by combustion is available to the boiler except that contained in the gases below the temperature of the water in the boiler and the latent heat of the H_2O contained in the gases. Hence combustion efficiency so far as it is under the control of the fireman $= \dfrac{\text{Available heat liberated}}{\text{Heat available in fuel}}$.

Analyzing the results of these heat-loss calculations it is found that in Test A, $1706 \times 100/2648 = 64.12$ per cent of the heat up the chimney is carried by the dry gases, and that the heat value of the CO amounts to $153 \times 100/2648 = 5.78$ per cent. The remainder, or 30.1 per cent, is carried off by the H_2O from coal and air.

TABLE 2 RESULTS OF APPLICATION OF FORMULÆ TO DATA OF TESTS B, C AND D

	Test B	Test C	Test D
a Heat carried to waste by dry gases, B.t.u.	2560	3480	4853
b Heat value of CO contained in gases, B.t.u.	251	0	57
c Heat in H_2O from combustion of available hydrogen, B.t.u.	610	497	549

Total Heat Loss:			
Heat absorbed by boiler, per cent	75.78	65.39	60.32
Heat loss up the chimney, per cent	20.43	23.17	32.14
Heat loss in range grates, per cent	2.31	2.47	4.82
Heat loss from radiation, etc., per cent	1.48	8.97	2.65
Total	100.00	100.00	100.00
Losses in Test Report:			
Moisture in coal, per cent	0.17		
Hydrogen in coal, per cent	4.49		
Heat to chimney, per cent	12.79		
Moisture in air, per cent	0.36		
Carbon monoxide, per cent	1.95		
Carbon in ash, per cent	2.13		
Total loss accounted for, per cent	21.89		
Heat absorbed by boiler, per cent	75.78		
Heat lost in radiation, etc., per cent	2.33		
Total	100.00		
Heat Balance in Test Report:		Per cent	Per cent
Heat absorbed by boiler (= evaporation from and at 212 deg. per lb. of combustible)		62.33	64.20
Loss due to moisture in coal (= per cent of moisture referred to combustible)		0.09	0.96
Loss due to moisture formed by burning of hydrogen (= per cent of hydrogen referred to combustible)		3.28	4.18
Loss due to heat carried away by dry chimney gases (= weight of gas per lb. of combustible)		19.75	26.60
Loss due to unconsumed hydrogen, heating of moisture and unaccounted for		9.55	3.74
Loss due to incomplete combustion of carbon			0.32
Total		100.00	100.00

TABLE 3 ANALYSIS OF HEAT ESCAPING UP THE CHIMNEY

	Test A	Test B	Test C	Test D
(1) Per cent of heat up the chimney contained in the dry gas	65.20	69.66	86.40	84.02
(2) Per cent of heat escaping up the chimney represented by CO	5.80	6.83	0.00	0.98
(3) Per cent of heat escaping up the chimney due to H_2O	29.00	23.51	13.60	15.00
(4) Per cent of heat controllable in item (1)	27.00	48.43	69.40	78.26
(5) Per cent of heat controllable in item (2)	100.00	100.00	100.00	100.00
(6) Per cent of heat controllable in item (3)	8.50	7.80	11.20	7.50
(7) Per cent of controllable heat residing in the dry gas	85.20	94.90	97.40	98.70
(8) Per cent of excess air	23.00	29.00	97.00	160.00
(9) Per cent of free oxygen in gas	4.16	4.83	10.57	13.10

Since the gases cannot be cooled below the temperature of the water in the boiler, it is evident that only the heat contained in the gases above that temperature is under control of the boiler operation.

Applying Formula [12] it is found that the theoretical maximum percentage of CO_2 obtainable from the coal used in Test A is

$$P_m = \frac{21}{1 + (2.38 \times 0.055)} = 18.57$$

The temperature of the water in the boiler corresponding to the average steam pressure carried during Test A was 384.6 deg. fahr. Applying Formula [4], the uncontrollable heat in the dry gases per pound of carbon burned is found to be

$$L_d = 0.24 + \frac{58.46}{18.57} \times 384.6 = 1246 \text{ B.t.u.}$$

or

$$\frac{(1706 - 1246) \times 100}{1706} = 27 \text{ per cent}$$

hence only 27 per cent of the heat in the dry gases in this test was controllable.

The loss due to CO is independent of the stack temperature, and since the percentage of CO in the gas can be reduced to zero, the heat loss due to its presence is 100 per cent controllable.

Since the heat loss due to the H_2O in the gases is independent of the CO_2, only that portion is controllable which is affected by the temperature of the flue gas above that of the water in the boiler.

The latent heat of evaporation is not controllable, hence the terms in the formula representing it must also be eliminated. Thus, applying the modified formula to the observed data we have for the controllable heat in H_2O:

$$\left[4.32 \times 0.055 + 0.0106 \times \left(\frac{117}{14.9} + 3.84 \times 0.055\right)\right] \times (583 - 385) + 0.48 \times (583 - 385) \times 0.143 = 67.53 \text{ B.t.u.}$$

Since the total heat carried to waste by the H_2O in the gas is 798 B.t.u., it is seen that only $\frac{67.53 \times 100}{798} = 8.5$ per cent of it is controllable.

Of the heat in the dry gas $(1706 - 1246 =) 460$ B.t.u. were controllable, hence the total controllable heat escaping amounts to $460 + 67.5 = 527.5$ B.t.u., and of this $\frac{460 \times 100}{527.5} = 87.2$ per cent resides in the dry gases.

Table 3 gives the results of the foregoing calculations for the four tests under consideration. Item (1) shows what percentage of the heat wasted up the chimney is contained in the dry gas that can be controlled to a greater or lesser degree by improving operating conditions. Item (7) shows what percentage of the controllable heat resides in the dry gases. All of which emphasizes the importance of the CO_2 and temperature records, as controlling factors in boiler operations.

The fireman must drive his boilers in accordance with the demand for steam. He has no control over the condition of the heating surface of his boilers. And since the temperature of the escaping gases depends primarily on one or both of these conditions it is not fair to him to judge his proficiency by heat wasted up the chimney, and much less fair is it to judge him on the basis of pounds of water evaporated per pound of coal burned. In Test A, for example, there was 10 per cent more water evaporated than in Test B, while the difference in furnace efficiency based on heat available was only 2.1 per cent, as demonstrated above.

The proper basis upon which to judge the proficiency of a fireman is the factor $0.24 + \frac{58.46}{P}$ after the maximum percentage of CO_2 (P) with practically complete combustion has been established for the prevailing conditions at any given plant.

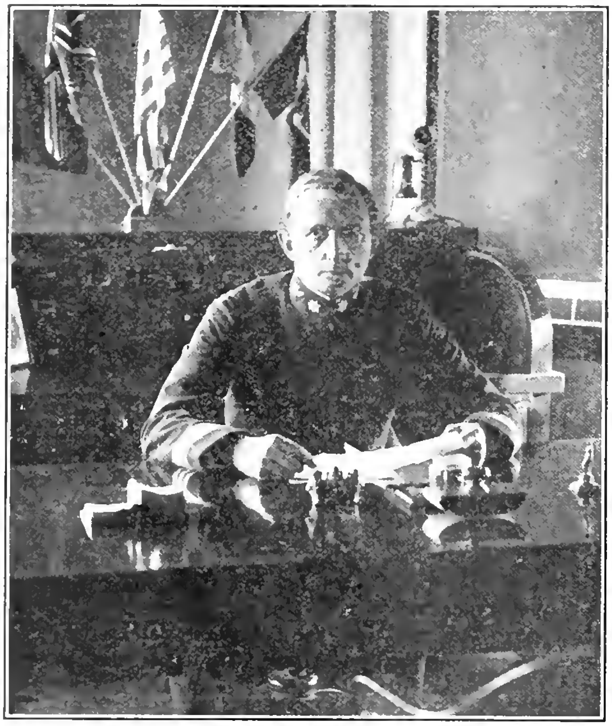
Within proper limits of CO_2 there exists no relation between the percentages of CO_2 and CO. Test B, for example, shows 0.7 per cent less CO_2 and 0.13 per cent more CO. Furthermore, it must be borne in mind that the loss due to the same percentage of CO diminishes directly as the percentage of CO_2 increases, as is shown by the factor $\frac{P_c}{P + P_c}$. It is a matter of easy calculation

(Concluded on page 199)

THE NAVAL AIRCRAFT FACTORY

IN his strikingly interesting lecture on the engineering achievements of our Navy in the war, given at the Annual Meeting, Lieut.-Commander Cathcart limited himself to a recital of the work of a single bureau of the Navy Department—the Bureau of Steam Engineering.[1] "The work of this bureau," he said, "should be regarded as but a sample of what all the bureaus of the department have done. From the beginning of the war the entire Navy Department has been working in a clean-cut American way, at maximum efficiency under forced draft."

One of the most noteworthy of its accomplishments—that of another bureau—has been the construction and organization of the great naval aircraft factory at the League Island Navy Yard, Philadelphia, and the bringing it up to quantity production in 10



Commander F. G. Coburn, Manager, Naval Aircraft Factory

months from the time work on the first building was started. It was a pioneer undertaking, attended by innumerable difficulties, which, however, were but the measure of the possibilities that it was hoped might be realized. That they were actually realized is attested by the fact that from the first the factory has been ahead of its schedule.

On July 27, 1917, Secretary Daniels authorized the construction of a government-owned aircraft factory. The site selected was a 40-acre tract of pasture land at League Island, entirely undeveloped. The original manufacturing unit was a permanent steel structure having a ground area of 160,000 sq. ft., built and equipped in three months and put in operation before the final touches had been given to the structure.

Early in January 1918 the Navy's aircraft program was expanded far beyond the manufacturing facilities of this original building and plans were developed for the enlargement of the plant to four times its original size. The augmented program required new aircraft faster than they could be provided by building an entirely balanced factory. The authorization therefore contemplated that the new extension should be an assembly plant and in proportion to its growth, privately-owned manufacturing facilities be taken off their regular commercial work and placed under contract to furnish the hulls, wings and other parts needed. Thus branches of this establishment appeared in many places throughout the East which turned their activities to a common end under the direction of the Naval Aircraft Factory.

When the armistice was signed the enlarged plant comprised, besides the original building, 400 ft. square, the new Plant No. 2, over 1000 ft. long, with a high assembly shop 200 ft. wide for the largest types of aircraft, and a one-story ell 350 ft. wide; a storehouse 200 by 175 ft.; administration building 180 by 125 ft.; lumber storage and dry kilns; boiler house; hangars, etc., comprising 25 acres of floor space and a capacity of four seaplanes per day.

At this time 3740 men and women were employed at the factory, besides 8000 by outside contractors.

The chronology of this extensive development is as follows:

July 27, 1917, Secretary Daniels authorized construction.
August 10, construction work began.
October 16, first machinery started.
November 2, first keel laid.
November 28, first plant completed.
January 25, 1918, expansion of plant ordered to four times original size.
March 27, first service machine completed.
June 1, full designed production of first plant attained.
November 4, 1918, production of two completed hulls a day and plant capacity sufficient to produce four machines a day.

In view of the special character of the undertaking, in what in this country was a little-understood field, this record of progress is in many ways unprecedented. As a patriotic accomplishment on a vast scale, it is one in which the Navy Department may well take pride; and as an example of efficient organization and able able administration it must be classed as a real achievement.

Commander F. G. Coburn, Manager

The manager selected for the undertaking, and who has so successfully carried it through to completion, is Commander F. G. Coburn, Mem.Am.Soc.M.E., who was previously stationed at the Boston Navy Yard. Members of the Society will remember the comprehensive paper presented by Commander Coburn at the Annual Meeting three years ago, on the heat treatment of wrought iron, a subject at that time but little understood. This gave the results of an elaborate investigation for the purpose of improving the strength and reliability of heavy anchor chain forged at the Boston Navy Yard for the U. S. battleships.

Commander Coburn is a graduate of Annapolis and of the Massachusetts Institute of Technology, where he qualified as a naval architect and marine engineer, with the degree of Master of Science. He served one year as a line officer in the Asiatic service, and had some 10 years' industrial experience in several of the navy yards of the country, where he became interested in scientific management and gave considerable time, also, to investigations of the methods of civil industrial plants. All of this experience, as well as initiative, visions and the ability to undertake new and great things had ample opportunity to come into play in the new project upon which he embarked.

Organization of Staff and Working Force

It is coming to be generally recognized that in any manufacturing enterprise the personnel is the most essential element. Buildings can be erected and machinery purchased, but to do effective work an organization must be built up with infinite pains and its methods of work in the different departments carefully coördinated.

What shall be said, then, of a project such as this, where the organization had to be formed at the very start, with no time for experimenting, and in a field where there were practically no men experienced in the art upon whom to draw; for what few there were in this country who had had any experience in aircraft production were already in war work in other aircraft factories.

The executive staff was first got together, selected by Manager

[1] See Mechanical Engineering, January 1919, p. 18

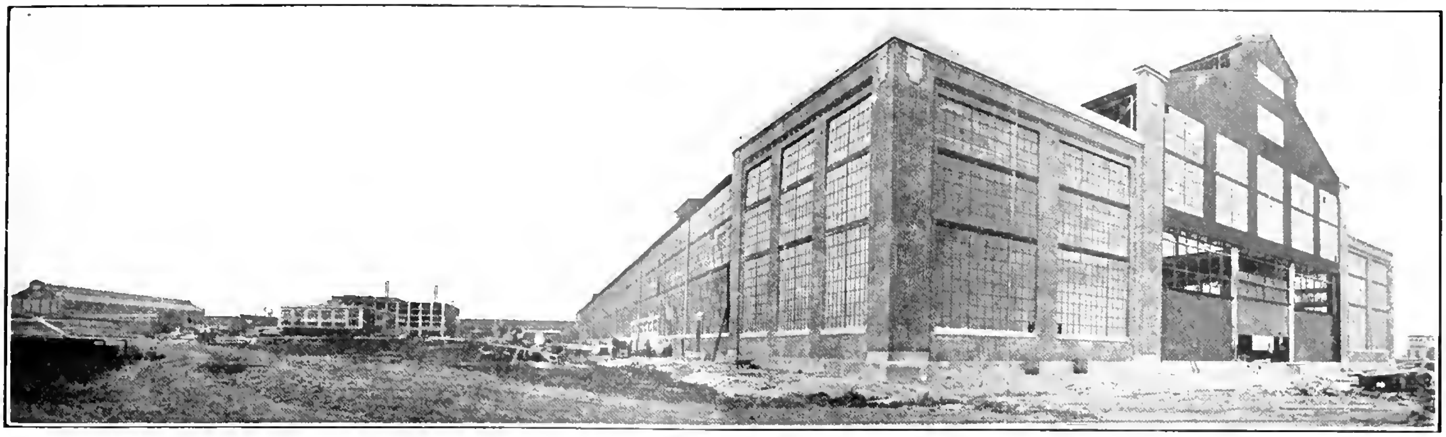


FIG. 1 PANORAMIC VIEW OF NAVAL AIRCRAFT FACTORY; ORIGINAL PLANT AT EXTREME LEFT, NEW ASSEMBLY SHOP AT RIGHT, ADMINISTRATION BUILDING AND STOREHOUSE IN THE CENTER

Coburn from civil life, as the Navy could spare but one more officer, Lieut.-Com. F. J. Daly, Pay Corps, who became Supply Officer.

Upon the employment department fell the problem of supplying man power for the factory. Civil Service rules and the regulations of the Navy had to be taken into consideration at every step. Testimony to the generally satisfactory caliber of employees secured under Civil Service, however, is found in the fact that it was necessary to hire a total of only 6035 persons to provide for the nearly 4000 at work at the cessation of hostilities and only 139 had been discharged for cause.

The story of the building up of the force is full of interest. The hulls of the seaplanes were the most difficult parts to construct and boat builders were essential, but where were they to be found with the Emergency Fleet Corporation in operation, and supposedly using every available shipbuilder? A representative of the Naval Aircraft Factory went to the Jersey coast, however, and prevailed upon nearly 80 boat builders to leave their own personal work and come to the factory to "do their bit" in helping to put the U-boat out of commission. Among them were old boat builders who owned shops near their homes and who consented to close their doors for the time being and join forces in the new undertaking. One of these was the newly-elected mayor of the small city in which he lived. Trained by long experience to do all of a job, these men readily fitted into the aircraft work after a brief course of instruction at the factory school.

Specialists in aircraft production were picked up here and there, often by chance, for other parts of the work. A Belgian soldier and former aviator who had escaped from a German prison camp, applied in person, specifying in his enthusiasm that he should work not less than 12 hours a day. A French infantryman who had previously studied motor construction in this country and was wounded at the front, returned to America, learned of the League Island factory through the War Community League at one of the Philadelphia railroad stations, and secured an important position there. And so, little by little, but nevertheless with rapidity, the force was built up and placed effectively at work.

EMPLOYMENT OF WOMEN

From its inception, the Naval Aircraft Factory employed women for clerical work and in December 1917 they were first used in the Inspection Department, to inspect screws, bolts, turnbuckles and small metal parts. This work required accuracy, good judgment and common sense, but very little previous experience or training. In order that their services might be extended to other departments where previous experience and special skill were required, a training school for women was started in May 1918. The women are placed in this school when employed, where they are given training in factory processes. They are here tried at various kinds of work and are then trained to do the thing for which it is observed they are best fitted. This is determined by a daily record of the work of each woman for one month, whose grade of work and adaptability for that work are discussed with her immediate superior; and everything possible done to make her contented and efficient.

At the close of the war activities 900 women were employed in the factory, most of them having come through the training school, equipped to serve capably in many of the departments of the works. In the mill they are employed on the spruce layout, on band saws and molding machines and as helpers. In the hull cover department they help with parts of the hull cover and also construct alone small parts, such as gun mounts and access doors. They are employed exclusively in jigging, reinforcing and sandpapering the webs preparatory to their use in the panel, or wing, assembly. In the panel shop they are used to a great extent in the construction of elevators, rudders, stabilizers and

panels of all types. They then cover these parts with linen or cotton fabrics preparatory to their going to the dope room.

In the machine shop, women operate the drill presses, wrap, solder and splice wires and cables; and file and weld metal parts. In the pontoon department they help construct the wing floats; and in the boat shop they help in planking the hulls and perform small operations in hull and final assembly. Women are used to a great extent in the storerooms and tool cribs. They are used in drafting and operating the blueprint and photostat machines and also some testing machines in the engineering department.

It is interesting to note that the factory has three forewomen who have "made good" and accomplished much in expediting production.

The women work the same hours as the men, i.e., 49 hours a week, making a 9-hour day during the week and a half-day of 4 hours on Saturday. They are paid on an 8-hour basis and make time and a half for overtime and Sunday work. The factory is operated on the plan of equal pay for equal work and when a woman is able to equal the output of the men she receives the same pay. In most cases, however, the women have not yet had sufficient experience, or are not able physically to reach such an output and receive correspondingly less wages.

The working conditions are made as favorable as possible for the health and comfort of the women and particular attention was paid to this so that in spite of long hours and unusual exertion they might be able to hold their own during the period of the war with no bad post-bellum results. Necessarily the work is tedious and hard for many. They must rise early, commute long distances, walk a mile to the factory from the Navy Yard gate, and work nine hours. Nevertheless, they have done it faithfully and patriotically, making their contribution in this way to the great cause of freedom.

Contract Work

The great number of seaplanes to be constructed, and the early date set for their completion, made the building of them all in a single plant an impossibility. Not only was the time too short for the erection of the necessary buildings, but the matter of training the many workmen required would occasion a delay beyond the time allowed.

The full capacity of the Naval Aircraft Factory was therefore determined and every unit entering into the construction of hulls and wings that could be built in the plant was retained as its quota of the production program. It was decided to contract with such factories as were fitted to do the work for the balance of the program.

For this purpose, a new department was organized, termed the Contract Manufacturing Department, having as its function the distribution of work to sub-contractors. A conference between departments resulted in a schedule being compiled of all the seaplane elements which were in excess of the Aircraft capacity, such parts to be procured outside.

A careful survey was made of all plants capable of handling the work with the idea of giving each one the quantity of work it could complete by the time the entire program must be finished. Only such plants were considered as were equipped with the necessary machinery and positive assurance was required that the requisite number of skilled workmen was immediately available. By placing contracts in this way an economy in time and cost was made possible, as each plant became a specialist in the construction of its particular unit.

A number of well-equipped and reputable yacht-building concerns were awarded contracts for the construction of the boat hulls. Smaller boat shops, furniture and cabinet factories were awarded contracts for the building of panels (wings) and tail surfaces. The metal fittings, of which there are thousands, were awarded to shops equipped with modern automatic machinery and the necessary heat-treating apparatus. As previously stated, about 8000 people were engaged in the outside manufacture of these parts, which were shipped to the Aircraft Factory and there assembled.

The Engineering and Other Departments

A vital part in the successful production of the factory has been the large and well-organized Engineering Department under the direction of the Chief Engineer, Major G. R. Wadsworth of the Signal Corps. This is made up of the following divisions:

Experimental, comprising construction of new parts, material and types; assembly and erection; testing plane and engine performance and accessories.

Design, embodying inventions; experimental design; cost estimates; records and issues; production drafting, blueprinting, etc.

Specifications and Intelligence, covering technical data from periodicals and other sources; specifications of materials and processes; instruments, accessories, performance, etc.

Inspection, comprising inspection of materials at source; in stockroom; in process of manufacture; and inspection during erection, final acceptance test, and packing.

Testing, chemical and physical, metallurgical, strength of materials.

Trials of completed planes; besides several other divisions, such as *Engineering Service*, *Wood Technology* and *Photographic Work*.

The responsibilities resting on this department are very great because of the combination of strength and lightness required in aircraft, and the almost infinite care which must be exercised to secure both workability and safety. Skill in design and alertness in inspection are both vital. A staff of 125 inspectors is required for the work of inspection.

A department known as the Manufacturing Office receives the requirements of the Navy Department and accumulates all necessary data for the requisition of materials, issuance of orders to all factory departments and the scheduling of work and equipment. The clerical work of production is concentrated here to leave the executives of the manufacturing departments free for the closer supervision of actual production.

The Contract Manufacturing Department has the responsibility of keeping the large assembly plant going to capacity by supplying the component parts of the finished product for final assembly. The Supply Department uses every means of rapid transportation for the earliest possible delivery. In each of the subsidiary shops doing contract work is stationed a representative from the main factory who acts as branch manager and is responsible for results.

Standardized Seaplane

The standard seaplane manufactured at the Naval Aircraft Factory is of the flying-boat type, equipped with two Liberty motors and having a speed of 100 miles an hour and a cruising radius of 10 hours. It carries five men, four machine guns, four bombs, 500 gal. of gasoline, wireless and other equipment and weighs, with its crew, about 14,000 lb. The construction of the panels or wings, built up of a skeleton of spruce webs and piano-wire braces, is familiar to all. The webs are but 1/4 in. thick, cut out in the center and ends, and braced by small battens, less than 1/16 in. thick, which are stapled to them. Similar construction, but heavier, is followed in the boat. Tubular steel struts and tension wires reinforce the entire structure. Multiple-ply veneer less than 3/16 in. thick is used for planking. The prototype of this flying boat was the *America*, built for Mr. Rodman Wanamaker by the Curtiss Aeroplane Co. before the war for a transatlantic flight; the war broke out before the flight was attempted.

It is not the purpose of this article, however, to describe the details of construction of naval aircraft, nor to consider the intricate processes of manufacture; but rather to place on record a noteworthy accomplishment in industrial development for the prosecution of the war. The accompanying illustrations tell their story of the extent of the plant and of the volume and complexity of the work in process. L. G. F.

The first of a series of instructive bulletins on Employment Management has recently been issued by the United States Shipping Board, Emergency Fleet Corporation.

THE PATENT SITUATION IN THE UNITED STATES

AT the meeting of the New York Section held January 14, 1919, a paper was presented by Edwin J. Prindle, Mem.Am.Soc.M.E., on the Patent Situation in the United States which reviewed the recent movement to increase the efficiency of the Patent Office. Mr. Prindle is a member of the Patent Committee of the National Research Council appointed at the request of the Commissioner of Patents with the approval of the Secretary of the Interior, to investigate the Patent Office and the patent system, with a view to making recommendations for improvement in this department of the Government and in the patent system as a whole.

Since his paper was presented, the report rendered by his committee has been approved by the Commissioner of Patents, by the National Research Council and by the Engineering Council and has been released for publication. The substance of the report has been incorporated in what follows, with a preliminary explanation taken from the introductory portions of Mr. Prindle's paper. In connection with the report, it should be stated that three bills have been drafted to be presented to Congress during the early part of its next session, with the expectation of putting into effect the provisions of the report.

Introduction By Edwin J. Prindle

Various events make the patent situation in the United States of especial interest at this time. The exceedingly important part played by inventions in the war has shown the desirability of increasing the incentive to produce inventions. The intense competition which will come from the strivings of the debt-laden countries of Europe to rehabilitate themselves will result in every possible effort to stimulate their own inventors, and this will make it necessary that we see to it that our inventors have the fullest incentive consistent with a sound policy. A movement is already on foot, seeking to improve the efficiency of our Patent Office and patent system and which, directly and indirectly, will improve the inventor's position.

The present movement seeking to increase the efficiency of the Patent Office and of the patent system was started by the Society of Patent Office Examiners, at whose request the Commissioner of Patents, with the approval of the Secretary of the Interior, asked the National Research Council to appoint a committee for the purpose of investigating the Patent Office and patent system and making recommendations to those ends.

The reason for asking the National Research Council to undertake this work was that the Council is a body of such high scientific standing and so free from any suspicion of a bias or selfish interest in the subject that its recommendations would be likely to have the maximum weight with Congress for any legislation which should become necessary.

The National Research Council complied with the request and appointed a committee consisting of Dr. William F. Durand, Chairman; Drs. Leo H. Baekeland and M. I. Pupin, scientists and inventors; Drs. R. A. Millikan and S. W. Stratton, scientists; Dr. Reid Hunt, physician; and Messrs. Frederick P. Fish, Thomas Ewing and myself, patent lawyers. I was appointed as the representative of this Society. On the departure of Dr. Durand for Europe, Dr. Baekeland was appointed Acting Chairman of the committee.

This Patent Committee has made a report to the National Research Council, accompanied by carefully drafted bills ready to be introduced into Congress if the report is approved.

The United Engineering Society also appointed a Patent Committee for the same general purposes as that of the National Research Council and instructed it to coöperate with the Committee of the National Research Council and with committees of other technical societies organized for a kindred purpose.

Dr. David S. Jacobus and I were designated to represent The American Society of Mechanical Engineers on the Patent Committee of the United Engineering Society. The American Society of Civil Engineers is represented by Messrs. C. A. P. Turner and Leonard Metcalf; the American Society of Mining Engineers by Messrs. J. Parke Channing and Horace P. Winchell; and the American Society of Electrical Engineers by Messrs. Charles A. Terry and Frank N. Waterman. Mr. Terry is chairman of the committee.

REPORT OF PATENT COMMITTEE TO THE NATIONAL RESEARCH COUNCIL

THE Committee has concluded to propose a program consisting of but four features, because it believes those features are of such fundamental importance that their enactment into law would strengthen the entire system and directly and indirectly establish it upon a new and much more advantageous footing before Congress and the public; and because with a simple program, presenting comparatively little opportunity for difference of opinion as to the desirability of the changes proposed, there would be an unanimity of opinion in support of it which could not be obtained if the program were more extended.

A Single Court of Patent Appeals

The first proposal which your Committee recommends is the establishment of a single Court of Patent Appeals that will have jurisdiction of appeals in patent cases from all the United States District Courts throughout the country, in place of the nine independent Circuit Courts of Appeals in which appellate jurisdiction is now vested.

Until 1891 the Supreme Court of the United States was the appellate court in patent cases for all the lower courts. At that time the right of appeal to the Supreme Court in patent cases was taken away, and that Court now hears patent cases only upon writs of certiorari, which are never granted unless certain very unusual conditions exist.

The existence of nine appellate courts of concurrent jurisdiction in patent cases works serious hardships. While, theoretically, the law is the same in all of these courts, there has been an irresistible tendency to drift apart in the application of the law. It has even happened in a substantial number of cases that two of the appellate courts have taken a different view of one and the same patent. It is, of course, very important that the questions which always exist as to the validity and scope of a patent should be settled once and for all at the earliest possible date in the life of the patent, for, as a practical matter, 17 years (the term of a patent) is a comparatively short time in which to reduce the invention to a thoroughly commercial form, to prepare for its manufacture, and to introduce it upon the market, and it is usually necessary to determine the validity and scope of the patent in order to determine the amount of money which it is safe to invest in exploiting the invention. As things are now, whichever party succeeds in the first suit that is tried on the patent, the other party is very likely to feel that in a second trial before another court he might have better luck. He, therefore, is inclined to insist upon a second litigation. Meantime, he advertises that the questions involved were not settled in the first case. This means uncertainty on the part of the owners of the patent as to their rights and uncertainty on the part of the public as to its rights to use the invention or to determine what it must avoid in working in the same field—a really intolerable situation.

Moreover, we shall never have a uniform and definite patent law, consistently applied, until we have a single Court of Patent Appeals independent of local sentiment, realizing a responsibility to fix the principles of the law and enforcing an harmonious application of these principles on the lower courts. It would be of the utmost value to those in the United States who are engaged in industry if the present confused condition could be corrected and a single tribunal created to devote itself to crystallizing the fundamentals of the patent law and to educating the courts throughout the land to uniformity in applying these principles in special cases.

The increased expense due to such a court would be small. The aggregate amount of work to be done by the Judges of the United States Courts as a whole would not be changed to any substantial extent, because all appeals must now be heard by the present courts and Judges and, if there were a single Court of Patent Appeals, the Courts of Appeal in the nine circuits would be relieved of just as many appeals as were heard by it. The Judges in some of the circuits are much overworked, but this is not true of many of the circuits. The Chief Justice of the United States Supreme Court, in selecting these Judges, could, if he chose, take into account the work of the different circuits and whether one circuit or another could best spare a Judge.

As the law now stands, Judges from one circuit may be called upon, and not infrequently are called upon, to go into other circuits which are short-handed. In this way, any undue pressure upon the Judges in any particular circuit, by reason of the loss of any single Judge who went to the Court of Patent Appeals for six years, could be relieved.

A further advantage is that a single Court of Patent Appeals would see clearly where there were defects in the statute and in the conditions and practice in the Patent Office, and could speak with authority on all matters which affect the theory and practical working of the patent system.

The Patent Office a Separate Institution, and Independent of the Department of the Interior

The second proposal which your Committee recommends is that the Patent Office be made a separate institution, independent of the Interior or any other department.

The Patent Office was originally in the State Department, but, on the formation of the Interior Department in 1849, it was made a bureau of that Department and has been so ever since.

The only matters connected with the Patent Office with which the Secretary of the Interior has anything to do are the following: The Secretary of the Interior must submit to Congress all estimates for appropriations. All appointments, excepting those of the Commissioner, two Assistant-Commissioners, and five Examiners-in-Chief, are made by the Secretary but only on the recommendation of the Commissioner. The eight places named are Presidential appointments, but the Secretary makes recommendations to the President. All matters of disbarment or reinstatement after disbarment of attorneys are passed upon finally by the Secretary. All matters of discipline are under the Secretary's jurisdiction. The Secretary of the Interior must approve all changes in the Rules of Practice of the Patent Office, but he cannot compel the commissioner to make any change whatsoever.

No appeal lies to the Secretary from any decisions of the Commissioner, either in matters of merit or practice. All such matters, as far as they are reviewable, rest with the courts of the District of Columbia.

The Secretary of the Interior no longer signs the patents, and has no jurisdiction to grant or refuse them.

Thus it will be seen that the Secretary of the Interior is not required to know anything about patents or patent law. He is not selected because of any qualifications for the granting of patents or supervision over the Patent Office. The Secretary of the Interior has less influence over the Patent Office than over any other bureau of the Interior Department, because there are appeals to him from all the other bureaus. Nor is the Patent Office related to any other bureau of the Interior Department.

The Secretary of the Interior has recently moved out of the Patent Office building, thus severing physical contact with the Patent Office, which is but a type of the lack of mental contact between the office of the Secretary of the Interior and the Patent Office.

The experience of many Commissioners over a period of several generations has shown that, no matter how pleasant the personal relations may be, the Commissioner of Patents cannot expect any real benefit to the Patent Office to flow from its connections with the Interior Department. There is nothing in common between the interests of the Interior Department and those of the Patent Office, and, consequently, nothing to produce any advantage from the amalgamation of the Patent Office into the Interior Department.

Your Committee believes that to make the Patent Office an independent bureau would greatly increase the respect of the public and Congress and the courts for it, and would make it easier to procure enlarged appropriations and better salaries than under present conditions.

As to appropriations, under present conditions the demands of the Patent Office for equipment, personnel and salaries are necessarily subjected to comparison both by the Secretary of the Interior and by Congress with those of several other unrelated bureaus, each pressing its own demands and criticising any apparent preference. In the opinion of your Committee, this operates as a severe handicap. In estimating the needs of the Patent Office, there should be no discussion of the demands, for example, of the Pension Office or the General Land Office. As an independent institution, the needs of the Patent Office would be judged on their necessity and the appropriations be determined by considerations of general policy.

As to personnel: The enhanced dignity and independence of the Patent Office would render all positions of importance in it more attractive, and particularly would make it easier to secure and retain in office men of the necessary qualifications to fill the difficult office of Commissioner.

Increase in Force and Salaries of the Patent Office

The third proposal which your Committee recommends is a substantial increase in the force and salaries of the Patent Office. The patents granted by the United States Patent Office are of less average probable validity than formerly, because the number of applications for patents and the field of search are constantly increasing, while the examining force for many years has been insufficiently large and has not been increased proportionately. The inducements are so unattractive that 25 per cent of the examining force has resigned within the past three years. Your Committee finds that the Patent Office is suffering both from lack of examiners and from inadequate compensation.

The salaries of the Patent Office examiners have been increased only 10 per cent since they were fixed in 1848, when they were approximately the same as those of members of Congress. At the time the salaries of the Examiners-in-Chief were fixed, they were the same as those of Federal District Judges. During the past 70 years, the compensation for technical service in almost all other directions has been increased very largely. Congress, in creating new positions, is willing to pay technical men salaries more nearly approximating the usual compensation of such men in private service, but, having started a position at a given salary, is very loath to increase the salary. A Principal Examiner, to pass the entrance examination for the Patent Office, must himself have an education equivalent to that of a college graduate, and yet his salary is so low ($2700 a year) that it is practically impossible for him to give his own sons a college education.

Your Committee believes that salaries should be paid to the examiners proportionate to those paid for equally high technical work in other departments created recently; such, for example, as are paid in the Army and Navy and in the office of the Attorney General. The examiners are passing upon questions often involving millions of dollars, and they cannot be at their best in this vitally important work unless their salaries are large enough for them to live comfortably and without strain. The chances of making mistakes in the granting of patents are great enough even under the most favorable circumstances, and they should not be increased by compelling the examiners to work for inadequate salaries. The inducements should be such as to present compensation and a career which would attract and hold men of the highest ability. The payment of adequate salaries and the creation of provisions tending to hold out attractive prospects to the examiners would also tend to raise the dignity of the Patent Office and to increase its standing in the estimation of the public and of Congress and the courts, and so would tend to enhance the value to the public of the patent system.

The work of the Patent Office has grown so much more rapidly than has the examining force that the examination to determine whether or not the invention claimed in an application for patent is novel is imperatively restricted to the field of search where it is most likely that the invention will be found. Many patents are granted which would not be granted if the examiner had time to make a thorough search. One of the Assistant-Commissioners of Patents is compelled to devote a large amount of his time to speeding the work of the examiners in order to prevent further falling behind in the number of unexamined cases. Money is often invested on the strength of patents, only to find later that the patent is upset in the courts, because the Patent Office search did not go far enough to discover that the invention had already been disclosed in some earlier patent or publication. The granting of a patent with invalid claims or claims which are too broad or which are nebulous is a menace to the art to which it relates, and until such a patent has been adjudicated and its effect judicially determined, it tends to prevent manufacturing and commerce in that art. Such a patent may, in this way, cost the public many millions of dollars beside the cost of establishing its invalidity or its true breadth or meaning by litigation, and the prevention of the granting of such patents by any reasonable increase in the examining force of the Patent Office would, in many cases, be a very large saving. The inducement to inventors and investors in patents is consequently lessened, the standing of patents before the courts and the public is impaired, and the production of inventions discouraged.

Your Committee accordingly recommends a substantial increase in the salaries of the Patent Office officials, and in the number and salaries of the examiners, as provided in the draft of a bill for that purpose.

While your Committee believes the Patent Office so fully justifies its existence that it would be an exceedingly profitable investment, even though all expenses were paid from the public income, the Patent Office has always been self-supporting and the increase in salaries and examining force which the Committee recommends can easily be entirely taken care of by the Patent Office income, if necessary.

Compensation for Infringement of Patents

While an injunction can ordinarily be obtained against an infringer in a case where a patent is adjudged valid, except where it would interfere with Government work, a money recovery has not heretofore been generally possible except under most favorable circumstances. In a case where it cannot be said that the entire salability of the article depends upon the invention, it has been necessary to show just how much of the price of the article is attributable to the invention, and as it is ordinarily impossible to make such a separation, and as most patent cases are ones in which it cannot be said that the whole salability of the article depended upon the invention, it has resulted that recovery of money is seldom obtained in a patent suit.

Recently there have been two or three decisions in which the courts have taken a more liberal attitude, holding in effect that where an invention has been used by an infringer a reasonable royalty may be awarded to the patentee based on a mere estimation or on opinion evidence, even though no exact computation can be made. This is analogous to the attitude of the courts in personal injury cases and is entirely just and reasonable. While, as stated, there have been two or three decisions to this effect, it may take a generation to induce United States courts generally to adopt this position, if at all, and the Committee therefore proposes that the law be amended to provide, that as damages to the complainant, the court, on due proceedings had, may adjudge and decree to the owner payment of a reasonable royalty or other form of general damages. Such an amendment has been provided in the bill amending Section 4921, the Revised Statutes of the United States, and reading as follows:

"If proof is not offered or, in the absence of adequate proof of the amount that should be awarded as damages or profits, the court, on due proceedings had, may adjudge and decree to the owner payment of a reasonable royalty or other form of general damages."

This proposed amendment would enable the patentee in all suits where the patent has been found valid and infringed to recover at least a reasonable royalty, and would provide a money recovery in the great majority of patent suits where no recovery would otherwise be possible. The Committee believes that the comparative certainty of financial return would answer one of the most common and strongest reproaches against the patent system, namely,—that a patent does not ordinarily pay the inventor any money, and it believes that the incentive to invent would accordingly be greatly increased.

There are some cases in which it seems to many who are familiar with such matters as though the courts were inclined to go to the other extreme and award damages out of all proportion. Where a complainant has shown that profits have been made by the use of an article patented as an entirety, the infringer is liable for all the profits unless he can show—and the burden of proof is on him to show—that a portion of them is a result of some other invention used by him. If the infringer cannot show what proportion of the profits is due to such other invention, then all his profits must go to the complainant. Any rule by which the entire profits are given to a patentee in the absence of proof that they are all due to the invention of the patent sued upon, is unfortunate and sometimes very unjust. The proposed amendment to the statute would permit a court under these circumstances to do substantial justice even though it could not be mathematically exact. In other words, the amendment to the statute would enable a court to avoid awarding either too much or too little.

Conclusion

Your Committee, believing that the American Patent System is vitally useful in our system of Government, therefore recommends that the reforms herein discussed be enacted into law.

Your Committee also recommends that this report be approved by the National Research Council and that the Committee be continued for the purpose of arousing and coördinating interest in and support for the necessary legislation of various national societies, manufacturing interests, bar associations and other elements of the public.

Respectfully submitted,

L. H. Baekeland, *Acting Chairman*
William F. Durand, *Chairman* (absent in France)
M. I. Pupin
R. A. Millikan
S. W. Stratton (see reservation below)
Reid Hunt
Frederick P. Fish (see reservation below)
Thomas Ewing
Edwin J. Prindle

Approved by James T. Newton, *Commissioner of Patents*; by the National Research Council; and the Engineering Council. (See reservation in the Addendum, page 199.)

The reservation indicated above by Dr. Stratton is in respect to the establishment of the Patent Office as a separate Government institution. He is not convinced that this would be the best thing to do, since in general it is best for all Government establishments to be represented in the Cabinet.

The reservation by Mr. Fish calls for the omission of the words "if proof is not offered, or" in that portion of proposed Amendment to Section 4921 of the U. S. Statutes which deals with damages and profits, so that the sentence will read as follows: "In the absence of adequate proof of the amount that should be awarded as damages or profits, the Court, on due proceedings had, may adjudge and decree to the owner payment of a reasonable royalty or other form of general damages." He believes that no statute should directly or indirectly contemplate a condition in litigation in which "proof is not offered" and that the courts in applying the clause would be embarrased if the phrase "if proof is not offered" were in the statute.

(Concluded on page 199)

A NEW THEORY OF THE STEAM TURBINE[1]

By HAROLD MEDWAY MARTIN

(From articles published in *Engineering*)

IN THE investigation of the performance of steam turbines some notable discrepancies between theory and apparent practice were discovered, one of these being that under certain conditions the weight of steam discharged from a nozzle was actually greater than what was physically possible according to the then accepted theory. At first it was attributed to the moisture in the steam, but this explanation was discarded when it was found that to bring this theory into accord with experiment would involves the presence of anywhere between 10 and 20 per cent of moisture in the steam. Later on this anomaly was attributed to a fundamental error in the then accepted theory of the efflux of steam; namely, that the expansion of wet steam did not proceed under conditions of thermal equilibrium as was previously assumed.

The present theory is based on an assumption claimed to be proved by actual experience with steam turbines: namely, that not only is steam not in thermal equilibrium in the "saturated field" of the Mollier diagram, but it is never in thermal equilibrium until the condenser is attained. The relation between volume and pressure during the expansion of wet steam is accordingly never the same as if a state of thermal equilibrium were established.

In opening a turbine it is easy to see the difference in the appearance of the blading which has been exposed only to superheated steam and that which, on the ordinary theory, has been subjected to the action of wet steam. In the region where the steam was supersaturated a film of moisture is deposited on the blading and it is this very phenomenon that for a long time interfered with the detection of undercooling in steam turbines and steam engines. In any attempt to take the temperature of the steam by means of a thermometer a film of moisture was immediately deposited on the bulb or on the exterior of the thermometer pocket if the steam were supersaturated, and the thermometer recorded the temperature of this film and not that the surrounding vapor. Hence, for many years it has been noted that the temperature of the steam as indicated by a thermometer placed in a turbine exhaust pipe was sensibly below that corresponding to its pressure. These low readings are all the more remarkable in that experiment has shown that when a thermoscope is immersed in a current of permanent gas it tends to give too high a reading, owing to adiabatic compression of the fluid against the obstacle.

The writer mentions a possible objection against the idea that there is any large degree of undercooling in the turbine exhaust, viz., the fact that in experiments with a nozzle discharging into open air Dr. Stodola showed that once condensation commenced it proceeded with extreme rapidity. However, he calls attention to the fact that the occurrence of condensation or even its completion does not necessarily imply the simultaneous establishment of thermal equilibrium. In fact, there is evidence in favor of the view that there is a sensible lag between the two.

In the experiments of Stodola the droplets observed by him in his jets of undercooled steam were formed in a period of time of the order of one ten-thousandth of a second, while the time occupied by steam in flowing through the low-pressure end of a turbine is some hundred times as great. Were it not for the lag between condensation and thermal equilibrium, it is difficult to see how these droplets could be built up with such rapidity. Each molecule as it condenses liberates energy sufficient to raise its own temperature by some 500 or 600 deg. cent. and were this energy immediately and wholly transformed into heat, it is difficult to see how the temperature of the surface could be kept low enough to permit of the building up by further condensation of the droplets observed by Dr. Stodola.

The writer also brings forward the following interesting reasoning to prove that the instantaneous conversion into heat of the energy liberated on condensation is unlikely. He claims that the forces responsible for the attraction between the molecules of the same substances to which the phenomenon of liquefaction is due, are essentially of the same nature as the forces holding together a chemical compound, i.e., electrical. There are thus good grounds for believing that the energy liberated on the condensation of a vapor is at the outset represented by electrical disturbances and is only somewhat gradually converted into the form of heat. In support of this view he cites the paper of Wilson in the *Philosophical Transactions* for 1897, where the latter states that if the expansion of dust-free vapor was just sufficient to produce condensation the number of droplets formed was of the order of 10^8 per cu. cm., but that this number increased very rapidly if the range of expansion was increased. This affords direct proof that the additional condensation took on new nuclei and the temperature of the vapor must accordingly have been far below the equilibrium value during the whole range of expansion. The time taken for the expansion in Wilson's experiments was estimated at something over 1/50 of a second and was thus of the same order as the total time taken for steam to pass completely through a modern steam turbine, the inference being that the steam as finally discharged from such a turbine is used in a greatly undercooled and supersaturated condition.

The writer in the present paper attempts to show that if his interpretation of Wilson's results be accepted i. e., that the expansion continues with the vapor temperature far below that which would be indicated by any thermometer immersed in it), both superheat and vacuum corrections can be rationalized, while a contrary view involves wide discrepancies between theory and practice.

It is a well-known fact that in steam-turbine practice the gain made by the use of superheated instead of saturated steam is substantially more than is thermodynamically due. This was shown quite conclusively by Baumann in a paper read before the Institution of Electrical Engineers (British) in 1912. Last year an extended set of correction tables drawn up by C. H. Naylor was issued under the auspices of the British Electrical and Allied Manufacturers' Association. From these figures, combined with the heat-drop tables issued by the same association, the present author secured the following figures of relative consumptions under certain standard conditions:

TABLE 1

Superheat, deg. fahr.	0	50	100	150	200	250	300
Relative consumption	1 160	1 101	1 046	1 000	0.9592	0 9235	0 8909

From these figures and other data it would seem that the saving due to a superheat of 150 deg. fahr. is reckoned at 16 per cent instead of at 15 per cent as in Baumann's paper in 1912. This may be due to the improvement effected during recent years in average turbine efficiency, since, as the writer claims, with any given type of turbine the relative gain from using superheat should increase somewhat with the efficiency of the turbine. This is the reverse of the opinion generally held.

From this the writer proceeds to the consideration of the discrepancies between the gains and losses. To do this he takes for purposes of comparison the condition of the steam, not as supplied to the stop valve but after passing through the governor valve. In addition, the discrepancies are made larger by the fact that the ratio of blade speed to steam speed is, on the average, less the greater the amount of available heat. Furthermore, the

[1] Abstract of an important paper which appeared serially in the latter part of 1918 in *Engineering* (London). While the first installments were reported in THE JOURNAL for September, October and November 1918, it has nevertheless been deemed desirable to present in one issue a conjoint abstract of the entire investigation. Because of the lack of space one section of considerable interest abstracted in the September issue has been omitted here. This refers to the modified Callendar steam table and directions for using it.

heat which becomes available in a steam turbine differs from the adiabatic heat drop and is, in general, considerably larger. The ratio of the two, known as the reheat factor, forms the subject of an important discussion by the writer, who claims that it is substantially greater for superheated than for saturated steam when the latter is assumed to be in thermal equilibrium throughout the whole of its expansion.

Suppose a turbine to consist of an infinite number of stages. At each stage a certain portion of the total energy of the steam is converted into kinetic energy, of which a part is expended in doing useful work on the shaft, and the remainder, which is wasted in friction, is restored to the expanding steam in the form of heat; the consequence is that at each stage the pressure corresponding to a given volume of the steam is somewhat greater than it would be did the turbine work friction-free. Whether steam be used to actuate a turbine or a reciprocating engine the amount of work done down to any stage of the expansion can be represented by an ideal indicator diagram such as is shown in Fig. 1. In this the expansion line BD is that corresponding to frictionless working or to unit efficiency, while BE represents the expansion line for a turbine working with a hydraulic efficiency η. The total area of the diagram is in this case larger than before, because the energy wasted in friction, being returned to the steam as heat, makes the volume at every point of the stroke more than if unit efficiency were attained. On this larger diagram, however, only the fraction η is recovered as useful work on the shaft, whereas in the ideal case of unit efficiency the useful work done is represented by the whole of the area $ABDC$. In all cases $\eta \times ABEC$ is less than $ABDC$.

The efficiency ratio ε of the turbine is equal to the actual work done divided by that theoretically due from a perfect turbine, or

$$\varepsilon = \eta \frac{ABEC}{ABDC}$$

and the reheat factor R is defined by the relation

$$R = \frac{ABEC}{ABDC}$$

so that $\varepsilon = \eta R$, where η is known as the hydraulic efficiency of the turbine.

The actual thermodynamic head under which any turbine works is therefore not represented by the adiabatic heat drop u, but by a larger quantity U, where $U = Ru$.

From this the writer proceeds to show how to determine the value of the reheat factor corresponding to different values of the hydraulic efficiency of the turbine and comes to the expression

$$R = \frac{1}{\eta} \cdot \frac{1 - \left(\frac{1}{x}\right)^{\eta[1-(1/\gamma)]}}{1 - \left(\frac{1}{x}\right)^{[1-(1/\gamma)]}}$$

where η is the hydraulic efficiency of the turbine and x the ratio of the initial to the final pressure. From this he derives the values of the reheat factor for superheated steam throughout the whole range of its expansion for the various hydraulic efficiencies given in Table 2.

In other words, the efficiency ratio of a turbine is defined as the product of its hydraulic efficiency and the reheat factor.

In view of its use elsewhere in this discussion attention is called to the following expression for λ:

$$\lambda = \frac{1 + \frac{1}{\gamma - 1}}{\frac{1}{\gamma - 1} + k}$$

where γ is the index when the expansion is adiabatic.

Among other things the writer calls attention to the paradox following from the above expression for the reheat factor R. If the expansion be carried far enough, the efficiency ratio is independent of the hydraulic efficiency which can be shown by making $x = \infty$. Since then the efficiency ratio is equal to $R\eta$, its value is always unity if the expansion be carried to zero pressure. The following physical explanation is given: To reduce the final pressure to zero we must go down to the absolute zero of temperature. In deducing the value of R it was assumed that all the heat energy not expended in doing useful work was restored to the fluid in the form of heat. At the absolute zero of temperature the working fluid retains no heat energy and the latter has accordingly all been turned into useful work and the efficiency ratio is unity, however great the frictional losses may have been at each stage of the turbine.

The writer points out that the error in reheat factors for wet or saturated steam is considerable, because for the adiabatic expansion of such steam in thermal equilibrium the expression of the form pV^n = constant (where $n = \gamma$), is only moderately accurate. In such a case the reheat factor may be determined in

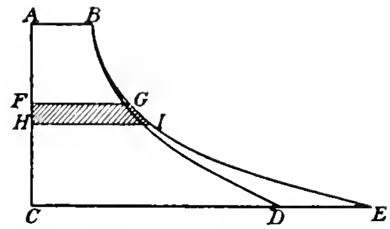

FIG. 1 IDEAL INDICATOR DIAGRAM FOR STEAM TURBINE

another way, published in *Engineering* several years ago. The writer repeats the argument presented there and gives a table

TABLE 2 REHEAT FACTOR FOR STEAM SUPERHEATED THROUGHOUT THE WHOLE RANGE OF ITS EXPANSION

Values of $x = \frac{p^0}{p^1}$	Hydraulic Efficiency η			
	0.5	0.6	0.7	0.8
1	1.0000	1.0000	1.0000	1.0000
2	1.0393	1.0312	1.0235	1 0160
4	1.0753	1.0629	1.0463	1.0310
6	1.1033	1.0809	1.0602	1 0397
8	1.1195	1.0934	1.0695	1 0454
10	1.1310	1.1024	1.0762	1.0494
15	1.1554	1.1209	1.0891	1.0585
20	1.1691	1.1313	1.0964	1.0617
25	1.1841	1 1445	1.1057	1.0692
50	1.2219	1.1718	1.1253	1.0810
100	1.2586	1.1998	1.1450	1.0932
200	1.2962	1.2279	1.1643	1.1053

showing the value of reheat factor for steam unusually dry and expanding in thermal equilibrium throughout, that is to say, with no undercooling, a condition which is, however, not realized either in a steam turbine or in a reciprocating engine. These values are given in Table 3.

The writer makes the following comparison of Tables 2 and 3. Suppose a steam turbine designed to give a hydraulic efficiency of 0.7 for the range of expansion of from 200 lb. absolute down to 1 lb. absolute. Then if the steam supply is saturated and the expansion takes place in thermal equilibrium throughout, its thermodynamic efficiency ratio will, from Table 3, be $0.7 \times 1.0559 = 0.739$ nearly. If, on the other hand, the turbine is designed to give the same hydraulic efficiency with steam supplied at 200 lb. and superheated to such an extent that the superheat is not lost when the exhaust port is reached, the efficiency ratio will be $0.7 \times 1.1643 = 0.815$ nearly. Hence, with the same hydraulic efficiency the thermodynamic efficiency ratio will be fully 10 per cent more with superheated than with saturated steam expanding in thermal equilibrium.

It will be obvious, therefore, that the adiabatic heat drop forms a somewhat fallacious foundation for estimating the saving to be effected by superheating the steam.

The writer shows next how to determine the point at which different degrees of initial superheat are lost. Assume for example that the initial pressure is 180 lb. absolute and that the

hydraulic efficiency of the turbine is 70 per cent. Suppose the superheat to be lost at, say, 80 deg. cent. The volume of the steam

TABLE 3 REHEAT FACTORS R FOR STEAM INITIALLY IN THE DRY BUT SATURATED CONDITION, AND EXPANDED FROM DIFFERENT INITIAL PRESSURES DOWN TO 1 LB. ABSOLUTE, THERMAL EQUILIBRIUM BEING MAINTAINED THROUGHOUT THE EXPANSION

Abs. Initial Pressure, lb. per sq. in.	Abs. Final Pressure, lb. per sq. in.	Hydraulic Efficiency η				
		0.5	0.6	0.7	0.8	0.9
2	1	1.0085	1.0078	1.0065	1.0046	1.0022
4	1	1.0191	1.0163	1.0129	1.0089	1.0043
6	1	1.0284	1.0217	1.0169	1.0114	1.0056
8	1	1.0316	1.0256	1.0195	1.0130	1.0062
10	1	1.0355	1.0290	1.0221	1.0148	1.0071
15	1	1.0435	1.0348	1.0264	1.0181	1.0078
20	1	1.0496	1.0394	1.0294	1.0191	1.0088
25	1	1.0537	1.0427	1.0318	1.0210	1.0104
50	1	1.0669	1.0531	1.0394	1.0261	1.0129
100	1	1.0809	1.0640	1.0475	1.0313	1.0155
200	1	1.0956	1.0755	1.0559	1.0368	1.0162

is then 54.596 cu. ft. per lb. (Callendar) and its pressure is 6.8627 lb. per sq. in.

The initial pressure being 180 lb. absolute, we have

$$x = \frac{p_1}{p_2} = \frac{180}{6.8627}$$

If ρ be the ratio of the final volume to the initial volume then, since the expansion follows the law $pV^m =$ constant (where $m = \lambda$), we have $\rho = x^1/^m$

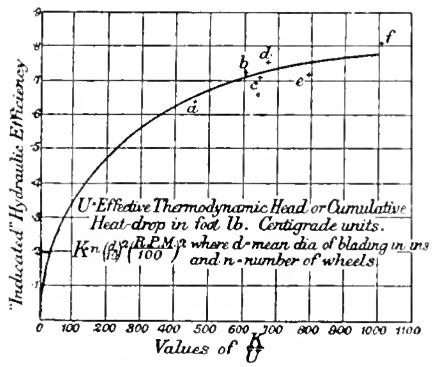

FIG. 2 "INDICATED" HYDRAULIC EFFICIENCY OF IMPULSE TURBINES IF STEAM EXPANDS IN THERMAL EQUILIBRIUM THROUGHOUT

The value of $1/m$ is given (*Engineering*, July 19, p. 53) by the relation

$$\frac{1}{\lambda} = 1 - 0.23077\,\eta = 1 - 0.23077 \times 0.7 = 0.8385$$

Whence

$$\rho = \left[\frac{180}{6.8627}\right]^{0.8385} \quad \text{and} \quad V_1 = \frac{V}{\rho} = 3.528 \text{ cu. ft. per lb.}$$

Reference to Callendar's table shows that steam at 180 lb. absolute with this specific volume has a temperature of 331.6 deg. cent., corresponding to a superheat of 142.1 deg. cent. or 255.8 deg. fahr. By determining a number of values in this way and plotting the results as curves, the temperature at which any stated initial superheat is lost can be determined. The writer gives a table showing the approximate centigrade temperatures at which superheat is lost for different hydraulic efficiencies when the initial pressure is 180 lb. absolute. With the temperatures given in such a table it is possible to calculate the total effective thermodynamic head, or, to use Professor Goudie's term, the "cumulative heat" which becomes available in a turbine when expanding steam from 180 lb. absolute to 1 lb. absolute with different hydraulic efficiencies, the steam being supposed to be in thermal equilibrium throughout. The writer gives a table of cumulative available heats when steam expands in thermal equilibrium from an initial absolute pressure of 180 lb. per sq. in. to 1 lb. absolute with different hydraulic efficiencies and different initial superheats. This table is here reproduced as Table 4. To determine from this table the theoretical steam rate for a turbine working with different superheats a correction is required because increases in the effective thermodynamic head change the ratio of blade speed to steam speed.

This correction can be effected by means of the curve plotted in Fig. 2 on the assumption that thermal equilibrium was maintained throughout the whole expansion. In this curve the "indicated" hydraulic efficiency of a number of impulse turbines is plotted against K/U, where

$$K = n\left(\frac{d}{10}\right)^2\left(\frac{\text{R.P.M.}}{100}\right)^2$$

and U denotes Ru, where u is the adiabatic heat drop. In the above expression for K the number of stages is represented by n, while d denotes the mean diameter of the blading. Since the average velocity of the steam is proportional to $\sqrt{(U/n)}$, the expression $\sqrt{(K/U)}$ is proportional to the ratio of blade speed to steam speed. According to the ordinary view the indicated hydraulic efficiency should give a parabola when plotted against $\sqrt{(K/U)}$, and consequently the curve in Fig. 2 should be an ellipse. The points lie badly on an ellipse, however, and the curve shown has been sketched in freehand. As will be shown later, a much better agreement between the curve and the experimental figures is obtained when the theory that the steam expands in thermal equilibrium is abandoned.

TABLE 4 CUMULATIVE AVAILABLE HEATS F. P. C. WHEN STEAM EXPANDS IN THERMAL EQUILIBRIUM FROM AN INITIAL ABSOLUTE PRESSURE OF 180 LB. PER SQ. IN. TO 1 LB. ABSOLUTE; WITH DIFFERENT HYDRAULIC EFFICIENCIES AND DIFFERENT INITIAL SUPERHEATS

Hydraulic Efficiency η	Initial Superheats, Deg. Fahr.

The writer proceeds to a discussion of the results in this case and compares them with the data on Baumann's correction curves. Altogether it is found that consumption with saturated steam, assuming that the expansion takes place in thermal equilibrium, should be 1.077 times as much as with steam superheated to 150 deg. fahr., but from a table given in the original article it appears that the actual consumption of superheated steam is 1.163 times as much, which would indicate that the known values of the superheat corrections are inconsistent with the hypothesis that the expansion of wet steam takes place in conditions of thermal equilibrium.

It might be said that this discrepancy is due to the higher frictional resistance which wet steam meets, but this is at variance with an observation made by Osborne Reynolds to the effect that when the motion of fluid is such that resistance is as the square of the velocity, the magnitude of this resistance is sensibly quite independent of the character of the fluid in all respects except that of density. This view has received ample experimental confirmation, for instance, in the work of Prof. C. H. Lees. This viscosity has only a small influence on the flow phenomena and it does not appear that any material difference can be due, as far as fluid friction is concerned, to water steam if superheated or wet.

While it has been known for a long time that the assumption that wet steam was in thermal equilibrium throughout the whole of its expansion is erroneous, opinions have differed as to the importance of the consequent loss from undercooling. The most

general opinion has been that once the supersaturated steam began to condense, thermal equilibrium was practically instantaneously restored and was maintained during any specimen expansion. The writer attempts to prove that this theory does not explain the observed values of the superheat corrections.

The fact that nozzles fed with wet steam discharge a greater weight than can be accounted for on the ordinary theory has been traced to supersaturation of the steam as it passes the nozzle throat, a fact which has been confirmed experimentally by Dr. Stodola.

In this connection, it is mentioned that in Stodola's tests where ordinary boiler steam was led directly to the nozzle a cloud of spray was visible close up to the nozzle discharge, but the pressure of a spray does not necessarily prove the absence of undercooling. In the first place, it is known by experiment that a nozzle will pass a greater weight of ordinary boiler steam than would be possible with undercooling absent. Further, the drops of water present cannot cool quickly even to serve as nuclei of condensation. Professor Callendar has obtained evidence of undercooling in the cylinder of an ordinary reciprocating engine where the rate of expansion is very much slower than in a turbine, a fact confirmed by other observations cited by the writer. In this connection the writer cites Lord Kelvin's theory of evaporation of drops, one of the conclusions of which is that in no case can a drop of pure water be in equilibrium with steam of the same temperature, and the fact the droplets are observed to proceed even in the mist of superheated steam is due to the fact that such drops are not drops of pure water, but have arisen from priming containing dissolved salts and thus have a lower vapor pressure than pure water.

An interesting calculation is given showing conditions in which a drop of pure water is in equilibrium with its surroundings. The final equation is

$$\log_e \frac{p}{p_s} = \frac{1}{R\,T} \cdot \frac{2\sigma}{r} \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where p denotes the pressure in equilibrium with the drop of radius r and p_s the saturation pressure due to the temperature of the drop, σ the surface tension of the film expressed in dynes per cm., T the absolute temperature in degrees centigrade and R the constant in the ordinary gas equation. From experiments (C. T. R. Wilson) on dust-free but saturated air Callendar deduces that r is equal to 5×10^{-8} cm. This quantity is of molecular dimensions, and it is natural to conclude that the nuclei involved are the double or co-aggregated molecules which are known to exist in steam, and in truly stupendous numbers, presenting in the aggregate an enormous surface. It is not suggested that these co-aggregated molecules are actually spherical in form, but merely that considered as nuclei they are equivalent to spheres of the radius stated.

In the present connection, however, the important fact is that r is constant, so that Equation [1] may be written as

$$\log_{10} \frac{p}{p_s} = \frac{3.75\,\sigma}{T}$$

and the writer gives rather complicated formulæ for σ. Table 5 gives the values of p/p_s for different temperatures.

Table 5 shows that if steam is expanded until a temperature falls, say, to 40 deg. cent., there will be no condensation of steam unless the pressure is 6.987 times that of a saturated steam at the same temperature. This fact is sometimes expressed by the statement that the density of supersaturated steam when on the verge of condensing at 40 deg. cent. is about 7.5 times as much as it ought to be, which is misleading as it is apt to convey the impression that the specific volume of supersaturated steam is inly 1/7.5 of what it would be had expansion taken place in conditions of thermal equilibrium, which is not true. Actually at 40 deg. saturated steam has a pressure of 1.0703 lb. per sq. in., and therefore no condensation will occur unless the pressure of the steam exceeds $6.787 \times 1.0703 = 7.478$ lb. per sq. in.

From the values of p/p_s in Table 5 one can find the pressure at which supersaturated steam at different temperatures condenses, and from Callendar's equations he can then get both the corresponding volume of the steam before the condensation occurs and also its total heat, likewise the entropy of the steam just before the condensation occurs, which, in its turn may be used for plotting the Wilson line of the steam chart and the cumulative heat drop or effective thermodynamic head due to an expansion without condensation down to the Wilson line and with the subsequent expansion in conditions of equilibrium.

TABLE 5

t	$\frac{p}{p_s}$	t	$\frac{p}{p_s}$	t	$\frac{p}{p_s}$
0	11.08	40	6.987	80	5 014
10	9.727	50	6.367	90	4 685
20	8.632	60	5.841	100	4.300
30	7.732	70	5.395	110	4 152

The writer proceeds to prove by a very interesting calculation that the thermal equilibrium of expanding steam cannot be immediately reëstablished when condensation takes place at the Wilson line. In fact, Wilson found that the number of droplets formed in his experiments on the expansion of supersaturated vapor increased enormously when the expansion was continued beyond the Wilson point, which indicated that the condensation was occurring not on the droplets already formed, but on new nuclei, and the temperature of the expanding vapor must accordingly have been not higher than that of the Wilson point corresponding to the pressure. There was thus a high degree of undercooling up to the very end of the expansion, but the temperature of this undercooled steam cannot be measured by means of a thermometer, as is shown elsewhere by the present writer.

This is followed by a discussion of the mechanics of condensation of vapor. The vapor condenses because of the mutual attraction between its molecules. This attraction is electrical in origin and essentially similar to that which operates in the formation of chemical compounds. Heat is a molecular motion and is subject to the general laws of transference of energy which occurs only slowly when the energy goes from the light electron to the heavy molecule. Until this transfer is effected the energy involved does not appear as heat. It has been shown above that the assumption that the steam expands in thermal equilibrium when the expansion is carried beyond the Wilson line is inconsistent with experience, which is thus in accord with Wilson's observation that the condensation which comes down during such an expansion separates on fresh nuclei. For this comparison the curve for Fig. 3 will be used. Many of the results plotted in the earlier portion of this curve were obtained in progressive trials of a steam turbine run at different speeds and with different superheats. The steam was highly superheated so that the "indicated" efficiencies could be determined without various corrections for dummy and gland leakages and for frictional losses which make the calculation of "indicated" efficiencies of a turbine so difficult in usual tests. Other points are plotted from ordinary test data corrected for internal losses. Some of the points, however, are erratic. On the whole, the curve is believed to represent fairly accurately the relative efficiency of turbines as the ratio K/U is increased.

The value of U adopted was calculated from the writer's modification of Callendar's steam chart using the equivalent reheat factors for expansions beyond the Wilson line, and he describes in considerable detail how these equivalent reheat factors were arrived at. The values of these equivalent reheat factors for various hydraulic efficiencies of the turbine are given in a table in the original article.

The term "equivalent reheat factor" can be understood from the following discussion. It is a fundamental axiom in thermal dynamics that a gas by suitable addition of heat may be caused to expand according to any law however arbitrary. It is thus possible, for example, by the use of appropriate reheat factors to make the volume and pressure of steam expanding without condensation exactly the same point for point as the volume and pressure of wet steam expanding in conditions of thermal equilibrium. The gross work done in this "equivalent" expan-

sion is the same as that done in the corresponding actual expansion of the wet steam.

Thus, when wet steam expands in conditions of thermal equilibrium the actual volume occupied by the steam depends upon the dryness fraction. Nevertheless, the relation between volume and pressure can be represented with considerable accuracy by an expression of the form $pV^n =$ constant. If at starting the steam is just dry, then according to Zeuner the expansion takes place according to the law $pV^{1.135} =$ constant, and by the methods elsewhere explained in this paper one can calculate a series of reheat factors, which, when applied to superheated or completely supersaturated steam, will give the same law of expansion.

The difference between real expansion and "equivalent" lies in the following: In the first place, the useful work done and the relation between volume and pressure for the actual expansion in thermal equilibrium can, by the use of appropriate reheat factors,

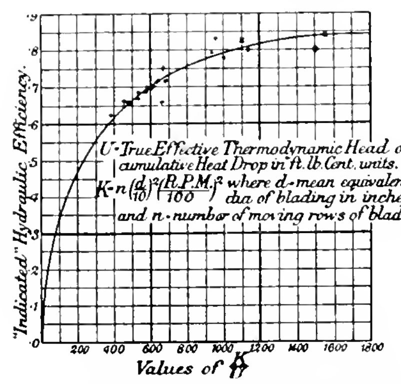

FIG. 3 "INDICATED" HYDRAULIC EFFICIENCY OF REACTION TURBINES

(Not corrected for leakage over blade tips.)

be represented by an expansion between the same limits of steam which remains completely supersaturated.

Next in the real expansion the volume occupied by the steam is diminished owing to condensation; in the equivalent expansion this real defect in the mass, actually gaseous, is replaced by an equivalent but imaginary reduction in the mass which is assumed to remain wholly in the state of vapor.

The writer then proceeds to the calculation of relative consumptions on the basis of the curve in Fig. 3 on the assumption that the steam behaves throughout as if completely superheated, which indicates the true value of the reheat factor.

From this the writer proceeds to the consideration of vacuum corrections. That the vacuum corrections are quite irrational on the ordinary theory has long been recognized, as in this theory with high-pressure turbines a reduction of the exhaust steam from 1 lb. absolute to ½ lb. absolute should reduce the consumption by some 11 per cent; whereas, experience shows that the actual improvement in the steam rate is from 5 to 6 per cent.

In this connection the writer discovered that the real discrepancy is somewhat less than these figures would imply, as no allowance has been made for the fact that the increase of vacuum involves an increase in the total effective thermodynamic head. Furthermore, the effective change in the vacuum is strictly local and materially affects only the last row of blades.

Thus, in a certain impulse turbine designed so that with normal vacuum the velocity of efflux from the last row of guide blades is slightly above the critical value, which is the speed of sound, the "use" of an important increase in the vacuum can never get back past the last row of nozzles and it is only the last wheel of the turbine that can ever get to "know" that the vacuum has been increased.

Since the whole effect of the increase of vacuum is concentrated on the last stage where both the axle and the wheel efficiencies will be reduced, the total resultant loss of efficiency of the turbine as a whole will be greater than if the increase in the thermodynamic head had been equally divided between all its stages.

The writer proceeds from this to the calculation of vacuum corrections, first considering the turbine as being operated for water and then by steam. This part of the paper, while brief, is of considerable interest as giving a clear idea of the method used by the writer, and is strongly recommended to the attention of those who can spare the time to read over the original article.

The following recapitulation of the new theory is given by the writer himself: Starting from the now accepted view that wet steam is not discharged from a nozzle in a condition of thermal equilibrium, reasons have been given for believing that in actual turbine practice, the expansion of wet steam never does occur in a condition of thermal equilibrium. Evidence of this is afforded by the condition of the steam in the exhaust branch of a turbine, where temperature measurements do not correspond with the pressure of the steam as simultaneously observed. True, the apparent defect of temperature is small, but it has been pointed out that the kinetic theory of gases requires that the readings of a thermometer immersed in undercooled steam should correspond to the pressure rather than to the temperature of this steam. That the true defect of temperature may amount to many degrees, may, it is pointed out, be inferred from Wilson's experiments on the expansion of supersaturated vapor, where, when the expansion was continued beyond the point at which moisture first separated out, the additional condensation came on new nuclei, and these new nuclei can be effective only when the defect of temperature amounts to some tens of degrees.

It was shown that on this hypothesis a rational explanation of the anomalies in superheat and vacuum corrections became possible, thus bringing theory into accord with actual experience. (*Engineering*, July 5 and 19, August 2, 9 and 23, and September 6, 1918; compare also THE JOURNAL of The American Society of Mechanical Engineers, September, October and November, pp. 784-787, 871-872 and 965-966.)

The Harvard School of Engineering has been reorganized and its courses were opened to students on January 1, and will continue during the Summer to enable the entrants to complete a full year's work by the opening of the next academic year in September. Some time ago, says the New York *Times*, Harvard University and the Massachusetts Institute of Technology agreed to combine effort in engineering instruction, making use of funds provided under the will of the late Gordon McKay. The agreement was objected to and the Massachusetts Supreme Court held that the arrangement was not in accord with the provisions of the will. The new arrangement has been approved both by the trustees of the McKay estate and by the governing boards of the university.

The instruction will be carried on entirely by a Harvard faculty, appointed by the university governing boards, and students who satisfactorily complete four years of study will receive the degree of bachelor of science. Higher degrees will be granted after additional study. Generally speaking, the work will be carried on in the classrooms and laboratories of the university, but arrangements may be made, from time to time, to utilize the facilities of other institutions, especially in the advanced technical courses. Instruction will be offered in mechanical engineering, civil engineering, sanitary engineering, electrical engineering, mining and metallurgy, and industrial chemistry.

It is provided that all grades of instruction, "from the lowest to the highest," shall be offered and shall "be kept accessible to pupils who have had no other opportunity of previous education than those which the free public schools afford." Requirements for admission to the school will be the same as those for admission to Harvard University. Admission to advanced standing and special study will be administered by the Engineering faculty.

The fees will be the same as those of the university, except that supplementary fees for additional or for laboratory courses may be charged. When funds from the McKay endowment are available, in the judgment of the President and Fellows, for the construction of new buildings for the Engineering School, such buildings will be constructed on Harvard University grounds and will bear the name of Gordon McKay.

THE PRODUCTION OF HELIUM FROM NATURAL GAS

Abstract of Address by Dr. Frederick G. Cottrell Reviewing Recent Work in the Liquefaction and Separation of Gases and the Production of Helium for Use in Balloons

On Friday evening, January 17, 1919, at the Chemists Club, the Society of Chemical Industry, the American Chemical Society and the American Electrochemical Society awarded the Perkin Medal to Dr. Frederick G. Cottrell, Chief Metallurgist of the Bureau of Mines. The medal was presented by Dr. Charles F. Chandler, senior past-president of the Society of Chemical Industry.

In accepting the medal, Dr. Cottrell spoke briefly on the subject of electrical precipitation and the patent situation leading up to the formation of the Research Corporation and its work in this and allied lines. He outlined the bill which has been introduced in both the Senate and House of Representatives at the instance of Secretary Lane of the Department of the Interior, authorizing the Federal Trade Commission to administer such patents as may be tendered to it by Government employees and others. This latter body has, during the war, been administering enemy-owned patents in much the same manner, and therefore already has the machinery and experience needed.

No matter how potentially valuable a purely scientific discovery is, it seldom benefits the public at large until it is carried through to industrial and commercial development and connects with the well-established avenues of trade. It is particularly in the case of patents on broad, fundamental projects that such an administration is of most importance.

The chief interest in the address, however, attaches to that portion which relates to the liquefaction and separation of gases and the final production, probably on a commercial scale, of the non-inflammable and buoyant gas, helium, for use in dirigible and observation balloons. It is mainly through Doctor Cottrell's work both as a scientist and in an administrative way that this has been brought about. The development came through investigations by him and others of the possibility of producing industrial oxygen at low cost by the liquefaction and distillation of air and in the application of similar principles to the production of helium from natural gas. Three development plants for this purpose are now in operation in Texas.

In the course of his remarks Doctor Cottrell referred to the recent address in New York by General Squier, Chief Signal Officer of the U. S. Army, in which the latter said that the production of helium had been so cheapened that it could now be produced at 10 cents a cu. ft. instead of the prohibitive price of \$1700 a cu. ft., which was the cost only two years ago; and in commenting, Dr. Cottrell said that if present expectations are fulfilled this cost may be still further reduced. He also emphasized the possibilities of the commercial production of oxygen for metallurgical work by the development of air-separation processes.

In this work a considerable number of well-known scientists and engineers have been engaged, including, among others, the following members of this Society: Fred E. Norton and E. A. W. Jefferies, of Worcester, Mass.; O. P. Hood, of the Bureau of Mines; Dr. Edgar Buckingham, of the Bureau of Standards, and George A. Orrok, of New York.

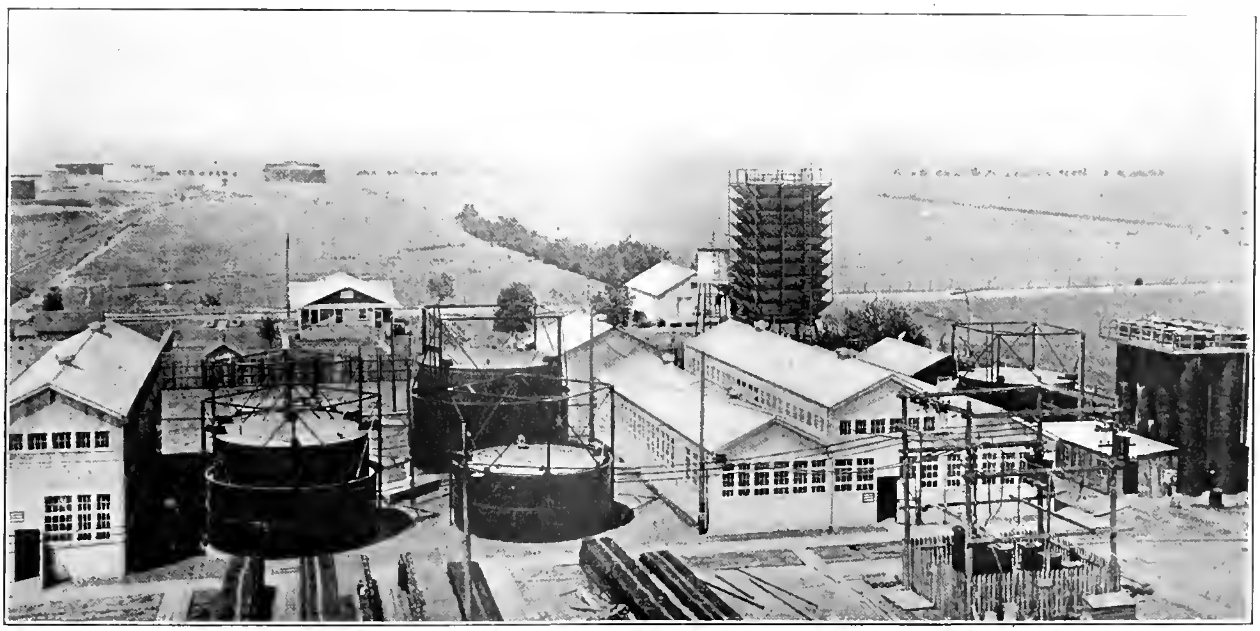

Fig. 1 U. S. Bureau of Mines Experimental Plant No. 1, at North Fort Worth, Texas

The following summarizes Doctor Cottrell's remarks:

Air Separation and Liquefaction of Oxygen

In 1904, in operating a liquid-air plant of the Hampson type at the University of California, I became greatly impressed with the ultimate possibility of producing very cheap industrial oxygen, but was equally impressed with the very crude thermodynamics which all the systems then common represented from an engineering standpoint. On assuming charge of the Metallurgical Division of the Bureau of Mines in 1916, I felt that the quest for cheap oxygen had become more than ever a large and legitimate part of my regular work; but, realizing my own limitations and the Bureau's inadequacy of material facilities, I strove to suggest, stimulate and collect inventions and developments rather than attempt to originate anything in this highly technical field.

Oxygen as sold today in steel cylinders is so expensive that it usually fails to suggest even faintly the ultimate possibilities for low-cost production, whereas on the very large scale, where unit cost of plant, overhead, sales expenses and the like are greatly reduced and compression into cylinders, transportation of the cylinders, etc., are completely eliminated, we come down to the power consumption for the actual separation as the largest and dominant factor of ultimate cost.

The final measure of theoretical efficiency is, of course, the degree to which reversibility in the thermodynamic sense has been

approached. Air is only a mixture and not a chemical compound of oxygen and nitrogen, and, therefore, no energy has to be supplied in its separation to overcome chemical affinity, but we do have to overcome what we may call the force of diffusion of the two gases in effecting their separation. In other words, we have to deal purely with that elusive second law of thermodynamics and not with the first. Thus, figured mechanically, the work necessary to separate five volumes of air at atmospheric pressure into one volume of oxygen and four volumes of nitrogen, each at atmospheric pressure, is equal to that necessary to compress the oxygen from the five volumes at 1/5 atmosphere to one volume at one atmosphere plus that to compress five volumes of nitrogen at 4/5 atmosphere into four volumes at one atmosphere, all isothermally.

In more practical engineering terms, the mechanical work necessary to separate a given amount of air into its components, oxygen and nitrogen, all at atmospheric pressure, is equivalent to that

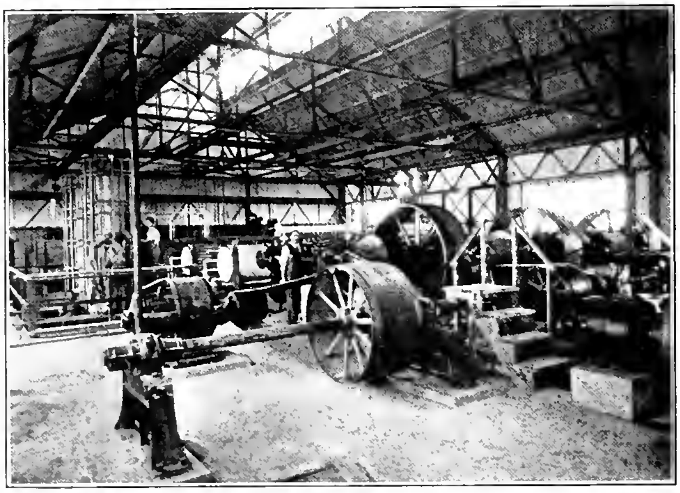

FIG. 2 INTERIOR, U. S. BUREAU OF MINES, PLANT NO. 3, J-N SYSTEM, PETROLIA

necessary to raise the same amount of air isothermally to a pressure of 9.8 lb. per sq. in. above atmospheric pressure. This figures out about 60 hp-hr. per ton of oxygen separated, or with adiabatic compression about 66 hp-hr. This is, of course, the theoretical limit for a perfect reversible cycle, which cannot be attained in practice, but we may hope to approach it to much the same degree that we have the corresponding limit in the steam engine and the air compressor, say 50 per cent as at least a legitimate goal for early endeavor. It seems doubtful whether any large-scale air-separating plants at present in service are greatly exceeding 10 per cent.

It was in March, 1916, that Director Manning of the Bureau of Mines handed me a memorandum of a conversation he had chanced to have in New York with some business men concerning a new process for air separation. The information it contained was more amusing than instructive, and I filed it with similar "clues to great inventions," and later investigated it. The trail led me back, with some little winding, to Mr. Fred E. Norton, Mem.Am.Soc.M.E., of Worcester, Mass., a graduate of '91 of the Massachusetts Institute of Technology. He had, in 1913, in connection with Mr. E. A. W. Jefferies, Mem.Am.Soc.M.E., undertaken the engineering development of a process of air separation patented by the latter and which he had made arrangements with the General Chemical Company to try out at one of their plants. Considerable work had been done when the General Chemical Company dropped the matter and Messrs. Jefferies and Norton pooled their patents as the Jefferies-Norton process and continued experimental development in a smaller way.

SUGGESTION OF THE USE OF HELIUM FOR BALLOONS

A year earlier, but quite unknown to me, Dr. R. B. Moore, of the Bureau of Mines, who had worked with Sir William Ramsay, received under date of February 28, 1915, a letter from Sir William as follows: "I have been investigating blowers, i. e., coal-damp rushes of gas for helium for our Government. There does not appear to be any in our English blowers, but I am getting samples from Canada and the States. The idea is to use helium for airships."

The importance of this proposed use of helium for balloons, and particularly for airships of the Zeppelin type, lies in the absolute inertness and non-inflammability of helium and the fact that it is of all known substances the next lightest to hydrogen, having about 92 per cent of its buoyant effect. It also shows only about one-half the rate of diffusion and consequent wastage through the balloon fabric. As the fire hazard not only from incendiary bullets in war, but also from atmospheric electricity and the power plant in both peace and war, has constituted the greatest drawback to the development of lighter-than-air craft, it is difficult to overestimate what an available supply of this gas may eventually mean in the art.

In a recent letter Dr. Moore says:

> Two or three weeks after war was declared, I attended a meeting of the American Chemical Society in Kansas City. At the general session Mr. Seibel, who had been working with Dr. Cady gave a paper on krypton and xenon in some of the natural gases of Kansas. At the end of his paper he expressed regret that at such a time, when every one was thinking of war problems his paper was of a purely scientific nature and had no practical bearing on the war. I immediately got up and said that I did not agree with Mr. Seibel; as the presence of helium in these wells could, and should, have a very practical bearing on the war; as this gas could be extracted in quantity from the natural gas and used for balloons and Zeppelins. I pointed out some of the natural advantages of helium over hydrogen, and quoted Sir William Ramsay's letter. The general attitude of those present was one of skepticism. The same day I talked to Dr. Parsons who was present at the meeting and who was returning to Washington almost immediately. I told him what had happened and told him that I believed the matter should be taken up by the Bureau at once, and presented to the War Department. He promised that he would do this as soon as he got to Washington and I know that he did take the matter up with other Bureau officials.

News of Ramsay's suggestions also reached this country through other channels and were later called to our attention. Col. G. A. Burrell, who headed the Research Department of the Gas Warfare Service at the American University, tells me that Cady's experiments had also suggested similar possibilities to him.

On June 1, 1917, Doctors Moore and Burrell, both of the Bureau of Mines, called on Colonel Chandler, in charge of the Balloon Service for the Army, and explained the whole subject to him. He was intensely interested, at once realized its potentialities and asked that a report be made to him, giving all available details. He also took up the matter with Mr. G. O. Carter, in charge of hydrogen plants for the Navy, who had had several years' practical experience in the Linde Air Products Company with the liquefaction and separation of gases by their process. Mr. Carter also immediately appreciated the importance of the subject and urged this upon the attention of his superior officers.

REPORTS BY BRITISH ADMIRALTY AND U. S. BUREAU OF MINES

About this time I was called actively into the conference and was much impressed by the weight which the British Admiralty apparently laid upon the cost of separation of gas as a determining factor in its practical availability. They had figured this out on the basis of the well-known commercial processes of gas separation by liquefaction and separation and were unable to see how they could hope for production at less than $60 to $80 per 1000 cu. ft., which they felt to be practically prohibitive.

It was at this stage that I suggested turning to Mr. Norton at least for a plan and estimate of what he thought might be accomplished along the new lines he had been following. On Monday, June 4, with Mr. T. B. Ford, then in charge of the Low-Temperature Laboratory at the Bureau of Standards, and Mr. O. P. Hood, Mem.Am.Soc.M.E., Chief Engineer of the Bureau of Mines, we spent the whole day in thrashing out the whole subject with Mr. Norton. As a result Mr. Norton was asked to act as a consulting engineer of the Bureau of Mines and prepare plans and estimates for an experimental plant.

In due course a formal report was made by the Bureau of Mines to the Army, and although this was as yet fragmentary and based on very inadequate data concerning the practical conditions to be met, the Aircraft Board recommended on July 31, 1917, an appropriation of $100,000, half each from the Army and Navy, which became available for the use of the Bureau of Mines on August 4.

A detailed survey of field conditions, to determine the best available supply of natural gas for the purpose, was at once begun by Dr. H. B. Cady, as was also the preparation by Dr. Norton of working drawings for the experimental separation plant.

Mr. Burrell next communicated with the two well-established operating companies controlling, respectively, the Linde and Claude systems of gas liquefaction and distillation, to determine whether it would be possible to work out a plan for pooling of information and facilities for this specific war purpose. Due to the questions of trade secrets and business relations, this did not, however, prove possible, though both companies expressed themselves as entirely willing to undertake independent efforts and the erection of plants of their own respective designs at cost, or even less, and have ever since most cordially furnished every facility in their power to make the work as a whole a success.

Construction of Linde, Claude and Norton Plants

Further appropriations of $500,000 and $100,000 were made by the Aircraft Board and contracts were entered into with the Linde Air Products Company and the Air Reduction Company for the Linde and Claude plants respectively, each for an estimated daily production of about 7000 cu. ft. of helium.

Some doubt remained in the minds of the Government officials regarding the Norton process and the Secretary of the Navy, feeling the need of further outside advice in the matter, requested the National Research Council to investigate the project with special regard to its theoretical soundness and also its apparent chances for practical success.

The Council appointed for this purpose a committee of five, consisting of Prof. H. N. Davis of Harvard, Dr. Edgar Buckingham, Mem.Am.Soc.M.E., and Chas. W. Waidner of the Bureau of Standards, Dr. W. F. Landis of the Air Nitrates Corporation, and Mr. S. L. G. Knox, consulting mechanical engineer, and recently Scientific Attaché to the American Embassy at Rome. This committee, after very careful comparative study of the three processes, concurred in the Aircraft Board's recommendation of the additional $100,000, which was then immediately made available by the Army and Navy.

These plants were to be located at North Fort Worth, Texas, and operate on a natural gas containing about 0.9 per cent helium by volume, of which the Lone Star Gas Company was bringing some 20,000,000 cu. ft. daily through its pipe lines from the wells at Petrolia, about 100 miles northeast of Fort Worth to that city for domestic and industrial consumption.

It was decided to locate the Norton plant at Petrolia in direct proximity to the wells, a procedure which had not been deemed practicable for the other two plants on account of their larger demands for power and water supply.

In order properly to coördinate all the different agencies concerned, the conduct of the helium work as a whole was about this time placed in the hands of a committee consisting of one representative from each of the departments chiefly concerned. Mr. G. O. Carter, Chairman, represented the Navy, Dr. H. N. Davis the Army, and Mr. Geo. A. Orrok, Mem.Am.Soc.M.E., the Interior.

The Linde plant, costing in round figures $300,000, was the first to be contracted for and have its construction started. It produced the first helium on March 1, 1918, and by September 6 had increased its yield to 7750 cu. ft. per day of 67 per cent purity, which was later repurified to about 92 per cent.

The Claude plant, costing about half as much as the Linde, commenced production some weeks later than the latter and has also gradually increased its production and purity of products.

At the time of signing the armistice the first shipment of 147,000 cu. ft. of 93 per cent helium was on the dock about to be loaded aboard ship for Europe.

Fig. 1 shows the Linde plant at North Fort Worth and Fig. 2 the Bureau of Mines' experimental station containing the Jefferies-Norton plant at Petrolia.

The Army and Navy have now jointly entered upon a larger production program under the immediate direction of the Navy and have allotted some $5,000,000 for the construction of a new pipe line and additional units of the Linde plant at Fort Worth.

A large part of the credit for the promptness with which this actual production was effected is due to Mr. Carter who was tireless in his efforts in pushing matters of priority, transportation, construction and production.

The Norton, or Bureau of Mines, plant at Petrolia was completed as far as initial construction is concerned the middle of October, and since that time has been undergoing tests and adjustments of its various parts. The multi-tubular heat interchangers and large expansion engines, which were among the new departures in this plant, have worked out very well and now seem to be performing their allotted tasks to complete satisfaction. A good deal of difficulty was at first encountered by occasional floods of oil and salt water coming over from the Lone Star Gas Company's gasoline-extraction plant, which clogged up the interchangers, making it necessary to shut down and go through the laborious process of thawing out the whole system and starting refrigeration afresh. This has now been eliminated by the installation of adequate settling chambers and traps, and tests and adjustments are proceeding upon the stills which form the last part of the equipment to be so tested. Temperatures as low as — 168 deg. cent. have since been attained in the Norton plant.

Cycles of Operation

At the conclusion of his address Dr. Cottrell showed by means of lantern slides the details of the various plants. We reproduce four diagrams from among these pictures showing the Ideal cycle, the Linde cycle, the Claude cycle, and the Norton cycle, and Dr. Cottrell has contributed a written description of the several processes for publication in MECHANICAL ENGINEERING, which here follows: G. A. O.

DESCRIPTION OF CYCLES OF OPERATION

In studying the different systems of gas liquefaction and separation it is very essential at the outset to distinguish clearly between the production of liquid as an ultimate product and the utilization of liquefaction and reëvaporation as a mere step in a separation where the ultimate products desired are still gases and at essentially the temperature of the original mixture fed to the apparatus.

In the former case a very considerable expenditure of work is represented in what we may colloquially term the refrigerative properties of the liquid delivered.

But in the second case, where the liquid is not drawn off from the apparatus and its amount therein remains constant, the part continually evaporating serves to condense nearly an equivalent amount of the incoming gases. Also the cold gases furnished by this evaporation take up heat from and cool the fresh incoming gas while they themselves are returning to room temperature.

Ideal System

Thus, we may illustrate diagrammatically, as in Fig. 3,[1] the continuous process of liquefaction and reëvaporation of a single gas. Ideal conditions would consist in perfect heat interchange horizontally between the two legs of the U-tube A and C and perfect heat insulation lengthwise along each of these and from their surroundings.

If these conditions were fulfilled and the whole system once

[1] The four cuts here shown are from a report made in the early part of this work by Mr. Norton to Mr. Burrell, outlining the problem in hand and the relation of the three processes to one another as they appeared to him.

brought to a steady state by, let us say, refrigeration of the bottom of the U-tube by some extraneous source of initial cooling, while gas was slowly passed through it, we may imagine a certain amount of liquid condensed at the bottom of the U-tube and a uniform gradient of temperature established along its two legs. Now, if the initial extraneous source of refrigeration were re-

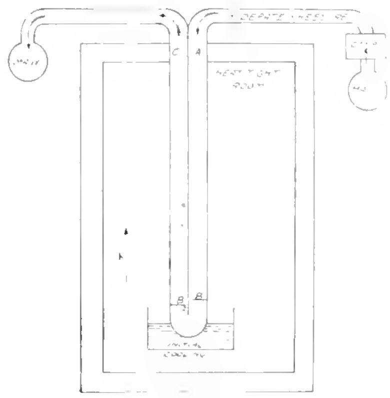

FIG. 3 IDEAL EQUAL-PRESSURE SYSTEM

moved, but gas still passed slowly into the system, the gas would progressively cool in A; liquefy at B; reëvaporate at B_2 and warm back to atmospheric temperature in passing up C. Under these ideal conditions, with a single gas, the slightest imaginable difference in pressure between A and C should serve to perpetuate the process.

Whatever heat leakage there is, however, either through the walls of the insulating chamber or down the legs of the U-tube, represents a loss not of energy itself but of its availability for the purposes in hand; i. e., of thermodynamic potential, or an

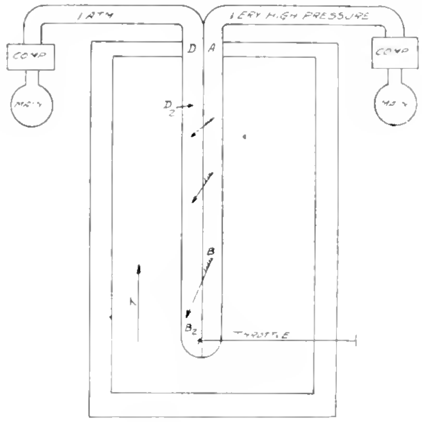

FIG. 4 LINDE SYSTEM

increase of entropy, if one prefers that terminology, the practical result being the necessity of expending mechanical work to compensate for these heat leaks. If, in addition to this, we are dealing with a mixture instead of a single pure gas, the constituents will in general liquefy and reëvaporate with varying ease, tending to set up temperature differences between adjacent parts of the two legs of the U and thus require a further expenditure of work to operate the cycle.

Looked at from the point of view of gas separation, the first of these effects represents pure loss, but the second is due, at least in part, to overcoming what we have above termed the force of diffusion in separating the gases and should thus be conuted as useful work.

The problem is, therefore, to provide just enough refrigeration *at the proper temperature and places* to cover these two demands after they themselves are reduced to as low a value as possible in the design of the apparatus and by use of the best heat insulation attainable.

The three systems for gas separation now before us differ perhaps most strikingly of all in the way in which they produce this refrigeration.

LINDE SYSTEM

In the Linde system, Fig. 4, the gas mixture to be separated is pumped at very high pressure (say 1500 to 3000 lb. per sq. in.) into leg A and simply allowed to expand through a regulating throttle to a lower pressure at B_2 and return through D, the refrigeration being usually credited to the "Joule-Thomson effect." A discussion of this latter here would carry us too far into theoretical physics, but it may help the uninitiated in such matters to intelligently picture the general effect of this process to say that the specific heat of a highly compressed gas is usually

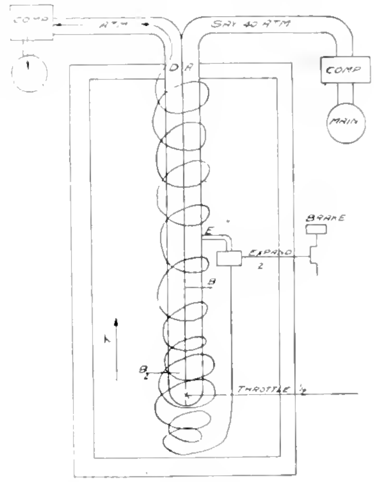

FIG. 5 CLAUDE SYSTEM

less than that of the same gas at lower pressure, so that a given weight of gas passing down leg A under high pressure in falling from one temperature to another will give up fewer calories of heat than the same weight of gas coming up the leg D will absorb between the same two temperatures. Thus it is evident that on the whole more heat will be carried out of the system by the issuing gas than is brought in by the incoming, with resulting refrigeration.

The fact that these differences of specific heat only become important at considerable pressures and the pressure created for this purpose is practically wasted at the throttle, as far as useful mechanical effect is concerned, makes this process decidedly inefficient from a thermodynamic standpoint; i. e., from the question of power consumption. Its chief merit lies in its extreme simplicity and freedom from moving parts. It is the type of system first developed both in the laboratory and commercially. As cooling proceeds, liquid finally forms at B_2. For the purpose of separating the constituents of the mixture the leg D is developed into a "column still" on the same principle as those used for rectification of ordinary liquids, but, to avoid confusion, not shown in the present cuts.

CLAUDE SYSTEM

In the Claude System, schematically represented in Fig. 5, another principle is introduced. It was early pointed out by Lord Kelvin and others that, if some sort of expansion engine could be substituted for the free-expansion throttle in systems of the Linde type, and the work of these engines expended outside the heat-tight room, greater refrigerative effect would be produced even if all the mechanical work so produced were allowed to go to waste, for in its mere production it would have already extracted an equivalent amount of heat from this room. As, for the purposes in hand, these engines must work at very low temperatures, grave mechanical difficulties were seen in the problems of lubrication, brittleness of valves, stoppage by frozen impurities from the gas and the like. George Claude of Paris was the first to solve these difficulties, at least in a commercial way, and his book,[1]

MACHINE SHOP SESSION

Papers and Discussion on Standardization Subjects at the Annual Meeting, Arranged by Sub-Committee on Machine Shop Practice

THE Sub-Committee on Machine Shop Practice carried through a timely undertaking at the Annual Meeting in its session for the discussion of papers on standardization subjects contributed from authoritative sources, both in England and America. These papers were published in the November and December numbers of THE JOURNAL, and had the following titles, which are descriptive of their contents:

THE BRITISH ENGINEERING STANDARDS ASSOCIATION, C. le Maistre, Secretary of the Association.

WORK OF THE BRITISH ENGINEERING STANDARDS ASSOCIATION ON SCREW THREADS AND LIMIT GAGES, Sir Richard Glazebrook, C. B., F. R. S., Director of the National Physical Laboratory.

PRESENT PRACTICE IN THREAD-GAGE MAKING, Frank O. Wells, Member of Congressional Screw-Thread Commission.

MEASUREMENT OF THREAD GAGES, H. L. Van Keuren, in charge of gage testing, Bureau of Standards, and Secretary of Screw-Thread Commission.

STANDARDS FOR LARGE TAPER SHANKS AND SOCKETS, Luther D. Burlingame, Brown & Sharpe Mfg. Co.

R. E. Flanders, Chairman of the Sub-Committee on Machine Shop Practice, presided, and in opening the meeting said that while the papers had been prepared under conditions incident to the war, the subject of standardization has its peace-time value as well, and particularly in relation to the international aspects of the question. It would be a misfortune for the engineers of France and the engineers of other great industrial countries each to standardize their own practice, their own work and their own product without reference to the practice, work and product of the other great engineering and productive countries. In order, therefore, that we may be kept in a current of standardization with our allies, it has been thought wise to have presented reports from authoritative sources as to the fine standardization work which has been done, particularly in Great Britain.

BRITISH ENGINEERING STANDARDS ASSOCIATION

The first paper, on The British Engineering Standards Association, was presented by Gen. L. R. Kenyon of the British War Mission, who explained the relationship of the association with the British Government. "In my country," he said, "we generally find it best—I have been a government official myself—to get along without the government in most cases. The government is apt to be rather 'red tapy' and slow in its methods, hence this matter of standardization was taken up by a number of engineers connected with the engineering societies in London. They asked the various government departments to coöperate by putting members of these departments on the committees of the association and allowing people to be sent to give evidence before the committees.

"This work began in 1901 under a slightly different name from that which it now has, and to show how modestly it started, it will be seen from Mr. le Maistre's paper that there were only seven men on the original committee, whereas now the association includes 100 different committees and sub-committees, with something like 900 members. They all work under one central authority, composed of boards nominated by the leading technical institutes in Great Britain, such as the Institution of Civil Engineers, Institution of Mechanical Engineers, Institution of Electrical Engineers, the Iron and Steel Institute, the Institute of Naval Architects, etc."

Sir Richard Glazebrook's paper was next presented by H. Bingham Powell, Director of the Joint Gage Laboratories of the British War Mission and of the U. S. Bureau of Aircraft Production. Mr. Powell said in part:

"Although Sir Richard Glazebrook is principally known as the Director of the National Physical Laboratory, he has done much other important work during the war. He has the official position of Consulting Scientist to the British Government, where his wide knowledge of physical science has been of great value.

"Quite early in his career he was demonstrator of physics at the Cavendish Laboratory of Cambridge University. He has written many books and papers for the Royal Society and other scientific and technical societies and journals; and has also been a President of the Institution of Electrical Engineers. He has taken an active part in standardization, especially in relation to screws, and it is of the latter I would now like to speak.

"Sir Richard presided over the Anglo-American Conference on screw threads held in London early in the year. That conference was not able to arrive at final decisions, but useful work was done. In concluding the proceedings, it was agreed that the principal reports of the members of Sub-Committee on Screw Threads of the British Engineering Standards Association should be published in a summarized form in the United States—to present the views held in England on the advantages and objections to the angles, forms, pitches, etc., of the various thread systems in use.

"I was charged by the committee to do this work and have presented the summary, together with some writings of my own on the subject, to the Standards Committee of your Society, and to the National Committee on Screw Threads.

"The ideas held in England may be briefly presented as follows: The British Standard Fine series of threads is becoming very popular for ordinary engineering work. It has long been felt that the British Standard Whitworth Series and the United Standard Series—which are identical except for one size, $\frac{1}{2}$-in. diameter—are too coarse for ordinary work; that is, contain too few threads per inch of length. On the other hand, they claim that the American Society of Automobile Engineers' series is unnecessarily fine for ordinary purposes.

"The British Standard Fine series is almost mathematically a mean in coarseness to these mentioned, and so would seem to meet all common requirements.

"It is most desirable, in many ways, that an international screw system should be adopted; and the feeling in England is that if we can agree in the matter of pitches, the form and angle of the thread can be allowed to take care of themselves; at least for the time being.

"Although the form of the United States Standard thread looks so different on paper from the Whitworth form, in practice there is not much difference. The square top and bottom of the United States Standard are hardly ever found in ordinary commercial screws made by taps and dies, or rolled. The crests of the thread in a tap, or in a cutting or rolling die, very soon become rounded in use by the corners overheating and falling away—thus early arriving at a radius which measurements show approaches the figure of 0.137 multiplied by the lead.

"This is the proportion laid down for the Whitworth rounding. The latter would thus appear to be about the correct rounding with which a tool maintains a stable point.

"Also, the roots of taps and cutting or rolling dies do not give a square form to the product—even if they are made of that shape—but a rounded form, similar in radius to the Whitworth. This is probably due to the fact that in such work the operation of forming the thread on the product is really partly that of extrusion; that being so, the square or sharp V root is not suitable and the metal refuses to flow completely down in it, remaining rounded, as stated.

"Thus we do not differ much over form; but should it be really considered necessary to give a complete solution to the problem, we could fix a 'zone of tolerance of form' at the root and crest of the thread, to include both the nominal square shape and also the rounded.

"About the angle of the thread: The variation of this actually found in the product is so great that the nominal difference of 5 deg. between the U. S. Standard and Whitworth threads is not

of great consequence. We have conducted many experiments in our laboratory—and in England also they have extensively investigated the point—and we find that with the same pitch the average Whitworth bolt will assemble in the U. S. nut, or vice versa; either freely or using a light wrench."

Discussion on Standardization

Henry Harrison Suplee called attention to the importance and value of standardization if rightly carried out. The great desideratum is that standardization shall be applied to details, such as rail sections, bolts, nuts, etc., rather than to the standardization of the whole design. A good example is that of aircraft work, to which General Kenyon referred. Undoubtedly this work has been unnecessarily retarded by many, many small changes, whereas standardization in details would have greatly accelerated production. At the same time standardization in the whole design would have retarded the work and perpetuated obsolete types. In the event of making improvements, the designer would be able to assemble any new design without departing radically from standardized parts. It is desirable that we should consider standardization as it relates to details, which can become almost antiquated without serious detriment, and keep it carefully away from general design where it may retard progress.

Chester B. Lord discussed the difficulties experienced in attempting to use thread gages in manufacturing operations, and said that "nothing has been more costly during the war, or done more to retard work, than the thread gage; not because it is harmful in itself, but because we have so far outstripped in our art of making threads the art and method of making gages." He emphasized the effect of drawing a thread when a bolt is stressed, by which mating threads of different shapes conform to one another, in consequence of which it is the lead rather than the shape of thread which counts. Consideration of the material on which a thread is to be cut is of the greatest importance in making a thread gage—whether open-hearth or bessemer steel, brass, copper or cast iron. He had manufactured with Whitworth, U. S. Standard and V threads as a basis on different work, and hoped later to be able to contribute a discussion in writing covering his views.

James Hartness emphasized the importance of the accomplishments of the two great institutions, the National Physical Laboratories of the British Government and the Bureau of Standards in this country. The latter came into the work a little later, and under less pressure, but has been making remarkable headway, and both are built around men who have the highest ideals and are endowed with the clearest perception with regard to gaging standards.

Commenting on the remarks by Mr. Lord, he said that while the purpose of gaging is to determine the character of the fit, we must measure the screw thread before it enters under the stress of its work. The gage, therefore, does not indicate what the fit will be when the screw is under stress. He hoped later to present a communication to the Society on this phase of the subject, and for the present would merely say that the work of the projection lantern as it has been first worked out under the auspices of the National Physical Laboratory, and as it is being carried forward by the Bureau of Standards, promises to bring us one step forward in the art of making screw threads.[1]

E. J. Bryant[2] said that in this thread-and-gage proposition we should remember that the purpose of a screw thread is to bind parts together. As a manufacturer of threads, gages and other parts, the thing which seemed to him to be vital to consider was what the standard of variation should be from the pitch or effective diameter of the thread. Knowing that, we would be able to make gages that would check the parts, and to make parts to these gages which would interchange with the parts made by other manufacturers.

[1] Mr. Hartness' communication appears in this number of Mechanical Engineering, pp. 127-135.

[2] Supt. Small Tools Division, Taft-Pierce Mfg. Co., Woonsocket, R. I.

The Engineering Standards Committee

Comfort A. Adams spoke of standardization as a basic matter of the greatest importance, and of the work of standardization contemplated by the recently organized American Engineering Standards Committee. [See Mechanical Engineering, January 1919, p. 70.—Editor.]

If a thread has been standardized, all that is necessary to designate it is to say that it is a standard thread of a certain diameter. That describes the whole thread. It is known the nation over. If it is an international standard, it is known the world over.

Another illustration is the rating of electrical machinery. It took some time to develop a satisfactory system of rating by which it would be known exactly what was meant where one said that a motor of a certain voltage, for example, had a certain horsepower. It might take many pages to describe the motor, to tell how to test it and how to check the rating; but today, in view of standardized ratings, the designating term for a motor signifies a certain definite thing which is understood not only throughout this country, but in England as well.

Standardization produces a language of marked abbreviation and results in a saving of time and misunderstandings which has been of tremendous benefit and of immeasurable importance to the engineering world.

The extent of the saving through the adoption of standards in the electrical industry is incalculable. As the world of industry develops and our relations with other nations become more and more intimate, it becomes more and more necessary that we talk the same language. Every difference in language of any kind or description creates a barrier between nations and helps to produce the misunderstandings which cause war.

With regard to the American Engineering Standards Committee, while its organization is different from that of the British Engineering Standards Association, it is hoped that it will be effective and will result in a large saving of time and bring about a better understanding in our international relations.

The operation of the Committee can best be explained by stating the order of procedure in the development of standards under the guidance of that Committee.

A standard is proposed and accepted as desirable by the Committee. It is then referred to the sponsor society, which appoints a Sectional Committee representative of that society and of other interested organizations, roughly in the proportion of their interest. The personnel of that committee is referred for approval to the American Engineering Standards Committee, and if the constitution and personnel of the Sectional Committee satisfy the main committee and its regulations in that respect, the personnel is approved, and the committee goes to work and evolves the standard, which becomes at first the standard of the sponsor society, and is published by it. Then if approved by the main committee of the American Engineering Standards Committee, the sponsor society is granted the right to have printed on the pamphlet of issue the statement—"Approved by the American Engineering Standards Committee." Thereby that standard becomes an American standard. We have been in the closest touch with the British committee, and with Mr. le Maistre, and in the future we hope that the international conferences will include the American Engineering Standards Committee.

Pioneer Mechanic Introduced

Frank O. Hoagland, representing the Pratt and Whitney Company, whose pioneer work in gages and standards is known and recognized the world over, very appropriately and courteously referred to one of the company's old employees, saying: "Many times it is of interest to see what has been done before. One of the principal difficulties is that the men who have accomplished the most do not always care to tell about it, either orally or in writing. There is a gentleman in this hall by the name of G. S. Fallow, chief gage inspector for our company, who has been with the company for more than forty years. He was there in the days when Mr. Bond and Professor Rogers tried to establish a new art.

"These gentlemen did a lot of experimental work in this coun-

try first, and then they took their measuring bar to England and had it compared with the master bar over there. There gages were being produced then because the railroads were beginning to call for nuts and cap screws that would interchange. In those days Mr. Fallow was working at the bench and lathe, and produced thread gages which stand comparison today with the latest instruments. Some of the gages were ground in 1883. It is remarkable how close they are, considering the means at hand at that time."

Considerations in the Standardization of Screw Threads

Wm. T. Magruder (written). If another set of standard sizes of screw threads is to be added to the variety now in use in engineering construction, it is to be hoped that it will be done very advisedly and with full consideration of the materials that will be employed and the uses that will be made of the threaded members. It can probably be shown that there are more miles of bolt threads cut per annum from ordinary steel bolt stock than from any other one material or for any other one use. While special threads may be desirable for automobile tool-steel threaded members and for the bronze screws of astronomical and physical instruments, the thread upon which civilization rests and progress depends is the screw thread used in bolts and screws in general engineering machinery. It is therefore of the greatest importance that standards of materials, shapes, sizes, limits, and the like should be decided on with great care and that no radical changes be made in present practice except after very serious consideration of the millions of dollars of expense and endless confusion involved in any such change. Experience gained in changing from one standardized thread to another, and later to another in engineering manufacturing work, leads me to speak positively on the subject.

Any committee having this matter in charge should decide on what may be considered to be standard engineering materials, and should then experiment upon the relative strengths and fatigues of the threads made of these materials in machines simulating actual use. By strength is not meant solely the tensile strength of the threaded member, but rather the strengths in tension, torsion and shear. One of the experiments which we have our engineering students perform at Ohio State University is to test ordinary commercial steel machine bolts by screwing the nut up with a wrench and to see that they usually fail by stripping the threads. This would indicate that the pitch was too fine or the fit too loose.

Seventeen years ago we found it impossible to get bolts and screws cut with U. S. Standard threads from any of the manufacturers located west of the Allegheny Mountains, and had to send to Worcester, Mass., to get the desired supply of standard bolts, cap screws and studs. While such is no longer the case, it would be interesting to learn how common the old, sharp-V, American thread still is and what proportion of screw-threaded members made in the Middle West are now made to a more or less approximate sharp V thread rather than to the U. S. Standard thread.

For the last four years screw-threaded members as used on munitions have been forced to the forefront of our attention. Now that we are again to allow the manufactures of peace to lead the way, more thought should be given to the commercial needs of this branch of engineering practice. The accuracy demanded and obtained in Government work does not always obtain in commercial work.

While full credit should be given to Sir Joseph Whitworth as being the first one to bring order out of screw-thread chaos and to successfully standardize British screw threads, it should be borne in mind that the Whitworth screw thread is very difficult to duplicate, an expensive thread to make as far as accurate taps and dies are concerned, and still more difficult and expensive to cut with accuracy in the lathe. It therefore seems the part of wisdom, now that the International, French and United States screw threads are all of the 60-deg. Sellers type of thread, to retain it as a standard shape—at least until something better can be devised.

E. H. Ehrman (written). Obviously the two main points of difference between the British and American screw threads for constructional bolts rest in (1) the pitches of the finer series and (2) the contour of the crests and roots.

With reference to the first point, the difference is in all probability the result of looking at the matter from different viewpoints. The British feel that one series of pitches serves satisfactorily for all grades of work, whereas in the United States we feel that requirements are better met through a dual system of pitches. Had the British held our view, or conversely, had we held the British view, the few differences that might occur in the resulting British and American series could easily have been adjusted through conference.

With reference to the second point and with special reference to the second paragraph of p. 1008 and the last paragraph of the first column of p. 1009, The Journal, November 1918, I would offer the following comment: The time has come, I believe, when we must, in a specification, do more than prescribe the profile that forms the ideal boundary between the external and internal thread. We should, I believe, specify the maximum tool profile, i.e., that profile of the tool which when new will produce a screw with the deepest root and the highest crest; as well as profiles of the "go" gages, which should be so shaped that the product gaged by them will not trespass upon the standard profile. Provision is thus made for a definite maximum clearance at the crest and root, and also for wear of the crest of the tool.

My experience with reference to the action of the thread tool at its root does not agree entirely with that of the author. Outlines of screw threads, both external and internal, on an enlarged scale of 50:1 indicate that the thread tool at its root suffers very little if any wear in service, as the crests of the thread are fairly true to the theoretical profile where it has been entirely formed by the thread tool. Where the bore of the nut has been enlarged and the outside diameter of the screw has been reduced so that the threading tool removes nothing from the crest of the resulting thread, the metal at the edges of the crest, instead of being removed, is built up or spun up, so that they are slightly higher than the surface at the middle of the crest. Observation also shows that the thread tool has under such conditions cut the thread fairly concentric with the bore of the nut and the body of the screw.

With the provisions made for clearance as cited above, I believe (1) that considerable eccentricity of the thread with reference to the bore or body diameter is permissible and (2) that much latitude may be allowed with reference to the shape of the tool crest. In fact, it is immaterial except as to the relative "life" of the thread tool, whether the crests of the tool be of the Sellers or Whitworth shape. My personal experience, however, is the ground for my preference for a thread having flattened crests and roots. The reasons for this opinion are given in a paper on the Screw Thread Situation in Great Britain and America which I read before the Society of Automotive Engineers.

Thread-Gage Making and Testing

The next papers presented were by Frank O. Wells on Present Practice in Thread-Gage Making and by H. L. Van Keuren on the Measurement of Thread Gages. These papers are both comprehensive and practical, representing as they do the most advanced practice. Considerable discussion followed.

As a preface to his paper, Mr. Van Keuren said: "Some time ago the Gage Committee of the The American Society of Mechanical Engineers recommended that there be a central place for the certification of master gages, and that as Congress had provided a fund for this purpose for the Bureau of Standards, and as the Bureau of Standards was organized and ready to handle the work, it should be the central place for the carrying on of this work. It is of interest, therefore, that members of the Society should know some of the developments which have taken place there."

H. J. Bingham Powell[1] (written). The number of gages inspected during the last few months by the U. S. Bureau of Air-

[1] Officer in Charge of the Joint Gage Laboratories of the U. S. Bureau of Aircraft Production and of the British War Mission.

craft Production and of the British War Mission is from 15,000 to 18,000 a month, and a program of a thousand gages a day was under consideration when the war terminated. Over 80 per cent of the gages were screw gages, with the low tolerances of two ten-thousandths of an inch on the pitch diameter and the same figure for the maximum lead error. The other gages were the complex form, flat and angle gages used in aircraft engines and aeroplane inspection generally. We employ girls for the work as far as possible, men only being needed for the more complex gages and where experience in gage making was necessary, such as in the visual inspection, etc. The girls have given most admirable service and have been found to be fully qualified by their patience, steady work and light touch for dealing with the very delicate instruments we use. Our instruments have been especially designed, bearing in mind the unskilled workers who had to use them, and are practically "automatic" in action.

For instance, our lead-measuring machine shows the correct reading to within two one-hundred thousandths of an inch by the swing of a galvanometer needle. Ten machines deal with 500 gages a day, with errors in readings almost unknown. The National Physical Laboratory pitch-diameter machine described by Mr. Van Keuren has been modified by us by fixing an attachment to it which puts a constant load on the wires and does away with the feel of the micrometer, a small lamp extinguishing when the reading is correct. The results given by the different pitch-diameter machines are thus obtained under identical conditions of loading of the wires and pressure on the micrometer spindle: the latter having on its barrel a divided wheel by which readings can be taken to a fraction of a ten-thousandth of an inch.

The horizontal type of the National Physical Laboratory optical projection lantern is used with a lens that gives a correct field 8 ft. in diameter. We photograph all the plug gages and the casts of ring gages by means of a special apparatus which takes less than one minute to operate. The photographs are measured for angle of thread and checked for form by placing them over suitably engraved glass screens illuminated from underneath.

To take casts of ring gages we have a special appliance that does the work in a few seconds. All this apparatus has been designed for dealing with our large number of gages with expediency and accuracy without having to employ highly skilled mechanics who in war time can be better employed elsewhere.

Data from Frankford Arsenal

C. P. Colburn[1] (written). The object of this discussion is to show how methods of precise measurement may be simplified and adapted to practical use.

Measurement of Pitch Diameter of 60-deg. Thread by 3-Wire System

The usual trigonometric formulæ for determining the correct wire size and the over wire dimension for determining pitch diameter of thread gages and taps is a problem too deep in mathematics for many shop mechanics. The formulæ here given are intended for the workman who is not a mathematician, but who finds it necessary to make calculations due to the fact that drawings are not generally arranged to show over wire measurements and the correct size of wire which should be used to obtain the best results.

The following formulæ will render equally correct results and may be used for all styles of 60-deg. threads by any one who has a knowledge of ordinary arithmetic. In both instances the size of wire used should be such that the points of tangency will lie in the pitch line.

Diameter of Wire. (See Fig. 1.) The diameter of wire which will touch the sides of the thread at the pitch line = $\frac{2}{3}$ depth of a sharp V thread. The depth is determined by dividing $\frac{1}{2}$ the decimal pitch by the tangent of $\frac{1}{2}$ the included angle, or by 0.57735.

[1] Major, Ord. Dept., U. S. A.; Gage Dept., Frankford Arsenal.

$$W = \frac{2}{3}D \qquad D = \frac{H}{\tan 30°}$$

$$W = \frac{P\ (\text{Decimal})}{1.7321}$$

where

P = pitch

W = diam. of wire

H = $\frac{1}{2}$ pitch

D = depth of sharp V

Pitch Diameter. The pitch diameter of a thread gage or a tap

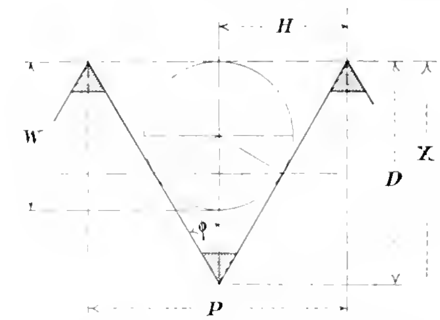

Fig. 1 Diameter of Wire to Touch Threads at Pitch Line

can be computed by substituting the measurement over the wires and the mean diameter of wire in the formula

$$PD = X - 1.5W$$

where

PD = pitch diam.

X = measurement over wires

W = mean diam. of wires.

The dimension over the wires is found by adding 1.5 times the mean diameter of the wires to the pitch diameter as given in Fig. 1. Any variations from the measurements thus found indicate over or under size at pitch diameter.

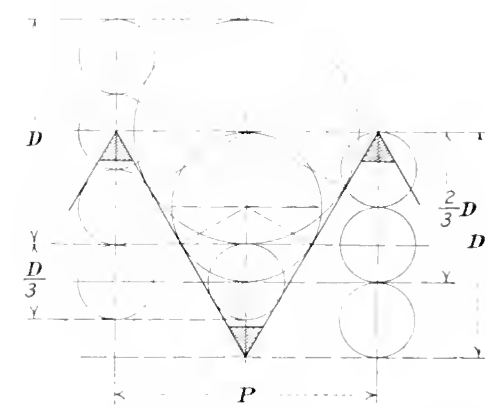

Fig. 2 Checking Angle on 60-deg. Threads with Standard Best Wires

Test for Angle of 60-Deg. Thread by Use of Wires

The angle of a 60-deg. thread can be tested by using two wires, the diameter of the larger being equal to the single depth of a sharp V thread and the smaller equal to $\frac{1}{3}$ the single depth of the sharp thread. (See Fig. 2.) Knowing the diameter of the wire, which is tangent to the sides of the thread at the pitch line, the diameter of the large wire can be found by multiplying that value by 3 and dividing by 2. The diameter of the small wire is equal to $\frac{1}{3}$ the diameter of the large wire.

When both wires are placed in the thread and touching the sides of the thread, they will be tangent to each other at the pitch line.

To make this system practical for the checking of angles, the

small wire ($D/3$) should be made in two sizes and used as a "go" and "no go" gage. The sizes of "go" and "no go" wires are determined by the allowable tolerance of the angle. The large wire being held against the angle of the thread will permit the small "go" wire to pass underneath. The "no go" wire should not pass, if the angle is within the specified tolerance.

The larger wire touches slightly below the top of the U. S. Standard thread approximately a distance equaling the flat on the top of thread. The small wire lies on the angle at the same distance from the root of the thread. This makes the approximate range of the angle test about $^3/_4$ the depth of the thread.

The writer recommends that working drawings show methods of inspection and all necessary dimensions. This will obviate many errors, usually resulting in the complete loss of the article. This method also reduces the cost of computation, which would be made once, whereas in the present practice the shop mechanic and inspector usually work separately, thus naturally increasing the cost of the product.

Luther D. Burlingame referred to the joint meeting of the Society with the Institution of Mechanical Engineers in England in 1910, when Sir Richard Glazebrook was kind enough to say that, while Great Britain had shown the way toward standardization and toward interchangeability of parts, it had been the part of America to put that into practice. Now the table is turned, and as we read of what has been accomplished at the Bureau of Standards, we find that we have ourselves been learning the advanced work which had been done in Great Britain so that the two great Anglo-Saxon peoples are working together, each to help the other in carrying these matters toward solution. We must remember, however, that the final question is not that of gages, but of knowing that the final product will be workable and satisfactory.

He said that Mr. Wells has expressed the thought that there are so many steps in the question of tolerances, that a much more complicated problem is presented than would seem on the face of it. As an aid to this, however, we have the possibility of combining the errors of lead and diameter in such a way that an increased error of diameter may be compensated for by an error in lead, and as far as we can take advantage of this condition we can increase our tolerances; but the last word will not be said in this matter until we have means of combining measurements so that we know what is the combined error of diameter and lead.

H. H. Suplee, in alluding to the praise Mr. Hartness had bestowed upon the work of the National Physical Laboratory and the Bureau of Standards, reminded his hearers that the latter was established as a result of a paper presented before this Society some 25 years ago by James W. See, of Hamilton, Ohio. Mr. See wrote a paper on standards, and after he had presented it, he recommended that there should be a Bureau of Standards established by this Government. A committee of this Society went to Washington and the Bureau of Standards was established. The National Physical Laboratory was started after that, but the whole idea of the Bureau of Standards originated in this Society.

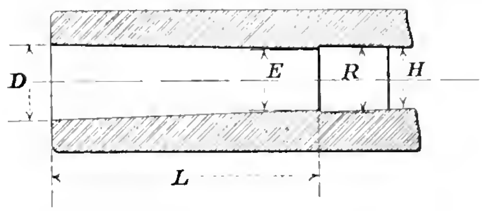
"There was a movement years ago," he wrote, "to abolish all numbered sizes for any purpose whatever, and I think it should be revived. The late James Christie was active in the promulgation of this idea, which I found quite easy to follow, because the actual size was always the thing desired, while the arbitrary number given to it was a matter of no interest whatever.

"I suggest, therefore, as an amendment to the system proposed that the number of the taper be omitted, and that the length of taper be made three times the diameter at large end, instead of twice plus four."

William Bacon. (Written.) During the past three years the Reed-Prentice Company has made a study of the subject of lathe centers and has adopted for its use a formula based on the Jarno taper.

The taper adopted is 0.6 in. per ft.; length = 2 × diameter of large end + $1^3/_4$ in., and the number of taper is designated by diameter × 8. The following table gives the dimensions for the lathes made by this company.

DIMENSIONS OF LATHE-SPINDLE TAPERS



(All dimensions in inches. No. of taper = $D \times 8$; $L = 2D + 1.75$ in., $E = D - 0.05L$; $R = E + \frac{1}{32}$ in.)

No.	Lathe Size, Inches		D	E	L	R	H

STANDARD TAPERS FOR SHANKS AND SOCKETS

The final paper by Luther D. Burlingame on Standards for Large Taper Shanks and Sockets, was briefly discussed.

Wilfred Lewis wrote in approval of the $^3/_4$ in. per foot taper for large taper shanks and sockets, but was not so sure about the lengths recommended—he did not see why all shanks and sockets should not be similar in every respect. He was disposed to agree with Mr. Walters of the Westinghouse Company in advising a length of three times the diameter.

He thought Mr. Burlingame had done well in his choice of sizes: 4, 5, 6, 7, and their multiples by two, making 8, 10, 12, 14; thus forming the basis for a rational progression in sizes, stepping up again to 16, 20, 24, 28, or down by division to 2, 2.5, 3, 3.5 and so on, as far as may be desired. He did not believe, however, in designating these by the numbers 19, 20, 21, etc., as proposed. No. 19, also, conflicts with No. 19 of the Jarno taper. He would prefer to designate the tapers by the sizes themselves.

The timely address by Dr. Frederick G. Cottrell, Chief Metallurgist of the Bureau of Mines, on The Liquefaction and Separation of Gases, an abstract of which appears elsewhere in this number, records one of the most important industrial developments of the past year, i. e., the low-cost production of helium for use in dirigible and observation balloons. During the period of the war, so Doctor Cottrell relates, the word "argon" was used in all correspondence as a code term for helium. While argon and helium are both inert gases, argon is too heavy for use in balloons, and is familiar because of its extensive use in the incandescent-lamp industry. It was thought, therefore, that the term would be a particularly effective camouflage, which actually proved to be the case, since there is evidence of the two words being confused in the public's mind. Doctor Cottrell urges, now that all secrecy has been abandoned, that the correct term, helium, be used whenever referring to the subject.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of MECHANICAL ENGINEERING by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in THE JOURNAL, or brief articles of current interest to mechanical engineers.

"Over the Top" in France

TO THE EDITOR:

I am in receipt of your letter of the 31st ult., and will say that on my return to the States I may be able to contribute some articles from my experiences and observations over here that will be of interest for THE JOURNAL and I will try to arrange this. I am first and last for anything that will be of interest and aid to anyone in any of the engineering lines.

My regiment spent the last three months of hostilities in front-line work without a day's rest, and on two or three occasions was on duty three days and nights without rest or sleep—then a four hours' rest and back into the big game—not a murmur nor a complaint. That is a good sample of our boys as I have seen them. They have done wonders which in many other countries would call for lavish praise and commendation, but which with us was merely a part of the day's work. As one of the Corps Engineer Officers, 1st Army Corps, First Army, I saw nine different divisions go in and out, and in action in one of the most heavily fortified or organized sections of the front. Their deeds of heroism were legion and probably few of them will be chronicled; but I have seen them chronicled on the terrain of France, whether it was down the slopes of Hills 304 and 295 and over the summit of Monfaucon, or in the Bois de Cheppy—names that have stood forth in letters of fire and blood since February, 1916, when the German ambitious attempt to take Verdun started. From the Swiss border to the North Sea you will find at intervals little plots filled with crosses bearing metal disks with such names as Ferrati, Grunsky, Jones, Murphy and Schuster—damned good Americans, all of them.

When I landed in France in June things were gloomy. The German offensive was still on and going good. The Allies were standing sledge-hammer blows and had been for four years. They had seen month after month and year after year of deadly fighting and were tired. It seemed as if they must be forced to acknowledge defeat before the United States could bring her resources to bear. They knew we were sending men, and thought that they would help some by putting a regiment here and there, but they did not believe that such a thing as an American Army could be possible for another year.

The "Pershing System" had been under way for about a year when I landed in France in June, and while this "system" had not been trumpeted about, there was one man at least who knew what was being done, and that was the American Commander-in-Chief. In the dark days when the Germans swept forward to the Marne for the second time, General Pershing placed all the resources of the American Army at the disposal of Marshal Foch. No doubt our allies expected a division here and there sandwiched in between veteran troops to help some, but if the truth were acknowledged that is about all they expected. Then came Chateau-Thierry and Belleau Wood, and our allies stirred. By chance, when the Germans crossed the Marne with Paris as an objective, two of our divisions were directly between them and their objective. The Germans began their "infiltration" methods that had been netting them gains everywhere, but our divisions opened at 800 yards with a deadly, aimed rifle fire that wrecked the German system. Aimed, accurate rifle fire in the heat of battle amazed our allies.

When the accurate rifle fire had shattered attack after attack, our divisions went forward with the bayonet with an enthusiasm and an earnestness that surprised the French and disheartened the Germans. Then followed the advance from the Marne to the Vesle, and our men occupied the hottest part of the line and held their own with the French veterans. Some divisions of the famous Prussian Guards were sent in to stop the "schweinhund" Americans at all costs, but they were cut to pieces just as badly as if they had been only Landwehr divisions. It may have been that our boys had been too busy practicing the art of war to study up on the Prussian Guards and didn't know they were "famous," but my impression is they simply didn't give a rap—they were simply Boche, and being Boche were due to get cut up.

The fighting on the Marne and to the Vesle was not only a great victory, but it was more than that. Our allies were introduced to the American divisions as fighting units that could hold up their end under any conditions. The "pep" and the unbounded enthusiasm of the American soldier became infectious. A little of the tired and gloomy looks began to disappear. General Pershing had built his system around his conception of the American man as a soldier, and American manhood did not fail him.

In August the organization of the First American Army was announced. General Pershing assembled his veteran divisions and some that were comparatively new. On September 12 the world learned that the First American Army had made an independent move—a stroke against the famous St. Mihiel salient that had been a thorn in the side of France for four years. In less than a week this entire salient was wiped out and 15,000 Germans captured, together with hundreds of guns and enormous stores. Thus the First American Army made its bow to the world. While the St. Mihiel operations were conducted by the First Army, yet it was not all there by any means, but it was assembling and taking over the lines in the Argonne-Meuse sector and the heights north of Verdun, and on September 26 the First Army went "over the top" on a forty-mile front in the greatest military offensive the world has ever seen.

The pinching out of the St. Mihiel salient was only a prelude, a curtain raiser, for the "main act" that was only to end when Germany surrendered unconditionally. The sides of the St. Mihiel salient were backed by natural positions that were strong in themselves and sections of the German line from St. Mihiel to Pont-à-Mousson were lined with a network of concrete machine-gun positions ("pill boxes"), so the whole salient was a sort of fortress that had resisted all attempt at capture for four years. As for the line held by the First American Army from west of the Argonne Forest to the north of Verdun, this front was as highly organized and protected by every sort of means the Germans could devise. During the four-and-a-half years of the war this section of the line had become almost a vast graveyard—of German hopes as well as of men. Military authorities have estimated that the eight months' effort of the Germans to take Verdun in 1916 cost them 400,000 to 500,000 in killed alone, and the French half as many. Viewing the country from the heights of Monfaucon to the south to Hill 295 (Le Mort Homme) and Hill 304, the only expression I could frame to describe it was a "scene of abominable desolation" as expressed in the Bible—it was pathetic—it was awful.

Recently, since our Army has gone forward to German soil, I stood on the summit of Monfaucon and looked over the country toward Verdun where shells by the million had poured and where men by the hundreds of thousands had died—died for what? only to satisfy the insane desires of a world-power Kaiser to perpetuate a rotten dynasty. This day, in the expanse of country as far as I could see there was not a single living person or thing. The ground for miles was upheaved and torn as by a gigantic earthquake. The ruins of the destroyed towns were dead. It seemed too unreal to be true—just a dead world in which all living beings had returned to dust. There is a pathetic grandeur about these "dead" towns that have been so ruthlessly destroyed. They seem

Members who were in attendance at the Spring Meeting at Worcester will remember with pleasure the address given at that time by Lieut.-Colonel J. Edward Cassidy, U. S. A., on Conditions and Requirements of Warfare, which so electrified the audience and enthused them with regard to the accomplishments of the engineer in the war. Lieut.-Colonel Cassidy was then stationed at Camp Devens, but shortly after went abroad with the Expeditionary Forces.

to say that they have given their all for France and plead that their naked ruins be hidden from the sight of man.

But not all destroyed towns are "dead"—some proclaim their immortality and defy the human agency to destroy them. The town of Monfaucon stands on a hill some 40 meters higher than any of the surrounding country, and the ruins of the town stand forth against the skyline for a great many miles around, and seem to me to be a deathless monument that proclaims its martyrdom but still holds a taunt and a dare to the German to do his worst. Verdun, I call "The City that Could not Die." A city that was so much of a temptation to the Boche as to cause him to waste his soldiers by the hundreds of thousands, and a city that caused the French poilu to perform superhuman deeds in its defense, cannot be an ordinary city. It was a tantalizinz will-of-the-wisp, a sort of end of the rainbow, always just a little distance ahead but always out of reach—to the Germans; and to the French, something too sacred to be permitted to fall into the bloody hands of the invader. Shelled continually day after day and year after year for more than four years, until the grip of the Germans on the approaches to the city was broken forever by the First American Army, "The City that Could not Die," though torn by shells and partly wrecked, stands today and will stand for generations to come as a monument to the valor of the soldiers who defended it so well.

I trust that some writer or historian who can paint word pictures of these ravished towns and cities of France and Belgium will study them while they are yet unchanged, so as to record their history for generations yet unborn.

J. Edward Cassidy,
Lieut.-Colonel, Engineers, U. S. A.

Committee on Aims and Organization

To the Editor:

During the discussion of the report of the recently appointed Committee on Aims and Organization at the Annual Meeting, Mr. Spencer Miller—a member of the Council—urged that as a supplement to all that has been said and written on a re-aimed and reorganized A.S.M.E., there should be presented a terse statement of definite steps to be taken in effecting the desired result. "Let them give us 'fourteen' points," was his appeal, as I recall it.

Each member of the Society would probably have his own reply to such a request. No such expression of opinion should be without value in our further discussion. May I submit one group of definite suggestions, each of which appears to me to be both possible and important and some almost vital to our future progress.

Any statement of aims and purposes either for an individual or a society should be elevated in tone and broad in scope. The times invite a position of influence and a breadth of usefulness for the engineer—and especially the mechanical engineer—nowhere suggested in our official pronouncements. Hence fundamental to all genuine progress we should have:

1 *A Restatement of Our Aims and Objects.* Our present activities both in quality and scope transcend the limitations of the Constitution. It would be better if this condition could be reversed. Our Constitution should present a goal to which we could aspire rather than set limits which we have long since passed.

A growing measure of democracy must be developed in all our affairs as for instance through:

2 *Publicity.* Provide at every annual and semi-annual meeting a session at which the affairs of our Society can be discussed with reasonable informality and until everybody is reasonably satisfied; encourage the publication of several pages of such letters as this—not about technical matters but about the life of the Society—in each issue of Mechanical Engineering.

3 *Encouragement of Younger Members.* Grant junior members the right to vote and hold office. The 21-to-30-year-old men vote in city, state and nation. Young doctors vote in the American Medical Association. Why not take a chance on the young engineers? We need both their enthusiasm and their point of view. This class of members will always be in a hopeless minority.

4 *Home Rule.* Remove every possible restraint on freedom of action on the part of local branches.

5 *Popular Election of Officers.* Now that the Nominating Committee is to be elected, put some thought and energy into getting everybody into the play. No mere change in machinery will do it. The proposed system may easily give results less beneficial to the Society than the one it supersedes. Publish a 100-word sketch about each candidate for office. Let the members know for whom they are voting.

6 *Appeals.* Provide for a review of all administrative acts, such as those of the Meetings Committee in rejecting papers and of the Membership Committee in rejecting members. This machinery will not often be used, but its existence will provide a safeguard and remove one of the causes of bitter dissatisfaction in the past.

The prestige of the engineering profession will be enhanced not only as we render increased service but also as we raise our standards of professional conduct, hence we must provide:

7 *A New Code of Ethics.* At one of the sessions of the Worcester meeting a vote in favor of a more advanced code was passed.

8 *Means of Enforcing Standards of Professional Practice.* Such administrative methods are already in force with the American Institute of Architects and work satisfactorily.

Everybody admits that this is the "day of the engineer," and yet as a profession we get almost no recognition because we are cut up into organizations representing divisions and subdivisions of the engineering profession. We should come out frankly in favor of:

9 *One National Engineering Society.* Work for it in season and out of season, and above all until it is accomplished we should do nothing for our own advancement which will make its attainment more difficult.

Certain of our activities require to be taken more seriously—as for instance—

10 *Employment.* In view of some of the work on the classification of the personnel in the Army and the "hiring and firing" methods used by forward-thinking industrial concerns, the employment work of our great engineering societies has been crude indeed.

11 *Public Engineering.* The education on engineering matters which our profession affords the public through its national and its local societies is almost *nil*, as compared for instance with that rendered by the medical and even the architectural profession. Special emphasis should be placed on assistance to be rendered to public officials having engineering for their field.

12 *Engineering Internationalism.* Engineers—and our Society especially—have done much to promote friendly international relations. But the issue of the war has emphasized the importance of such work and we should lay our plans for the future along the broadest lines.

An adequate administrative machine is required for any enterprise. A single executive leader is an essential cog in any such machine. Responsibility implies authority and real authority is not conferred through a title. We need in the A.S.M.E.:

13 *A Salaried Administrator with Power.* Call him Secretary, Executive Secretary, Managing Director or what you like. He must be the working head of the Society elected by the Council and holding office while he gets results. His authority or responsibility should correspond to that of the president of a corporation.

14 "*Chairman of the Board.*" This is the function which the President of the Society, elected annually, should be given. We have never had a president who gave enough time to the work of the Society to warrant his assuming the executive and administrative leadership of its affairs. The one-year term would make success impossible.

Our Society has had a splendid part in the development of the art and science of engineering. The times demand both broad vision and indomitable purpose in the application of engineering knowledge to the needs of mankind. Given both, our association of 10,000 members may play a master rôle in the years just ahead.

Morris Llewellyn Cooke.

A Useful Industrial Diagram

To the Editor:

Many methods of showing in diagrammatic form the time-output and similar data are in general use.

The most general arrangement is that shown by Fig. 1, which illustrates monthly fluctuations in output. The output may be

in tons of castings, numbers of automobiles, or may be profit realized monthly, or anything else related to time.

As a record of the past a diagram such as this leaves nothing to be desired.

The executive, however, whether he deal with materials or dollars, is not satisfied with a mere record of what has occurred in the past, but he wants to use the past experience as a basis for consideration or production of the future. It is possible to extend the recording curve of Fig. 1 to indicate a future probability, but this is neither safe nor simple.

Plotting the same data in somewhat different form as in Fig. 2

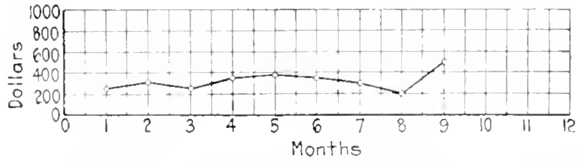

Fig. 1 Diagram Showing Monthly Fluctuations in Output

answers every question as to the past and also readily predicts the probabilities of the future.

To deal with something concrete, let us say that it is the profits of the business that are being examined, that these are being ascertained monthly, that the corresponding result for the year is desired and that the prediction is to be brought up to date or corrected each month.

In Fig. 2 each month's earnings are plotted to a curve duplicating the usual one illustrated in Fig. 1. This is the lower curve shown.

Over each month there is plotted the total profit to date. For instance, January shows \$250, February, \$300, and the total there-

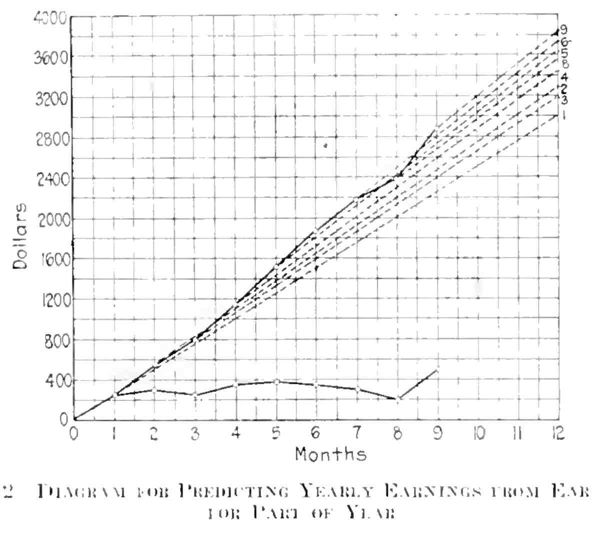

Fig. 2 Diagram for Predicting Yearly Earnings from Earnings for Part of Year

fore to date is \$550. These are shown by the upper solid curve.

To predict the probable profit for the year it is only necessary to draw a line from zero through the total earnings to date and to continue that line to the twelfth month; for example, the total profit by the end of the fourth month was \$1150; the projection shows \$3450 as the probable rate of profit for the year resulting from the first four months. An examination of the diagram shows that there is an improvement in the second and third months over the first month and an improvement in rate by the end of the fourth month over the previous months. By the eighth month, however, the rate had fallen off from that of the fifth, sixth and seventh months, as is clear from the production line for the eighth month falling below that of these previous three months. The ninth month, however, showed clearly an improvement in the rate to date.

The inclination of the lines giving the totals of each month also furnishes useful data. It is clear that if these lines all have the same slope, the increase from month to month is then equal. A lesser angle shows a decrease in monthly earnings and a greater angle shows a decrease in monthly earnings.

The most useful element of this form of plot, however, is the projection into the future and the ability that it gives to instantaneously correct the indications of previous periods by the result of the last period.

Henry Hess.

Philadelphia, Pa.

Power Supply to the A. E. F. in France

In the last of his series of articles in the *Saturday Evening Post* on "Business-Managing War," Isaac F. Marcosson describes the problem of securing power for the many industrial needs of the A. E. F. in France, and of the work in this connection by a member of this Society, Maj. Dugald C. Jackson, Professor of Electrical Engineering at the Massachusetts Institute of Technology. Mr. Marcosson writes:

It must be understood that the A. E. F. is engaged in an immense industrial activity in France. We have enormous car and locomotive erection and repair shops; we build tanks; reconstruct motor transport; salvage endless equipment; occupy hospitals almost without number; operate docks; roast and grind coffee and manufacture chocolate. All this requires power, and every service clamors for it. How do we get it? * * * * *

The general purchasing agent met the emergency by establishing what is known as a technical board, one of the many activities under his supervision. The executive head of this board is Lieut.-Col. Francis E. Drake, who as chief of the control bureau is the chairman of the technical board. The active head, however, is the chief engineer, Maj. Dugald C. Jackson, a widely known consulting engineer with much experience in public utilities in America, who was a member of the faculty of the Massachusetts Institute of Technology. Associated with him from the start has been Capt. Albert B. Cudebec, a specialist in hydroelectric construction, who with Major Jackson was one of the pioneers in American Army power production in France. Gradually they have assembled a group of more than forty engineers who in civil life built dams and irrigation projects and installed power plants from the Atlantic to the Pacific. The technical board is a sort of congress of experts which, in the face of almost innumerable obstacles, has furnished the juice to drive the Army's many-sided industries.

Since it was extremely difficult to get complete new power plants from America, the board set about to develop and adapt existing French power establishments to the American needs. Wherever an uncompleted French power station was discovered American construction gangs were put to work to complete it. Every possible makeshift was employed, all to the end that power be secured. The general purchasing agent learned that some Swiss turbines intended for Russia had not been shipped. They were immediately secured and installed by American engineers in a French power station. Our purchasing representatives scoured all Europe for installations. A complete plant was discovered in Portugal. Within sixty days it was driving machinery up in the advanced section. The technical knowledge required for all this adjusting and adapting frequently had to be supplemented by tact of the highest order, for the reason that these undertakings involved rival French commercial interests, which were jealous of their prerogatives and which had to be reconciled to the larger obligation that both France and America were being served by this expansion.

The technical board is on the job day and night and it has met emergencies with a degree of swiftness not surpassed on the firing line. Here is a concrete story that will show the kind of propositions that are put up to it: On September seventeenth last, Major Jackson received the following telegram from G-4—the army coördinator—at Tours: "Get 3000-kilowatt plant in Europe." It was intended for immediate and urgent use at a large base port that we are using. Within a week a plant had been located in England and in a month it was installed in France.

A huge map that hangs in Major Jackson's office at the Elysée Palace Hotel gives a comprehensive idea of the empire of power that we have helped to develop in France. We use power in exactly three hundred and twenty-eight localities. Each one of these installations is shown in a concrete way. The master color for steam-generating plants is green, and hydroelectric service is in blue. Whenever the service is all-American the indication is surrounded by a red circle. In addition to this every army activity has its own color. An orange square denotes a bakery; a black square a salvage depot; a green-and-white square an aviation center; three white squares reveal a tank-building plant, and so on.

This American-developed power area means a great deal more than driving machinery in A. E. F. bakeries, salvage depots, air-service stations and machine shops. It has a significance for peace not to be overestimated. Combined with the utilization of water power, which is incorporated into our general power scheme, an immense section of France is likely to be diverted after the war from agriculture to industry. The brilliant imagination of the French has caught the spirit of what adequate power means. In this inevitable evolution you see one of the many permanent results of the advent of the American Army.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

AERONAUTICS

STABILITY OF A PARACHUTE, S. Brodetsky (*Tôhoku Math. J.* 14, pp. 116-123, Aug. 1918). Investigates the equations of motion of a falling parachute with its load, assuming these to be rigidly connected and not to possess independent oscillations. The conditions for stability are that $A^2 > B$, and D, the depth of the center of gravity of the passenger below the center of gravity of the parachute itself, must lie between the values—

$$\tfrac{1}{2}(1-m)^{-1}\left\{A \pm \sqrt{A^2 - B}\right\}$$

Here $A = a/\rho$ and $B = 4\,[(1-m)/m]\,[(1-m)k_1^2 + mk_2^2 - Ad_1]$; $m = W_2/(W_1 + W_2)$, where W_1 is the weight of the umbrella and W_2 that of the passenger; $W_1k_1^2$ and $W_2k_2^2$ are respectively the moments of inertia of the umbrella and the passenger about parallel axes through their respective centers of gravity and parallel to the plane of the umbrella, a is the radius of the umbrella and ρ is a constant depending on its shape (for a circular plate ρ is probably nearly equal to 4). *Science Abstracts,* Section A—Physics, vol. 21, pt. 11, Nov. 30, 1918 (No. 251), p. 449, *t*)

CEMENT AND CONCRETE

POTASH IN CEMENT-MILL DUST, Albert R. Merz and Wm. H. Ross. In view of the importance of the recovery of potash from the flue dust of cement mills, the following information as to the nature of the recombined potash thus recovered may be of interest.

The analyses have shown that in some cases potash recovered from the dust was found to consist in part of a material insoluble in acids, while its other part was soluble in acids but insoluble in water.

Further, it was found that in the oil-fired plant of the Riverside Portland Cement Company the greater part of the potash in the dust was readily soluble in water, while in dust collected at plants where coal is used for fuel it was found that the greater part of the total potash was acid-soluble, which greatly reduces its value for use as a fertilizer.

The present article discusses the origin of the water-insoluble potash in the dust and comes to the conclusion that its presence is due first to the ash of the coal and the dust carried over mechanically, but also possibly to the fact that a certain portion of the potash has been volatilized in the process of burning and has undergone a recombination during its passage from the kiln.

As a practical suggestion it is stated to be probable that the proportion of recombined potash in those dusts which contain free carbon might be reduced to some extent if more of an oxidizing atmosphere was maintained in the kilns during the burning of the cement.

Also, the experiments described in the article lead one to believe that the addition to the raw mix of a salt of sodium, such as sodium chloride or common salt, would bring about a reduction of the recombined potash such as has actually been observed at the plant of the Security Cement and Lime Company. Further, little recombination of potash with coal ash takes place in the carbon-free mixtures when lime is present.

Finally, the greater the amount of potash volatilized the lower will be the proportion that will undergo recombination in the dust.

The article is based on work carried out at the Bureau of Soils, U. S. Department of Agriculture, Washington, D. C. (*The Journal of Industrial and Engineering Chemistry,* vol. 11, no. 1, January 1, 1919, pp. 39-45, *tpA*)

ENGINEERING MATERIALS

Testing Car-Wheel and Locomotive Tires

FALLING-WEIGHT TEST ON RAILWAY TIRES, J. H. G. Monypenny. Discussion of the reliability of the falling-weight test as showing the conditions of a railroad tire.

The writer explains that the conditions in the ingot from which the tire is rolled, namely, the roughness of the surface, especially toward the top of the ingot, are such that any object rolled from the rough part of the ingot is apt to have an imperfect surface and to be shelly and roaky. The surface of the ingot may be folded or pitted for many reasons and small holes may be present in an ingot immediately below the skin. These irregularities would be reproduced in one way or another as surface defects in the rolled tire—usually as small seams and also as laps, these latter due to negligent forging. Similar defects might be found on the inside surface of the tire, but they rarely occur there unless badly piped ingots are used.

Now, the character of the falling-weight test is such that the tire is severely distorted in certain parts, while in others it is hardly deformed at all. The test consists in placing the tire in a running position on a heavy steel block weighing from five tons up, supported on a rigid foundation. A tup generally weighing one ton is allowed to fall freely on to it from gradually increasing heights until the tire has given, without fracture, a certain minimum deflection, the amount of which depends on the diameter and thickness of the tire and the character of the steel of which it is made.

It is of importance to determine whether the small superficial cracks which have been found to have but little influence on the actual performance of the tire will affect results in the falling-weight test.

To determine this, small bars 0.45 in. in diameter were turned from tire steel. The first bar was not notched; the second bar was notched on one side only to a depth of 0.013 in. Other bars were notched similarly to the depth stated in Table 1. The bars were gripped in a vise and broken by the impact of a pendulum hammer (Izod test). The energy absorbed in breaking the bars is reported in the table. A comparison of the first two lines shows clearly how sensitive tire steel is to even a minute notch, which

would indicate that a tire having a surface defect which is in any way equivalent to a notch is liable to break prematurely under the drop test if the part containing this defect should happen to be located in the highly stressed area under the tup.

The writer says that during the past 14 years he has had many opportunities of examining tires which failed under these tests and noticed repeatedly how small a defect was required to cause

TABLE 1 DATA OF IZOD TEST ON BARS CUT FROM TIRE STEEL

Depth of notch	Energy absorbed in ft.-lb.
Unnotched	200
0.013 in.	23
0.030 in.	16
0.062 in.	7
0.125 in.	3

a high-tensile-steel tire to break, provided the defect happened to be in a critical section.

On the other hand, he claims that the question as to what influence such a defect would have on the life of a tire if it were undisclosed by the drop test, as frequently happens, can be answered easily.

Car and engine tires are machined on the inside and on the tread and flange and in many cases all over before being put into service and the majority of surface flaws would be completely removed during this operation, while flaws of this nature which have not been so removed would be visible on the machined surface.

The conclusion to which the writer arrives is that a tire should not be drop-tested in the rolled condition when it still carries the sins of the ingot and every other neglect or defect of manufacture. He urges that the drop-testing of tires should be done in such a manner that a tire is tested in the condition in which it is put into service. The only possible objection to this would be the waste of the machining costs if the tire failed to pass the test, but it would prevent the scrapping of good material which now takes place due to the condition stated above.

Attention is also called to another type of flaw, the effect of which is often overlooked. This is due to the series of stamped marks on the front of the tire. While it may be necessary for the railway companies to identify the tires they put into use, it is questionable whether it is equally necessary to have the life history of the tire from its infancy of molten steel onward stamped in half-inch letters round its face.

Steel used for tires is easily broken when notched and it would seem advisable to avoid lettering as far as possible. In fact, the writer shows in a photograph an instance where the fracture has probably been materially helped by the deep stamp marks. These stamp marks affect also the life of the tire as they are not removed during machining, but remain as very favorable places for starting points of cracks. (*Engineering*, vol. 106, no. 2759, November 15, 1918, pp. 545-547, 8 figs., *ep.A*)

Behavior of Hollow Building Tiles Under Strains

TESTS OF HOLLOW BUILDING TILES, Bernard D. Hathcock and Edward Skillman. Originally hollow building tile was used mostly for its fire-resisting properties, but, as its other advantages have become more generally recognized, its range of usefulness has been greatly broadened until today it is an important structural material. And, as a consequence of the rapid growth of its use and the relative lack of definite and reliable information of its strength, the tests described below have been made by the Bureau of Standards.

Tiles are molded of clays which are quite diversified in their properties, and, after drying, are burned in downdraft kilns at a temperature well beyond initial vitrification of the clay, but rarely high enough to complete vitrification. These methods introduce variables, especially of color and porosity, which are of great importance because of their relation to the strength properties of the tiles, and have been given consideration in the classification of the tiles of these tests. It is a well-known fact that in a downdraft kiln the upper courses of the tiles are heated to a higher temperature than the lower ones. This gives the top tile a higher degree of burning, those near mid-height a medium degree of burning, those near the bottom a low degree of burning. In general, the high-burned tiles are dark in color, the medium-burned of medium shade, and the low-burned light. However, this is not always true, for the natural color of some clays or the presence of coloring matter will cause a variation.

The tests of this paper are limited to those of compression and absorption. The total number of those performed is approximately 250, of which the majority were upon tiles in compression. Stress-strain readings were taken upon 114 of these for moduli of elasticity determinations. About 70 absorption tests were made upon samples taken from tiles previously tested in compression. All the tiles were graded according to their color as dark, medium, or light, corresponding to the variations produced as described above. The tiles tested were made, with few exceptions, from clay of the buff-burning variety, and the colors given indicate variations in the buff color.

Previous to testing the tiles, their sectional areas and weights were determined. The former was done by measuring the walls and partitions with calipers and computing the sectional area from these measurements. Then they were capped with plaster of paris, to insure a uniform bearing in the testing machine. Small brass plugs were also set in some of the tiles for compressometer readings. The type of compressometer used was the 6-in. Berry strain gage, and readings were taken with it near the four corners of every tile upon which stress-strain relations were desired. The testing machines used were of the Olsen universal type.

The absorption tests were made upon three samples selected from each tile upon which the absorption determination was desired. The tiles from which these samples were taken had been previously tested, in compression.

The results of the compression tests with moduli determinations show that the strain produced by loading a tile is approximately a linear function of the applied load until failure is approached, or in other words, the modulus of elasticity of a tile is practically constant until failure. This indicates also that there is no definite proportional limit for tile; that is, the proportional limit is coincident with failure.

Tiles were tested on end, on edge and flat, and the results show that in general a tile develops both the greatest unit strength and greatest total strength when it is laid on end. The relation between the moduli of elasticity of tiles and their compressive strengths is somewhat variable, or the tile having the highest modulus of elasticity may not have the greatest strength, but in general, if the modulus of elasticity is high it is to be expected that the compressive strength of the tiles will also be relatively high.

There was found to be no definite relation between the loads at the incipient failure and the maximum loads sustained by the tiles. In some cases the incipient failure occurred early in the tests, but in other tests no notice of failure was observed until the maximum loads were reached.

There is shown to be relationship existing between the colors of the tiles and their compressive strengths and the moduli of elasticity. The dark and medium-burned tiles have about the same relative compressive strengths and moduli of elasticity, while the same properties of light-burned tiles are on an average much lower.

From the results of the absorption tests it was found that the maximum compressive strengths vary approximately inversely with the percentages of absorption. Also the percentages of absorption of the tiles vary with their colors. In general, the darker the tiles the lower the percentages of absorption are likely to be, but this is not always true because either the material or the artificial color of the tiles may often be deceptive in this respect. (Abstract from Technologic Paper No. 120 of the Bureau of Standards; *eA*)

FUELS AND FIRING

Properties of Liberty Fuel and Results of Economy Tests. Some time ago an official statement was given to the press from a bureau of the War Department claiming that a new fuel had been invented by one of the officers of the department.

The basis of the fuel is kerosene treated with a chemical, with the result that its oxygen content is increased so that when the fuel is vaporized and admitted to the engine cylinder there is present some of the oxygen needed for the process of combustion.

Fig. 1 gives the distillation curves of different grades of Liberty fuel. It has a variable specific gravity according to its varying quality. The heat value per gallon is 127,900 B.t.u., which is somewhat higher than that of commercial gasoline. (*Power*, vol. 49, no. 1, January 7, 1919, p. 9, 2 figs., *d*)

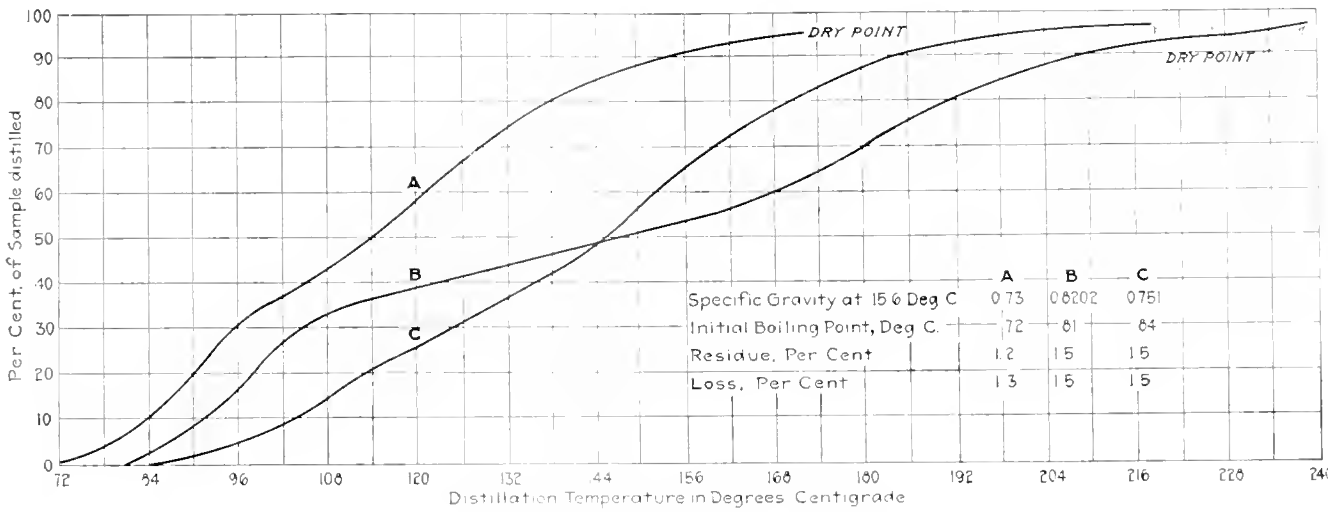

Fig. 1. Distillation Curves of Different Grades of Liberty Fuel

Note:—From data published since the appearance of the article abstracted here, it appears that the so-called Liberty fuel is a mixture, in various proportions, of kerosene and benzol, with addition of slight amounts of amyl acetate.

Efficient Burning of Indiana Coals

Burning Indiana Coal on the Chain Grate, T. A. Marsh, Mem.Am.Soc.M.E. The changes in coal distribution due to war conditions have brought Indiana coal to markets where its characteristics were not understood and the existing furnaces not suitable for efficient burning.

In Table 2 are given the analyses for standard Indiana coals which cover screenings but not run-of-mine or lump coal.

No. 3 coal, while not high in heat value, has the highest percentage of volatile matter and is excellent coal to use to get capacity in furnaces that are deficient in ignition arches or draft. It is not, however, a good coal to store both because it disintegrates easily and because of its high percentage of sulphur.

No. 4 has the greatest commercial value of all Indiana coals. Its heat value is relatively high for a western coal, the sulphur content low and the fixed carbon of such good structure that when used in by-product ovens excellent coke is produced. It is also well adapted for stoker uses, particularly with stokers that agitate the fuel bed.

From the point of view of steam production No. 5 stands at the head of Indiana coals, mainly on account of the large quantity produced, certainty of supply, uniformity and free-burning characteristics. On the other hand, as the coal has practically no clay mixture, the clinker produced is extremely vitreous. The coal is suitable for chain grates but the furnace must be such as to allow good strong ignition.

No. 6 cannot be used at all unless with a proper type of stoker, owing to the large amount of clinker produced and its vitreous structure.

As regards the design of furnaces for use with Indiana coals, the following suggestions are made:

Large grate surfaces should be provided as these coals are relatively inert. Also ample draft must be provided. These coals can be burned at combustion rates of 40 to 45 lb. per sq. ft. of grate area per hour with a draft of 0.4 to 0.5 in. over the fire.

Long, high-pitched ignition arches should also be provided and the furnace volumes should be large. In furnaces where 40 lb. of coal per hour per sq. ft. of grate area are to be burned, the furnace chamber should have a volume of 12 cu. ft. per sq. ft. of grate area, and furnaces even larger are desirable.

As regards the grates, it is claimed that large grates should be installed and the author shows a preference for grates of the chain type as they are claimed to reach excellent efficiencies at from 50 to 75 per cent of rating.

Several types of modern settings capable of producing high ratings and high efficiencies are shown in the illustrations in the original article. A prominent characteristic of all of these settings is the large volume of the furnace—from 12 to 13 cu. ft. per sq. ft. of grate area as compared with 3 to 6 cu. ft. per sq. ft. commonly found prior to 1916.

Analyses of Indiana Screenings

	No. 3 Seam	No. 4 Seam	No. 5 Seam	No. 6 Seam
Moisture	10.8	12.4	10.1	11.0
Volatile matter	35.0	33.2	33.2	31.1
Fixed carbon	36.9	44.2	42.0	41.5
Ash	17.3	10.2	14.7	16.4
B.t.u., commercial	10,400	11,069	10,820	10,540
B.t.u., dry basis	11,670	12,610	12,039	11,730
Sulphur	4.55	1.75	4.27	3.50

From this point of view it is interesting to compare Fig. 2 with Fig. 3. The former represents the designs of a furnace installed under the Stirling type of boiler 12 years ago, and the latter a recent revision of the same furnace. With the original furnace only the better grades of Indiana coals could be used. In the improved setting one continuous arch, 7 ft. 6 in. long, replaces the old sprung arch. After the revision it was found that the lower grades of Indiana coals could be nicely handled, inasmuch as the draft and grate area were adequate and the ignition was better.

From the foregoing discussion the following conclusions are evident:

1 Indiana coals are being and will be extensively used.

2 The characteristics of some of these coals are low fusing

temperature of the ash, great tendency to clinker, and large amount of clinker.

3 These coals give serious clinker trouble when the fuel bed is agitated. Continuous ash removal is preferable. With chain grates in modern furnaces, high capacities and efficiencies can be obtained from all grades of Indiana coal.

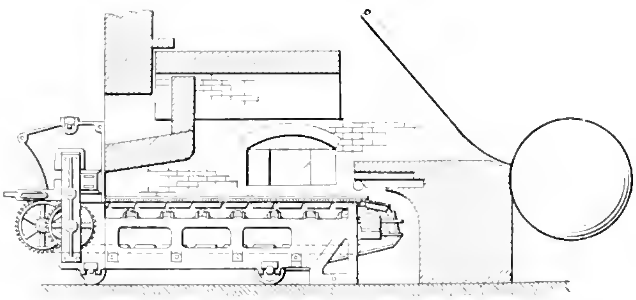

Fig. 2 Furnace Design 12 Years Ago

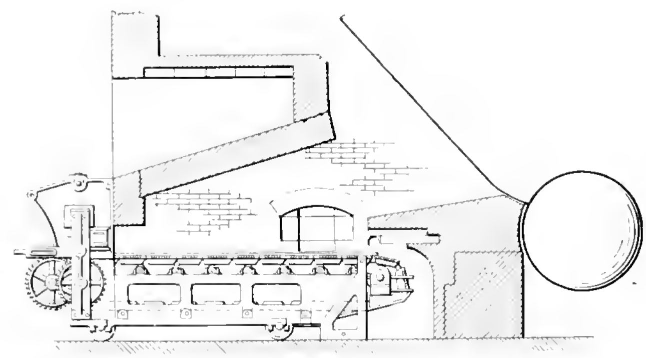

Fig. 3 Revision of Furnace Shown in Fig. 2

4 Existing furnaces permit improvement. Each should be considered in the light of modern engineering knowledge and can be revised, widening the range of coals to include all Indiana seams and increasing the capacity and efficiency under all conditions. (*Power*, vol. 49, no. 1, January 7, 1919, pp. 17-19, 7 figs., *dt*)

Safety Precautions in Use of Cutting Lubricants

Skin Diseases Produced by Cutting Lubricants and Cooling Liquids. This abstract is taken from Bulletin No. 2 of the Scientific and Industrial Research Department, Great Britain, entitled Memorandum on Cutting Lubricants and Cooling Liquids and on Skin Diseases Produced by Lubricants.

The skin disease produced by lubricants are mainly in the nature of oil rashes and may be due to two principal causes:

1 *Blocking of the glands of the hair follicles.* The mixture of oil and dirt blocks the minute openings of these glands and sets up inflammation around the hairs (*folliculitis*). Inflammation starting in this way may lead to suppuration or abscess formation. If many hairs are affected in this way the arm presents the appearance of a crop of red spots with a black spot as a center, or a yellow head in the case of abscess formation.

2. *Mechanical injury to the skin by metallic particles.* This may be caused by the minute metallic particles suspended in the cutting lubricant, and occurs chiefly on the hands where two surfaces are rubbed together, e.g., between fingers. Injury to the skin may also be produced on any part of the hands and arms by wiping with a cloth or rag while the hands or arms are coated with a film of fluid in which metallic particles are suspended. The cuts in the skin allow germs to enter and may lead to septic infection.

The prevention lies in keeping the worker, the lubricant and the machines clean.

Washing accommodations must be provided on a liberal scale for workers in contact with oil. Hot water, soap and scrubbing brushes are essential. Workers should be instructed not to wipe their hands on rags before washing and to avoid washing their hands in the cutting compounds.

Ether soap which dissolves oil has been found useful in preventing inflammation of the hair follicles. Dusting the arms with a powder containing equal parts of starch and zinc oxide before commencing work prevents the action of the oil on the skin.

As regards the lubricant, care must be taken in the handling of the constituents before blending to prevent such changes as formation of free fatty acids. Also the constant removal of metal particles is necessary, which, by the way, cannot be achieved either by such filtration as is provided on the machines or by centrifugal action.

Where straight oils are used their viscosity can be diminished by heat sufficiently to allow the particles to sink without affecting the value of the oil as a lubricant.

It is stated that various antiseptics (e.g., carbolic acid in a proportion of 1 to 2 per cent) have been added to the lubricants to prevent rashes, but the results obtained have not been entirely satisfactory.

Sterilization by heat has also been attempted with apparently satisfactory results, but the actual temperature required to produce this germicidal action in the oil has not yet been determined.

Workers whose hands have been affected by septic infection should not be allowed to work on machines as they are liable to infect the oil with germs, and so infect others.

Certain individuals appear to be particularly susceptible to the action of lubricants. Such persons when found should be removed from contact with oil. (Abstracted through *Mechanical World*, vol. 64, no. 1661, November 1, 1918, pp. 207-208, *gp*)

Elliptical Gears Built Up From Segments, Robt. Mawson, Mem.Am.Soc.M.E. Description of the tools and methods used in machining a special type of elliptic gearing such as used in the movement of the printing bed of the Whitlock "pony" printing press. The gears used for this purpose are built up from segments which have been cut separately and are then bolted to a flange or web.

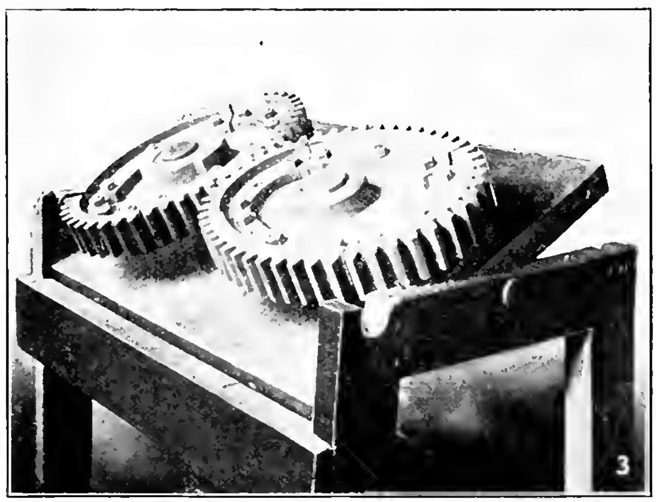

Fig. 4 Assembling Stand for Elliptical Gears

A special jig, shown in the original article, is used for drilling this web. The segments have corresponding jigs to locate the holes necessary to bolt them to the web. Finally, an assembling stand such as shown in Fig. 4 is used, and this can be set at any convenient angle to enable the operator to handle the job in the most efficient manner. The tilting baseplate has two fixed studs located at the proper center distance upon which the flanges or webs are placed and mating segments bolted to each of them. These two segments then receive such slight adjustment as may be necessary and by filing off the high spots are made to work smoothly together. Similar treatment is applied for each addi-

tional segment until the completed gears may be rotated without appreciable backlash or binding.

Since it is absolutely essential that every part of a printing press is in proper relation to every other part, the location of the keyway in these gears is determined after the gears are finished. A special feature employed in this connection is shown in the original article. (*American Machinist*, vol. 50, no. 2, January 9, 1919, pp. 61-62, 4 figs., *e*)

SOLDERS FOR ALUMINUM. The use, serviceability, method of application and composition of solders for aluminum are discussed in the light both of special tests made at the Bureau on commercial and other compositions of solders and of general experience with them. All soldered joints are subject to rapid corrosion and disintegration and are not recommended except where protection from corrosion is provided. Suitable compositions for solders are obtained by the use of tin, with addition of zinc or both zinc and aluminum within wide percentage limits. (Abstract from Bureau of Standards Circular No. 78; *p*)

MARINE ENGINEERING

Reinforced-Concrete Ship of Plate Construction

THE WALLER SYSTEM OF REINFORCED-CONCRETE SHIP CONSTRUCTION, W. Noble Twelvetrees. Description of the methods of ship construction evolved by Capt. J. H. de W. Waller of the British Admiralty, formerly a civil engineer of Dublin, as applied at the Lake Shipyard, Poole.

The characteristic feature of this system is the employment of precast plates in combination with frame members molded *in situ*.

The precast concrete plates are molded in open air on a series of concrete beds. The network of bars for each plate is assembled in a timber frame. The upper face of each plate is troweled while still green and after it has been covered with a coat of whitewash the next plate is molded upon it, the process being repeated until the stack of plates has reached the limit of height for convenient handling.

The work on the slipway is likewise quite simple. The plates forming the sides, bottom and deck of the ship are prepared and seasoned in advance, and therefore have merely to be erected and stayed in place. The only molds required are those for the longitudinal and transverse members of the framework. In order to provide secure anchorage between the several elements the plates are cast with the reinforcing bars projecting along all four sides and arrangements are made for the intermeshing and interlocking of these bars with those of adjacent plates and of members molded *in situ*.

A noteworthy feature of the vessel now under construction is the concentration of the main longitudinal reinforcement for withstanding hogging and sagging stresses in the bilges and gunwales. In fact, the vessel is designed somewhat on the lines of a through girder bridge, the principal longitudinal stresses being taken by the parallel girders constituting the sides of the vessel.

The principal transverse stresses in the deck and bottom are resisted by the transverse frames. The transverse bulkheads at the ends of the holds are built up of precast plates with counterforts extended at the foot and head to a width of 4 ft. 6 in. from the vertical axis. These counterforts are spaced 4 ft. apart transversely, and are of monolithic connection in each case with three of the transverse frames at the top and bottom of the hold. Consequently they form part of the main framework and provide secure support for the decking between or at the ends of the hatchway coamings.

Fig. 5 shows a general section through the frames. Among other things, it exhibits the curved form of the frame, which is a departure from usual practice. It is claimed, however, that this form is not only conducive to strength, but distributes more effectively the deformation of the frames and so reduces the tendency of the skin to rupture.

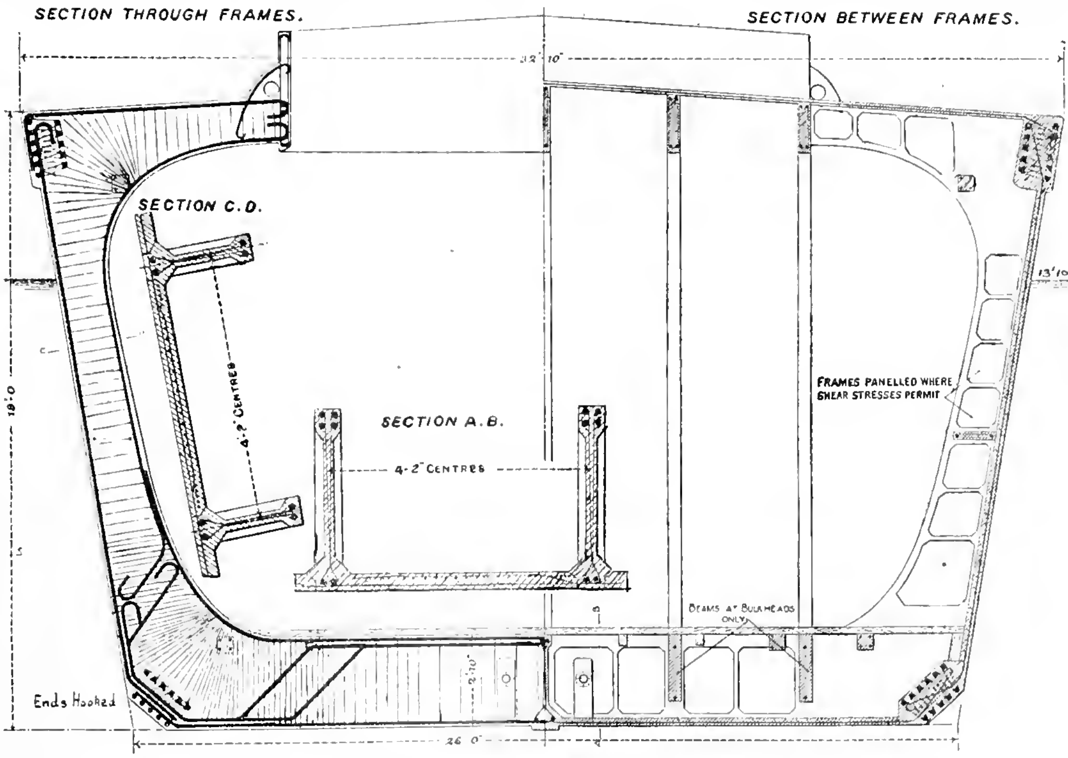

FIG. 5 SECTION THROUGH FRAMES OF WALLER TYPE OF REINFORCED-CONCRETE SHIP

The chief objection against the employment of precast units joined together by frame members molded *in situ* is that the joints may be broken by the hogging, sagging and twisting stresses on the vessel at sea. The reply of the adherents of the precast system is that joints actually exist even in vessels which are theoretically monolithic. The positions of such joints are not predetermined, however, but are governed by circumstances demanding the interruption of concreting work from time to time, and are therefore in a less favorable position than joints in the precast system, the location of which is always predetermined and selected so as to be in the most desirable places. In the Waller system, in particular, the arrangements are such that the principal stresses are assumed to be resisted entirely by the main framework which is molded on the monolithic principle, while the plates though help-

ing in resisting the shearing stresses are mainly intended to act as the skin of the vessel, being analogous to the plates of a steel ship.

It is claimed on behalf of the Waller system that a considerable saving in timber and skilled labor can be effected, because shuttering of the skin is entirely eliminated. Also, unskilled labor is economized, because the concrete of the plates is deposited at ground level, being poured quickly into open molds instead of being inserted and rammed with some difficulty between double shutters already packed with steel. It is stated that on a 1000-ton barge forty men working at once is an ample number. In a barge of 1000 tons dead-weight capacity some 200 plates are required. One plate can be cast daily on each molding bed. Therefore, if forty beds are available, the plates for the entire skin including bottom, sides and deck plates could be produced in six working days. In fact, it is believed that it will ultimately be possible to erect and concrete the hull of a 1000-ton barge in six weeks. (*Engineering*, vol. 106, no. 2760, November 22, 1918, pp. 580-583 and 586, 15 figs., *dA*)

Ship Ventilator Cowls, H. E. McCauley. Description of the processes of manufacture of ship ventilator cowls, including data on their design as used in the shops of the Sun Shipbuilding Company at Chester, Pa.

There are two types of ventilators in common use on shipboard. One has the joints crosswise on the length of the cowl between the sections that go to its make-up. This is usually called the American type of ventilator cowl. The other type of cowl is known as the European. In it the seams run lengthwise and this type is generally used for the larger sizes with mouths from 36 in. up to 84 in. in diameter or larger.

The method of laying out the templets for this type of cowl is described in the article in some detail. The article also describes and illustrates step by step the entire process of manufacture and gives an idea of the templets and forms used. (*American Machinist*, vol. 50, no. 2, January 9, 1919, pp. 47-51, 15 figs., *d*)

MEASURING INSTRUMENTS

Notes on Steam Meters, E. Claassen (*Zeits. V. reines Deutsch. Ing.* 62, pp. 521-526, Aug. 10, 1918). Though the mere provision of steam meters has a considerable indirect effect in securing steam economy, those hitherto used have conformed imperfectly to the desideratum that they should be both accurate and of rugged construction. Many types of meters yield poor accuracy, while others require skilled attention to keep them in order. Great numbers of St. John steam meters are used in America. The construction is very simple, the principle employed being that the lift of a cone opens a great or smaller steam passage according to the steam flow. In order that the lift of the cone may be directly proportional to the steam flow, the generating line of the cone's surface is made slightly curved. With a right cone, double the lift permits less than twice the flow, owing to the relatively smaller free openings; on the other hand, the increased pressure difference tends to pass more than twice the steam flow. The former factor is predominant, and to correct for it the surface of the cone is corrected by trial and error during the calibration of the meter. Calibration is therefore tedious and costly, twenty or more condensate tests often being required before sufficient accuracy can be obtained. Yet more serious is the fact that considerable errors are introduced by friction in the stuffing box through which passes the rod connecting the cone to the recording pencil. The author gives data from his own and other tests on this matter. Mere substitution of a ground spindle effects only temporary improvement if there is opportunity for scale to deposit on the metal.

One pattern of the Claassen steam meter is shown in the original article, and also the special type of packing employed. The tapered, ground-in spindle has very little friction and has proved satisfactory during 6 years' practical experience. Official test data and particulars from actual installations are given in the original. The meters are standardized by the Normal Eichungskommission (Charlottenburg). A particular meter showed the following variations from the mean constant: —2.2 per cent at 9 mm. lift; + 1.9 per cent at 43 mm. lift; and + 0.4 per cent at 58.6 mm. lift; thus the error was well within the permissible limits even at 1/7 of the maximum steam flow. A double meter used in a paper mill at Okulowka records accurately from 1000 to 11,000 kg. per hr. on one instrument, and up to 22,000 kg. per hr. when both meters are in commission.

Pressure loss in steam meters is an important factor in all except heating installations, where it is immaterial, since the energy corresponding to the pressure drop is converted into heat. The cone of the St. John meter is so heavy that it causes a pressure drop of 0.25 atmosphere, compared with 0.05 to 0.08 atmosphere in the Claassen meter. The lower the pressure drop in the meter, the more important it is to reduce friction in the packing to a minimum. The possibility of willful tampering with the packing must be borne in mind; tampering with the Claassen meter is impossible. (*Science Abstracts*, Section B—Electrical Engineering, vol. 21, pt. 11, Nov. 30, 1918 (No. 251), pp. 391-392, *g*)

MECHANICAL PROCESSES

Reversed Heads in Pressure Vessels, J. Leslie Lane. The writer questions the advisability of the use of reversed bumped head in boilers and pressure vessels generally.

The objectionable feature of such a head is that when the tank is set vertically it is next to impossible to drain it completely. Further, the dead space thus created serves as a settling chamber where oil and sediment can collect. This could be overcome only by demanding that tanks so constructed should be set horizontally.

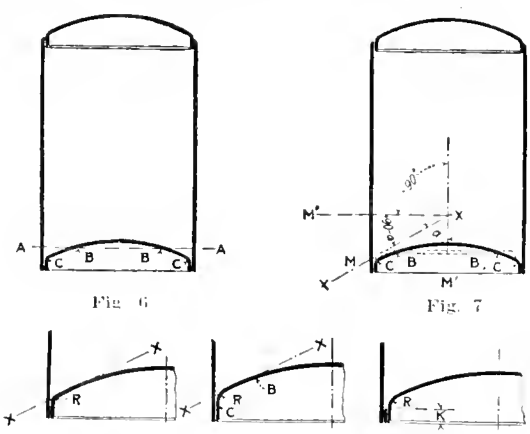

Fig. 6 Fig. 7 Fig. 8 Fig. 9 Fig. 10

Figs. 6 to 10 Diagrams Showing Action of Forces in Dished Heads

The calculation of safe pressures is a comparatively simple matter, although somewhat complicated by the presence of a bending movement at the point where the flange and the head proper join. A calculation of the capacity of a bumped head to resist collapsing pressure is more difficult, as it is somewhat analogous to buckling in bars, which latter is determined only by approximate empirical formulæ.

The writer points out that the behavior of the head under pressure depends also on the individual workmanship and the accuracy with which the head is shaped to a given radius.

If the curvature of the head is exactly the same at all points on the sphere the stresses set up in it are balanced and the flat spots needed to give the leverage for collapsing are absent. On the other hand, if there is such a leverage its action is accumulative.

Where the pressure is on the concave side such a fault tends to correct itself by forming the head to a circle; in a reversed head it tends to accentuate itself and to lead to a failure of the whole.

This makes high-grade workmanship absolutely necessary. The uncertainty as to the actual stresses present led to a stipulation that such heads shall have a minimum thickness considerably greater than would be the case if they were put in in a regular manner and the pressure applied on the concave side.

The following passage taken from the original article is of interest:

Turning to Fig. 6, observe what form the bumped head will first

assume when a distorting pressure is applied and what stresses it will develop in the shell. The problem is similar to buckling in a beam, and whatever distortion disappears will be about the neutral axis AA, no effect being noticeable at the points B where the axis cuts the head.

If the part BB is to bulge outwardly finally, it must first be flattened, the part BC of the head being distorted and assuming the shape shown in Fig. 7. This places the part BC in compression and the stress will be exerted along the tangential line XX. Without attempting to determine the exact intensity of this stress, assume it to be M pounds and resolve it into its two components, one parallel to the axis of the shell, the other at right angles to it.

Supposing that the line XX makes an angle a with the axis of the shell, then the force M' acting parallel to the axis of the drum will be $M \cos a$ and its effect will be wholly exerted on the rivets holding the head in position. The force M'' acting at right angles to the axis of the drum will be $M \cos$ (90 deg., a) and its effect will be partly exerted on stretching the metal in the part BC of the head, and in expanding the shell of the drum itself. To put the proposition in a simpler way, the action is a toggle effect, the outer rim of the head being stretched and forced out against the shell, tending to rupture it.

Just how much of this toggle effect is brought to bear on the shell of the drum depends on the radius R, where the head meets the flange. If the radius is small, as in Fig. 8, then any expansion of the head must affect the shell, for the thrust comes directly against it. On the other hand, if this radius is large, as in Fig. 9, the part BC of the head is free to spring and the stretching of the shell is minimized. This would lead to the conclusion that in reversed heads the radius at the knuckle of the flange should be considerably larger than in the case of straight dished heads of the customary type. In order to reduce still further this toggle effect, the writer believes it would be advisable to insert a filler piece between the flange of the head and the drum, as shown in Fig. 10. It need not be thick—probably one-eighth inch would be sufficient—and where possible it would be of copper. Its width K should not exceed 2½ in., in order that a clear space be left above to take care of any expansion of the head.

The writer sums up the advantages and disadvantages of the reversed head and comes to the conclusion that where safety is a necessary factor, the reversed head should not be used. (*Power*, vol. 49, no. 2, Jan. 14, 1919, pp. 61-62, 5 figs., *ptA*)

Manufacturing Marine Steam Boilers, E. A. Suverkrop, Mem.Am.Soc.M.E. Description of the processes used in the boiler shop of the Sun Shipbuilding Company, of Chester, Pa. The boilers manufactured are of the so-called Scotch type, single-ended, with three furnaces.

The article, which is profusely illustrated by photographs and line cuts, describes in general the layout of the boilers, the rolling of the shell plates to the desired curvature, the location and boring of the holes, the flanging and all subsequent operations in considerable detail.

Among other things are described in some detail the tools used by the company in the manufacture of the boilers: in particular, the rolls and the flanging press. The flanging machine also does the work of forging or upsetting the ends of the large staybolts used in these boilers.

The article is of interest in that it gives a broad view of the operations involved in the manufacture of a large marine boiler. (*American Machinist*, vol. 49, no. 26, December 26, 1918, pp. 1155-1163, 21 figs., *dA*)

MECHANICS

Hardness: Its Nature and Measurement

Hardness, James J. Guest. The paper here abstracted was presented in the form of a discussion on the paper by R. G. C. Batson entitled The Value of the Indentation Method in the Determination of Hardness, at the November 15 meeting of the Institution of Mechanical Engineers in London.

To indicate the nature of hardness the author sketched the stress-strain diagram reproduced in Fig. 11 with the curve distorted for the sake of clearness but generally typical.

In Fig. 12 is shown a tool penetrating the material. The author pointed out that the state of stress in the material would vary throughout, the states of stress at a, b, c, d, e corresponding in type to those represented at A, B, C, D, E in Fig. 11, though the stress within the material would be complex. In addition to this there would be a surface of discontinuity, as marked, through b. Outside this surface the material would possess elastic strain energy, within it there would be overstrain, involving lost energy, combined with elastic energy, and in the tool elastic energy only. The tool was supposed to be acted upon by the force P indicated.

A tool of any conical shape, as that sketched, did not involve any linear dimension, and hence in the position shown there was only a single linear dimension involved, which was the diameter d of the indent. Hence, the tool being in equilibrium under the

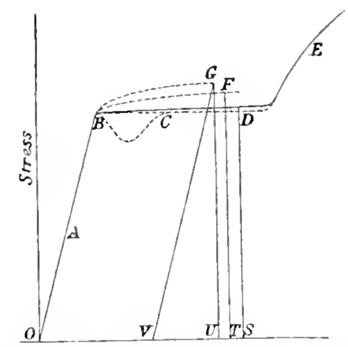

Fig. 11 Stress-Strain Diagram of Hardness Test

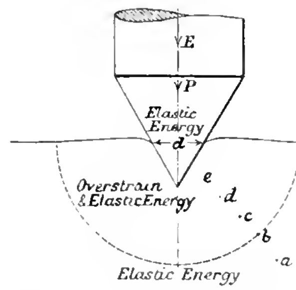

Fig. 12 Tool Penetrating Material in Hardness Test

Fig. 13 Diagram Showing Surfaces of Contact between the Tool and Material in Hardness Test with Varying Depths of Impression

force P and the reaction due to the stress condition in the material, there must be a relationship involving P, d, and certain complex stresses and elastic constants of the material, represented under the head p in the summation equation:

$$P = \Sigma A d^k p^l \ldots\ldots\ldots\ldots\ldots\ldots\ldots [1]$$

As throughout p was of the dimensions of stress, by dimensional theory the only possible values of the indices were $k = 2$ and $l = 1$, and therefore P/d^2 must be a constant for the material.

Referring again to Fig. 11, along O, A, B—the Hooke's law portion—the relationship of stress and strain was independent of time, but near and beyond B a time effect showed itself, the curve taking such forms as indicated by the broken line, the metal having a semi-viscous flow. Hence Equation [1] would not be quite true and the value of P/d^2 would not be quite independent of the time. But from the known proportions of phenomena represented typically by such curves it was clear that P/d^2 was the predominant factor in the law of indentation.

Mr. Guest then considered the case of an impact test, Fig. 12 again representing the case of a tool applied with energy E, the

corresponding summation equation for the indentation being:

$$E = \Sigma B d^m p^n \ldots\ldots\ldots\ldots\ldots\ldots\ldots [2]$$

The indices again had single values, $m = 3$ and $n^* = 1$, so that E/d^3 was necessarily a constant for the material.

The stress-strain diagram in Fig. 11 represents a slow test. The effect of a rapid application of the load is to raise a portion of the curve beyond B, as shown by the dotted curves BF, BG, and the more rapid the application of the load the higher would be the curves.

If at the point G the stress was removed, the curve fell along the line GV, the energy measured by the area $OBGV$ being destroyed, but that represented by the area GVU restored by the material. The proportion of energy reaching any element of the material varied; at points such as a in the elastic region it was practically all restored, and the proportion of energy restored gradually diminished along b, c, d, e. Except for losses—such as due to vibration—the sum of this energy (with that in the tool) appeared in the rebound energy of the hammer, so that the height to which it rebounded duly measured some complex summation determined by the elastic and stress laws of the material.

If the tool instead of being conical were of a wedge shape of indefinitely long edge, then again there would be no linear dimension involved in the tool and all the above would apply. When, however, a ball is used as a tool its diameter is involved and with varying depth of impression the similarity of the surfaces of contact between tool and material ceases, as is shown in Fig. 13. If, however, the impressions were of nearly the same magnitude, the main factor must still be of dimensions $\frac{\text{force}}{\text{length}^2}$.

The paper also contains an extensive criticism of various statements in the paper by Professor Edwards, which may be abstracted together with the original paper at a later date.

In connection with the rule that the dynamic hardness was to be measured by E/S^2, where E was the applied energy and S the spherical area of indentation, R. G. C. Batson has compared the values of the measures for the hardness obtained by dividing the applied energy by the volume of indentation V and by S^2. He plotted the quantities V and S^2 against one another, calculating them from the formulae

$$V = \frac{\pi}{3} h^2 \left(\frac{3}{2} D - h\right) \text{ and } S^2 = \pi^2 d^2 h^2$$

which he gave.

In this connection Mr. Guest calls attention to the fact that the elimination of h (depth of indentation) between these equations did not give a straight line, and the departure from straightness as represented by $\frac{2}{3}\frac{h}{D}$ is 0.067 for the data selected by Mr. Batson and 0.01 to 0.045 for the experiments with balls of various diameters made by Professor Edwards.

As regards these latter, Mr. Guest gives Table 3, in which the last two columns are added by him personally. The variation of the figures in the column E/V does not suggest dependence of the shape of the curve upon ball diameter.

TABLE 3 GUEST'S DATA ON HARDNESS TESTS

E Energy of Impact	V Volume of Indent	d Diameter of Indent	D Diameter of Ball	h Depth of Indent	S Spherical Area	C Professor Edwards' Constant	$\frac{E}{S^2}$	$\frac{E}{V}$
0.054	0.25	2.234	10.00	0.126	3.97	4.635	0.00343	0.216
0.089	0.45	2.584	10.00	0.170	5.33	4.730	0.00314	0.198
0.158	0.73	2.376	4.76	0.319	4.77	3.760	0.00697	0.217

In this connection and, in particular, in connection with the formula of J. O. Roos, Mr. Guest connected Professor Edwards' constant with the volume of indentation, writing:

$$\frac{d^4}{V} = \frac{32D}{\pi}\left(1 - \frac{h}{D}\right)^2 \left(1 - \frac{2}{3}\frac{h}{D}\right)^{-1}$$
$$= \frac{32D}{\pi}\left(1 - \frac{4}{3}\frac{h}{D} \ldots\right)$$

thus showing that C^{-4} was of the same nature as the expression of Mr. Roos, but with a different coefficient for the term h/D. That the values of C tabulated varied less than the values of E/S^2 was due to the glozing over of the effect of the variation of the diameter ratio by taking its fourth root. This, however, simultaneously reduced the whole variation of the constant and hence the gain is illusory.

As h/D was small, there was little difference between E/V, ED/S^2 and $C^{-4}D$. Now the energy summation for the ball impact might, taking h the permanent indent and D as the involved lengths, be written

$$E = rD^3 + SD^2h + tDh^2 + uh^3$$

since E increased with D and h. Putting $h = 0$, $E_0 = rD^3$ was the energy which would just not produce a permanent indent. This had some value, and as it varied with D^3 the ball method was not well adapted to make "absolute" determinations. Since, to a first approximation, $4Dh = d^2$, the above equation might be written

$$E = rD^3 + S\ 4Dd^2 + t\ 16\frac{d^4}{D}\left(1 + \frac{u}{t}\frac{h}{D}\right)$$

With a given diameter of indent a small ball penetrated further than a large one, and therefore the second term was probably zero. Hence the most important feature must be the third term. The experiment work confirmed this. The above coefficients should form the aim in experimental work.

These remarks call forth a certain amount of criticism. H. L. Heathcote said that it is the opinion of Mr. Guest that the energy of the blow was equal to the sum of certain energies on the other side, namely, the elastic energy in the denting tool and the elastic energy in the specimen plus strain energy. The speaker thought that the energy required to move the metal should also be taken into account.

When experimenting with the punch referred to in Batson's paper and applying the curve showing the relation between diameter and depression produced and the Brinell numbers, the speaker had not obtained a curve exactly parallel with the curve showing in the Brinell diameter as a function of the hardness. Both were sloping curves, with the further significant characteristic that one curve crossed the other in two places. Crossing of the curves suggested that the hardness as found with the autopunch of a hard specimen was greater and that of a soft specimen less than would be found with the Brinell test. The writer claims that the Brinell test crushed a hard specimen, disintegrating the metal, and that the impact test got its work done before the crushing and softening had taken place.

Several other interesting discussions reported in the original article cannot be abstracted because of lack of space. (*Engineering*, vol. 106, no. 2760, Nov. 22, 1918, pp. 588-591, 4 figs., *tA*)

Bureau of Standards Tests of Large Brick Piers

THE COMPRESSIVE STRENGTH OF LARGE BRICK PIERS, J. G. Bragg. The following is an abstract of the report on tests of large brick piers which were made at the Pittsburgh laboratory of the Bureau of Standards in coöperation with the National Brick Manufacturers' Association.

The purpose of this investigation was to determine the strength developed by brick piers of normal size as used in modern buildings, using in their construction such materials and grades of workmanship as are available in the United States.

The variables considered in the investigation are: (1) the quality of bricks employed with respect to grade and geographical location; (2) the quality and kind of mortar; (3) the grade of workmanship employed, and (4) the bonding of courses or method of laying the bricks.

* In the original, p is erroneously referred to here.

The investigation comprised tests on 46 piers 30 in. by 30 in. by 10 ft. in height, also 4 piers of the same cross-sectional dimensions 5 ft. in height. The bricks used in their construction are representative of four widely separated districts east of the Mississippi river and are classified according to the following 3 grades:
Grade 1, Hard-burned or best quality
Grade 2, Medium-burned or considered as common
Grade 3, Soft-burned or poorest product marketed.

Three mortars were used in the beginning and three grades of bond and workmanship were employed throughout the investigation.

The mortars used were
a 1 part cement to 3 parts sand by weight
b 1 part lime to 6 parts sand by weight
c 1 part (0.15 lime + 0.85 cement) to 3 parts sand by weight.

The different methods of bonding were as follows:
a Alternating header and stretcher courses
b Header course every 4th course
c Header course every 7th course.

Wire mesh was used in two of the 5-ft. piers to study the effect of lateral reinforcing in the horizontal joints. A more than usual number of tests of individual bricks were made in order to determine the relation of the strength of single bricks to the compressive strength of piers.

The first indication of failure observed was the same in all cases and appeared in the form of small hair-sized cracks in the individual bricks. The cracks widened and extended to other courses under additional load, finally becoming confluent and extending almost the entire length of the pier. Soon thereafter final failure occurred accompanied by a spalling off of the outer ring of bricks. Very little crushing of the bricks was apparent after failure except in the case of the softer bricks laid in cement or cement-lime mortars. The cause of incipient failure of the piers is attributed to a transverse failure of the individual bricks.

The tests show that variations in the number of header courses used does not affect the ultimate compressive strength of the pier. Failure of the individual bricks by flexure would render the header courses ineffective by such time as they would be useful in preventing an outward bulging of the masonry.

The quality of brick is shown to be a very important factor in its effect on the compressive strength of the pier. The compressive strength of half-bricks flat and on edge, also the transverse strength or moduli or rupture of the bricks, are shown to be proportional to the compressive strength of the piers.

Very little difference in strength is apparent in piers of 1:3 portland cement and sand mortar and those of 1 (15 per cent lime and 85 per cent cement): 3 sand mortar. In the last-named mortar 35 per cent by volume of the cement is replaced by lime. These piers of cement and cement-lime mortars, however, developed strengths 50 per cent to 75 per cent higher than those of pure lime mortar. There is a considerable advantage in the easier working qualities of the cement-lime mortar over the pure portland-cement mortar. In consideration of the results of these and previous tests on piers of smaller cross-sectional dimensions, from 35 per cent to 50 per cent of the cement in a 1:3 cement mortar may be replaced by hydrated lime without appreciably affecting the compressive strength of the masonry; the higher percentage to be used in piers of small cross-sectional dimensions.

A study of these and previous tests indicates that lateral reinforcing in the horizontal joints is effective only when placed in every joint.

The following empirical formulæ are given for use in computing the strength of brick piers:

$$P = Kp \quad [1] \qquad P = KR \quad [2]$$

where
P = ultimate unit compressive strength of the pier
p = unit compressive strength of single half-bricks
R = unit transverse strength or modulus of rupture of single bricks
K = a constant depending upon the kind of mortar used.

The values of K are given in Table 4 for the mortars used in this investigation.

The modulus of rupture is computed according to the formula

$$R = \frac{3}{2}\,\frac{Pl}{bD^2}$$

in which
R = modulus of rupture
P = breaking load, in pounds, of a single brick in a flatwise position supported at the ends and loaded at the center
l = distance between the supports (in these tests 7 in.)
b = breadth of specimen in inches
d = depth of specimen in inches.

TABLE 4 VALUES OF MORTARS USED IN INVESTIGATION

Mortar	Values to be determined by tests of single bricks	Value of K
1 part (0.15 lime + 0.85 cement) to 3 parts sand by weight	Unit compressive strength flat $= P$	0.26
	Unit compressive strength on edge $= p$	0.30
	Modulus of rupture from transverse test $= R$	1.25
1 part lime to 3 parts sand	Unit compressive strength flat $= P$	0.11
	Unit compressive strength on edge $= p$	0.14
	Modulus of rupture from transverse test $= R$	0.65
1 part cement to 3 parts sand	Unit compressive strength flat $= P$	0.27
	Unit compressive strength on edge $= p$	0.32
	Modulus of rupture from transverse test $= R$	1.45

The complete report includes 24 figures and numerous tables. There is also a chapter devoted to previous tests giving abstracts and tables of the results from previous investigations of the load bearing values of brick piers. (Abstract from Technologic Paper No. 111 of the Bureau of Standards; *eA*)

German Analysis of the Belt Drive

MECHANICS OF THE BELT DRIVE, Dr. Wilhelm Stiel. The original article abstracted here represents in itself an abstract of a book published by the author in 1918, in which he considers the properties and modes of operation of belt drives in general, and, in particular, the relation of forces acting during the process of power transmission by belting.

In the first place, the author considers a belt drive with extremely low velocities of translation of the belt.

The only relation between the forces acting on a belt, which must prevail under all circumstances, is the condition of equilibrium, in view of which the sum of all forces must be equal to zero. As regards external forces acting on the belt pulley (neglecting the individual properties of pulley as is done throughout this discussion), there are, in the first place, the two tangential forces S'_1 and S'_2 and the axial force A, and because of the condition of equilibrium we must always have

$$A + S'_1 + S'_2 = 0 \ldots\ldots\ldots\ldots\ldots [1]$$

with the further condition that the addition of forces, as a rule, should be carried out geometrically and that only in particular cases does an algebraical addition become permissible. If we take into consideration the general equation for the effective force

$$S_n = S'_1 - S'_2 \ldots\ldots\ldots\ldots\ldots [2]$$

then we find for the axially acting force the expression

$$A + S'_1 + S'_2 + S'_2 = 0 \ldots\ldots\ldots\ldots\ldots [3]$$

For a drive with ratio [1] we have an algebraic equation

$$A = S_n + 2S'_2 \ldots\ldots\ldots\ldots\ldots [4]$$

which has a general application provided we understand that by A is meant not the axial pressure, but the sum of the tangential forces $S'_1 + S'_2$. From this it follows that the deciding constituent of the axial pressure or the sum of tangentially acting forces is the transmitted effective force, and the prevailing tendency in the variation of the axial pressure will be an increase proportional to S_n.

A modification is introduced in this connection by the magnitude of tension on the loose side, which is mainly affected by the individual conditions of each drive, and especially by the magnitude of the initial tension.

The resultant variation of the axial pressure as a function of the useful load depends, therefore, quite materially also on whether and to what extent the arrangement of the drive is capable of maintaining the tension on the off side with the increase of load, and it appears that not only the axial pressure but the entire relation of forces acting in each belt drive is fully determined by the formula

$$S'_2 = f\,(S_n)\ldots\ldots\ldots\ldots\ldots\ldots\ldots[5]$$

which means that whenever a belt drive is investigated it is sufficient to determine the S'_2 characteristic in order to secure complete information as to the general state of that particular drive.

In the arrangement a, where there is no initial pressure, we have $S'_{2a} = 0$. Hence, in that case (Fig. 14) both the force on the tight side S'_{1a}, as well as the axial force A_a, are represented

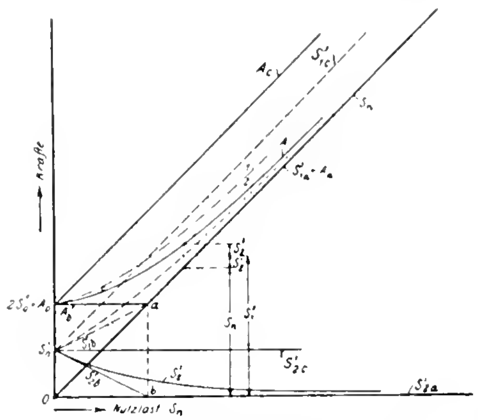

Fig. 14 Forces Acting in a Belt Transmission
Ordinates: Forces (*Kraefte*); Abscissae: Useful Loads (*Nutzlast*) S_n

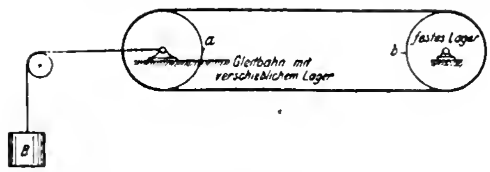

Fig. 15 Arrangement (b) of Belt Drive Giving Constant Axial Pressure
Gleitbahn mit verschieblichem Lager—Sliding support with displaceable bearing); *fester Lager*—Fixed bearing

by equal straight lines passing through the origin of coördinates, while $S'_{2a} = 0$ coincides with the axis of abscissæ. Such an arrangement satisfying the condition $S'_2 = 0$ is conceivable but difficult to execute mechanically as a belt drive. It appears, however, in all chain drives provided only we consider the chain itself as having no weight.

On the other hand, there may be an arrangement such as that devised by Bach and shown in Fig. 15, where the Grashof equation $S'_1 + S'_2 = 2S_0 =$ constant always holds good. In this arrangement, which is only of theoretical interest and can hardly have any application in practice, the axial force acts along the horizontal line A_b (Fig. 14). S'_{1b} and S'_{2b} lie along a line inclined to the horizontal at an angle arc tan ½.

Further, there may be other arrangements c in which the tension on the slack side is artificially maintained at a value different from zero, as, for example, in the Lenix drive. In such arrangements the tension on the slack side follows the horizontal straight line S'_{2c}, while the force on the tight side and the axial pressure are expressed by straight lines S'_{1c} and A_c (Fig. 14) parallel to the line of effective force.

In the usual arrangements of belt drive where the initial tension is created not by artificial devices, but exclusively by the elasticity and weight of the belt itself, the curves expressing S'_2, S'_1 and A are all located within the part of the diagram determined by the straight line corresponding to each of the arrangements a, b and c.

The writer gives some further indications as to the behavior of these curves which help to recognize their character.

First, all the curves S'_2 have as tangents at their origin S'_0 the straight line S'_{2b} having an angle of inclination arc tan ½ and asymptotically approach the axis of abscissæ.

Next, all the curves S'_1 have at their origin S'_0 as a tangent the straight line S'_{1b} rising at an angle arc tan ½ and asymptotically approach the lines of effective force S_n and S'_{1a}.

All the curves A have at their origin $A_0 = 2S'_0$ as tangent the horizontal line A_b and asymptotically approach the lines of effective force S_n and A_a.

In order to determine the actual course of the curve $S'_2 = f(S_n)$ given in equation [5], the writer applies a graphical method based essentially on the work of Kurtzbach and Barth.

The results secured in this manner are compared with those experimentally obtained by Lewis in 1886. These results are represented in the form of curves of average values (Fig. 16) and indicate a complete accord with what should be expected from Fig. 14.

These tests prove beyond doubt that the excessive axial pressures occur not only at high velocities, but also at very low velocities approaching a stationary state and even in the stationary state itself.

If it should be desired to secure an approximate expression for all of these relations one might make use of the observation to the effect that the curves of axial pressure plotted in Fig. 14 are in shape similar to hyperbolas. The curves of axial pressure have low initial tensions (such as in the order of magnitude up to $2k'_0 = 10$), are practically exactly equilateral hyperbolas and follow the equation

$$A = S_n^2 + 4\,S'^2_0$$

and since $A = S_n + 2\,S'_2$, it follows that

$$A = \sqrt{S_n^2 + 4\,S'^2_2}\ldots\ldots\ldots\ldots\ldots\ldots[7]$$

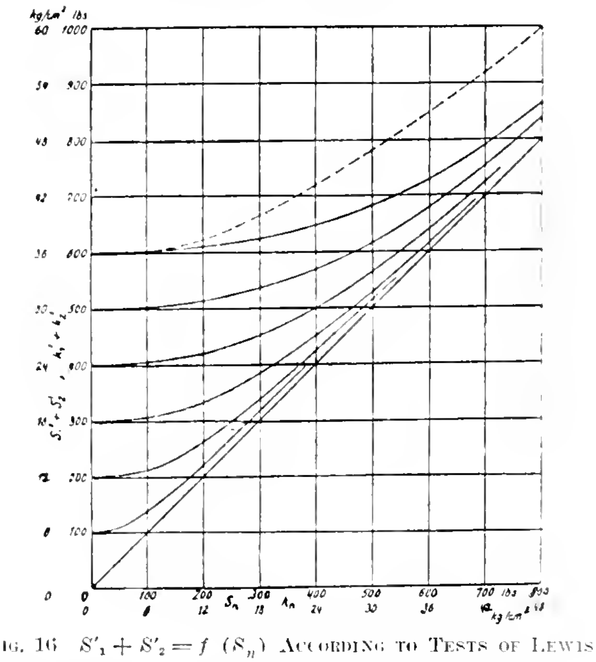

Fig. 16 $S'_1 + S'_2 = f\;(S_n)$ According to Tests of Lewis

At higher initial pressures these equations give excessively high values as may be seen from the dotted curve in Fig. 16 for $A_0 = 36$. Hence, when these curves are used they give the axial pressures correctly but are uncertain as to the way they give the variation of S'_2. The author recommends, therefore, using the hyperbolic equation [7] only for rough calculations of the axial pressure, but not for the determination of S'_2. It should also be borne in mind that equation [7] does not take into consideration the axial distance, so that it covers only normal conditions where a does not differ much from 4.

In the opinion of the author, this formula is better than the previous assumption of constant axial pressure, and the relation established by the author has, at least, the advantage of greater clearness. This relation is: The sum of the forces acting on the side of a loaded belt equals the square root of the sum of the square of the effective load and the sum of the forces acting on the side of the belt running idle. (First part of an article in *Dingler's*

polytechnisches Journal, vol. 333, no. 18, September 7, 1918, pp. 161-166, 12 figs., *p*. The second part may be abstracted in an early issue if the space is available.)

A Relation Connecting the Derivatives of Physical Quantities, Mayo Dyer Hersey. In this paper it is shown how the theory of dimensions may be used in a differential form; a procedure which appears fruitful, particularly in investigating the effect of given sources of error on the performance of measuring instruments. The examples which led to the necessity for developing this method are discussed at the end of the paper and illustrated by experimental data. (Abstract from Scientific Paper No. 331 of the Bureau of Standards; *t*)

POWER PLANTS

Generator Wreck at St. Paul. Description of the wreck of a 2000-kw. generator on December 10, 1918, in the St. Paul (Minn.) plant of the Northern States Power Company.

The trouble was caused by a workman short-circuiting a 13,000-volt feeder in Minneapolis connecting the St. Paul and Minneapolis plants. The St. Paul plant was subjected to short-circuit of such proportions and duration that the excitation (from a motor-generator set) was practically lost on the two turbo-generators then operating, and by the time another exciter was put in operation the generator end of one of the units, namely, the 2000-kw., was completely wrecked.

The steam end of the turbine remained intact, although the shaft was probably sprung and the casting supporting the turbine bearing cracked, but the generator and its bedplate were completely wrecked.

Just how the wreck occurred is not quite clear yet. One of three things may have happened:

1 The machines being subjected to this short-circuit for several minutes caused the mechanical collapse of the 2000-kw. unit.

2 The machines remained on the short-circuit until it was cleared, and the entire system, many times 3000-kw. capacity, endeavored to bring them into step.

3 The machines under this terrific short-circuit overload dropped their load, due to loss of excitation, and the 2000-kw. overspeeded until the generator exploded.

The first assumption is unlikely, as a short-circuit located at the end of a 10-mile feeder would not wreck the machine mechanically, and the latter was not burned out electrically as no smoke or blaze was noticed.

The second assumption is also unlikely, since the 1000-kw. unit was not affected. Therefore overspeeding seems to be the most probable cause. The turbines had been in service nine years, were built for 150 lb. steam pressure and no superheat, and were actually operated under 185 lb. steam pressure, 100 deg. superheat and 6 lb. back pressure. Owing to this changed steam condition, the company operating the plant had dismantled the automatic safety stop on the three type C machines, depending upon the system to lock them electrically and load changes to be handled by the regular governor operating on the primary and secondary valves. Both of these valves were opened to the maximum on the short and the machines operating at much reduced speed. When the load was dropped, owing to this loss of excitation, the generators instantly speeded up. The governor on the 1000-kw. turbine closed its valves and kept the machine at normal speed under steam. The valves of the 2000-kw. turbine did not close tight, or for some other reason the governor did not control this machine. The overspeed trip actually tripped, but as the automatic safety stop was dismantled, it was useless and the generator reached a speed where the fourteen $2\frac{1}{2}$-in. bolts per field pole were elongated and the poles struck in the stator, which twisted off the shaft and wrecked the machine. (*Power*, vol. 49, no. 2, Jan. 14, 1918, pp. 40-41, 3 figs., *d*)

RAILROAD ENGINEERING

Feedwater Heating for Locomotives

Locomotive Feedwater Heating, H. S. Vincent. Discussion of the exhaust-steam and waste-gas methods of preheating for locomotive boilers. The exhaust steam contains a greater quantity of heat than waste gases and this heat is more readily transferred to the feedwater, but only a limited amount of the steam can be diverted for heating purposes as the exhaust rate is required for helping the draft on the locomotive.

As regards waste gases, they carry off from 20 to 45 per cent of the heat in the fuel and it would seem that this great loss offers a promising field for economy. Little progress, however, has been made in this direction partly because of the slow rate of transfer

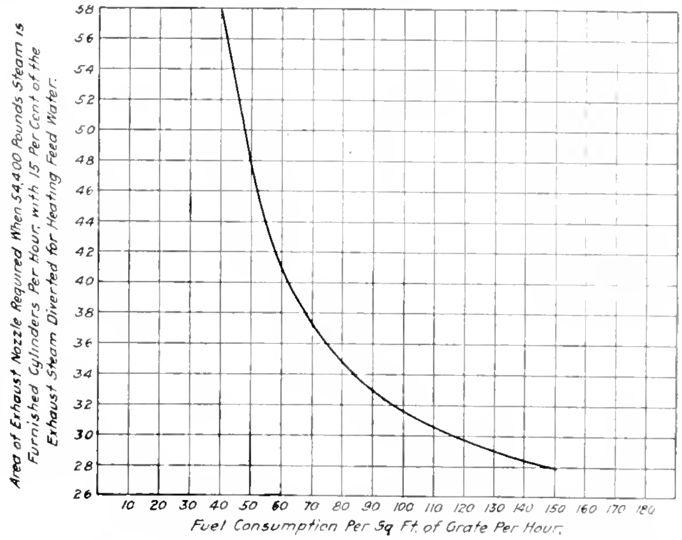

Fig. 17 Area of Nozzle in Square Inches for Various Rates of Combustion

between this heat and the feedwater and also because of other practical difficulties.

The present paper gives calculations for both types based on an equipment suitable for application to a typical high-speed passenger locomotive of which the principle dimensions and characteristics are given. The article, generally, is not well suitable for abstracting and only certain of its features will be reproduced here.

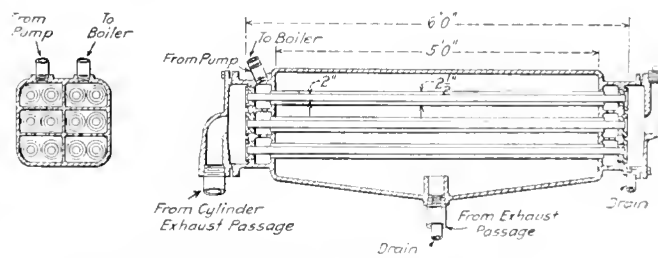

Fig. 18 A Type of Exhaust-Steam Feedwater Heater

In the first place, the author shows that the statement that a portion of the exhaust steam may be diverted for heating the feedwater without necessitating a reduction in the area of the exhaust valve, is not correct. Any decrease in the weight of steam passing through the exhaust nozzle, unless accompanied by a proportionate decrease in the amount of fuel consumed, will be detrimental, and this has been proven by extensive tests made on the locomotive above referred to.

The writer gives formulæ for determining the area of nozzle required to produce the necessary draft when diverting a predetermined proportion of the exhaust steam for such purposes as feedwater heating. Thus, in Fig. 17 are plotted the areas of nozzle in square inches for various rates of combustion, which show that these areas depend directly upon the economy given by the feedwater heater.

Fig. 18 illustrates diagrammatically the type of exhaust-steam heater in which the feedwater circulates through the annular passages between the inner and outer tubes, the heating medium flowing through the inner tube and surrounding the external surface

of the outer tube. To provide sufficient volume the pipes are arranged in pairs, six such pairs or units forming the heater. The feedwater is forced by a feed pump into the header at one end of the heater, it then flows in columns to the opposite header, traversing the entire length of the heater and flowing thence to the boiler. The heating medium (exhaust steam) is taken from any convenient point between the cylinder and the exhaust nozzle. It enters the heater at one end, flowing through the twelve internal pipes to the opposite header; exhaust steam also enters the casing and surrounds the outer pipes, the condensate being carried to any convenient point.

For a heater of the dimensions shown in Fig. 18 the total traverse of the feedwater is 30 ft. and of the exhaust steam in the inner

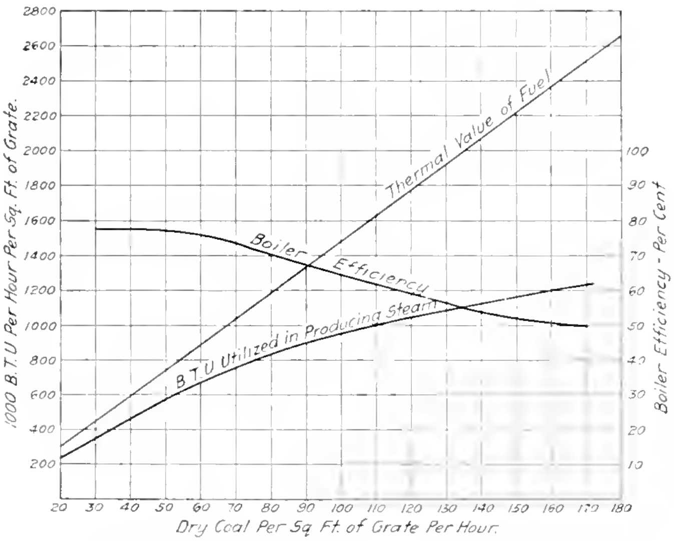

Fig. 19 Efficiency Curves of a Locomotive Boiler without a Feedwater Heater

channels, approximately 6 ft.; the total heating surface in tubes is 71.22 sq. ft. As a modern boiler-feed pump will deliver 100 lb. of water against a boiler pressure of 205 lb. for 1.75 lb. of steam, the total weight of water per hour passing through the heated is $54{,}400 \times 1.0175 = 55{,}390$ lb. or 15.35 lb. per sec.

The volume per foot of the annular space between a pair of tubes in the heater of Fig. 18 is 26.96 cu. in. and the weight of water at 60 deg. is 0.972 lb. per foot of tubes. The velocity of water passing into the heater is $15.35/0.972 = 15.75$ ft. per sec.

The pressure of the exhaust steam entering the heater is 13.7 lb. gage or 28.4 lb. absolute, the corresponding temeprature of saturated steam being 247 deg. fahr.

The writer discusses the determination of the amount of heat transmitted to the feedwater in its passage through the heater and gives a set of curves representing conductance values at different temperatures and at various feedwater velocities. Another diagram establishes the relation between the temperature of the heating medium and the total conductance at a feedwater velocity of 15.75 ft. per sec. which prevails in the case of the feedwater heater shown in Fig. 18.

As regards the economy secured with the heater, formulæ are given for determining the direct economy, which is the reduction in the number of thermal units which the boiler must supply. In addition to this, however, there is an indirect saving due to the diminished boiler losses resulting from the decreased fuel consumption and in this connection Fig. 19 is of interest, as it gives the relation between the thermal value of the fuel fired and that utilized in the production of steam; in other words, the boiler efficiency as determined from the tests of the locomotive. In this figure this boiler efficiency is plotted in relation to the unit fuel consumption per hour. In this instance for a unit fuel consumption of 120 lb. the boiler efficiency is 59 per cent and for a unit consumption of 111.5 lb. an efficiency of 61.6 per cent is secured, or an indirect economy of $61.6 - 59 = 2.6$ per cent, which added to the direct saving previously found to be 7.2 per cent gives a total economy of 9.8 per cent. This is the maximum economy obtainable with the heater in Fig. 18 when diverting 15 per cent of the exhaust steam.

The writer refers also to the feedwater heater described in a paper by George M. Basford (Mem.Am.Soc.M.E.) published in The Journal of The American Society of Mechanical Engineers for September 1917. In that heater the feedwater passes in a thin film between two spirally corrugated copper tubes. The following calculation is presented as a basis of comparison between the heater of Fig. 18 and that described by Mr. Basford.

The value of K or the conductivity of the steel tube as experimented with by Clement and Garland is 48.36 B.t.u. The value of K for copper as given in Marks' handbook is 220 B.t.u. The conductance of the steel tube is 1.204 B.t.u. Using the same thickness for the copper tube as for the steel tube experimented with, the conductance of the former is $(220 \times 1.204)/48.36 = 5.48$ B.t.u. We can combine this conductance with that of the two films as established by Clement and Garland by taking the value shown in Fig. 20 for a water velocity of 15.75 ft. per sec.

It will be observed that the curve for the conductance of the water film is approximately a straight line; while the curve for the combined conductance of tube and film drops away as the velocity of the water through the tube is increased; indicating that the conductance of the metal in the tube is not constant for all velocities.

Reading the values from the diagram, we have:

$$\frac{1}{\dfrac{1}{0.345} - \dfrac{1}{0.505}} = 1.184 \text{ B.t.u.}$$

This gives the conductance of the metal in the tube at the given velocity of the feedwater. Assuming that the conductance of the

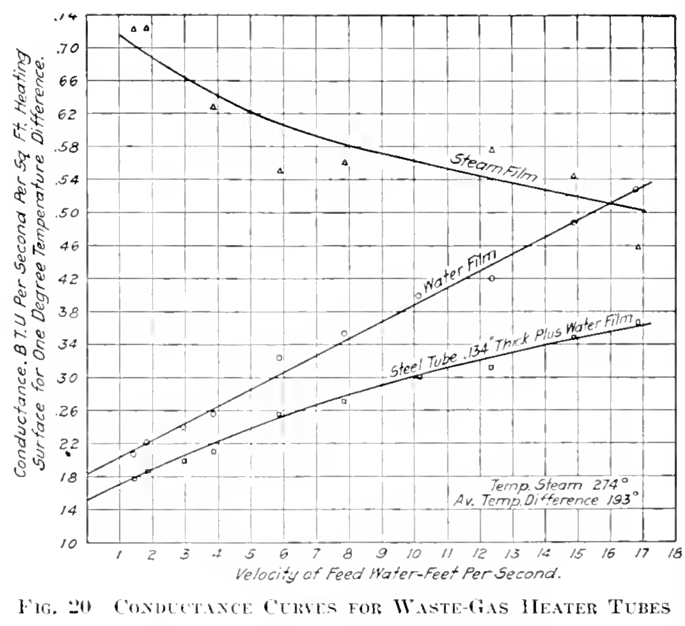

Fig. 20 Conductance Curves for Waste-Gas Heater Tubes

copper tube will decrease with the velocity in the same ratio, we have as the conductance:

$$\frac{1.184 \times 220}{48.36} = 5.39 \text{ B.t.u.}$$

Combining this conductance with that of the film, we have:

$$\frac{1}{\dfrac{1}{0.505} + \dfrac{1}{5.39} + \dfrac{1}{0.512}} = 0.234 \text{ B.t.u.}$$

The conductance in B.t.u. per sq. ft. of heating surface is then $0.234 \times 3600 = 875$, which agrees very closely with the figure given by Mr. Basford, or 900 B.t.u.

Using the latter figure, we have $900/3600 = 0.25$ B.t.u. conductance; substituting this value in equation above, we have for the heater of Fig. 18 with 30 lin. ft. traverse a final temperature of 178.05 deg. with a thermal content of 145.93 B.t.u. From the

figures given it would seem that the increased efficiency of the heater shown by Mr. Basford is due chiefly to the higher conductance of the metal used.

The foregoing abstract is from the *Railway Engineer*, vol. 92, no. 12, December 1918, pp. 645-649, 8 figs. A continuation of the article is devoted to the following discussion of feedwater heating by waste gases as the heating medium.

Because of the relatively slow absorption of the heat by water from gases, it is necessary in this type of heater to increase the heating surface quite materially over that required for an exhaust-steam heater. This is usually accomplished by employing a large number of tubes of small diameter.

Fig. 21 shows diagrammatically the heater on which the present study is based. It is composed of 320 tubes of 1 in. outside diameter, 6 ft. long, with walls 0.095 in. thick, giving a total heating surface of 407 sq. ft. The tubes are fixed at each end into headers divided into ten compartments each of which contains 32 tubes.

The feedwater enters the lower compartment of one header, flowing thence through the 32 tubes to the opposite header and in this way traversing the heater ten times before passing into the boiler.

The transmission of heat from the waste gases into the feedwater is determined by the author on the basis of the evaporative capacity of a boiler tube under similar conditions.

He finds on the basis of Bulletin 1017 published by the American Locomotive Company that the conductance of the boiler tube is 0.002325/0.523 = 0.00445 B.t.u. per sec. per sq. ft. of heating surface per degree temperature difference.

Further, with data secured by Geo. L. Fowler (Mem.Am.Soc. M.E.) the author determines the velocity of water in ft. per sec. through each pass as being 15.35/7.14 = 2.15 ft.

This is followed by an interesting discussion of the value of the resistance to heat transmission of the film on the gas side, which is of importance, because, apparently, the low heat transmission from gases to water is due mainly, if not solely, to the presence of this gas film.

Reading from Fig. 20 we find at a water velocity of 0.65 ft. per sec., a conductance through the tube and water film of 0.1635 B.t.u. per sec. The conductance of the boiler tube has been found to be 0.00445 B.t.u. As the resistance to heat transfer is the reciprocal of the conductance, we have

$$\frac{1}{\dfrac{1}{0.00445} - \dfrac{1}{0.1635}} = 0.00458 \text{ B.t.u.}$$

or the conductance of the film on the gas side.

In the Clement and Garland experiment, the thickness of the tube walls was 0.134 in., with a conductance through the metal of 1.204 B.t.u. With tubes 0.095 in. thick the conductance of the metal is $1/(6.2 \times 0.095) = 1.697$ B.t.u.

Referring again to Fig. 20, in which the conductance is plotted in relation to the velocity of the feedwater, we find, for a water velocity of 2.15 ft. per sec., a conductance of 0.227 B.t.u. Combining this with the conductance of the tube, we have

$$\frac{1}{\dfrac{1}{1.697} + \dfrac{1}{0.227}} = 0.200 \text{ B.t.u.}$$

or the total conductance of a tube 0.095 thick plus the water film. Carrying this further, knowing the conductance of the gas film, we have

$$\frac{1}{\dfrac{1}{0.200} + \dfrac{1}{0.00458}} = 0.00448 \text{ B.t.u.}$$

or the conductance of the metal, gas and water films.

In this way the total conductance is determined, which makes it possible to compute the quantity of heat transmitted to the feedwater by the heater, and when this is known it is possible to determine the economy of a given heater, which, for the heater shown in Fig. 21 is computed to be 3.4 per cent. This calculation, however, is based on two assumptions: In the first place, it has been assumed that the velocity of the gases through the heater is equal to that through the boiler tubes, and next that a feed pump is employed for forcing the water through the heater, which uses 1.75 per cent of the total amount of steam generated.

The direct economy obtained by feedwater heating with waste gases reduces the unit fuel consumption to 116 lb. and from Fig. 19 it will be seen that the ordinate for a unit fuel consumption of 116 lb. plus the boiler-efficiency curve is 60 per cent, whereas the efficiency at 120 lb. is 50 per cent. Hence the indirect economy equals 1 per cent of the total economy for the waste-gas heater 4.4 per cent.

A further economy may be secured by arranging the heaters in series with the exhaust steam as the primary heating medium and the waste gases as the secondary heating medium, the latter being possible because of the relatively great difference in the temperature of the exhaust steam and smokebox gases. The temperature of the feedwater issuing from an exhaust heater having 30 lineal ft. traverse is 163.3 deg. with the total thermal content of 131.16 B.t.u., as has been previously determined by the author. If this water, after leaving the exhaust-steam heater, be made to traverse the waste-gas heater it will attain a final temperature of 213.65 deg. with the thermal content of 181.65 B.t.u. This increase of temperature is shown by a curve in the original article. With the degree in temperature head between the waste gases and the feedwater this curve approximates a straight line.

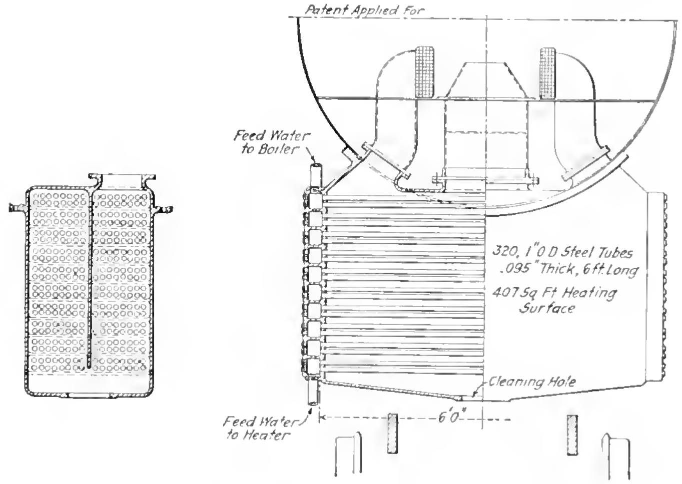

Fig. 21 Waste-Gas Feedwater Heater

The writer shows that the direct economy by series heating is 11.5 per cent, and the unit fuel consumption is reduced to 106.5 lb. to which corresponds a boiler efficiency of 62.7 per cent or an indirect saving of 3.4 per cent as shown in the diagram of Fig. 19, which, added to the direct economy, gives a total economy of 15.2 per cent.

The following conclusions are given by the writer:

Exhaust steam is superior to waste gases as a heating medium due to the low resistance of the steam film to the transmission of heat.

In a heater using exhaust steam the use of copper tubes is to be preferred to steel or iron on account of their higher conductance. Tubes should have walls as thin as is consistent with strength and wearing qualities.

Exhaust steam may be diverted for heating the feedwater without detriment to the operation of the locomotive if the area of the exhaust nozzle is decreased to give the required draft. This can be done without any increase in back pressure on the pistons.

An exhaust-steam heater such as is shown in Fig. 19, if fitted with copper tubes, will give an economy in fuel of about 11.8 per cent when using 13 per cent of the exhaust steam.

The economy of the heater using waste gases as a heating medium increases nearly in direct proportion to the heating surface. It is very difficult, however, to find space on a locomotive for a heater giving over 5 per cent economy.

High economy may be obtained by using exhaust steam and waste gases in series, but there is not sufficient room on a modern locomotive for such an application.

It is very desirable that further investigation be made of the heat-transmitting property of the gas film.

A summary of the results obtained for various types of heaters as compared with a locomotive not equipped with any but fitted with the ordinary injector is given in Table 5.

In this connection, attention is called to the fact that with the injector while the water enters the boiler at practically the same temperature as with an exhaust steam heater having 30 lineal ft. traverse, there is in the first place (injector) no economic gain, since the heat given up by the steam is equal to the heat given to the feedwater plus the external work done, which really means a loss of approximately 0.7 per cent. (Abstract made by special courtesy of the editors from an advance copy which will appear in the *Railway Mechanical Engineer*, vol. 93, no. 1, January 1919, pp. 44-47, 5 figs., *eA*)

TABLE 5 COMPARATIVE DATA OF LOCOMOTIVE BOILER PERFORMANCE WITH AND WITHOUT FEEDWATER HEATERS

	Without heater	Exhaust-steam heater		Waste-gas heater	Series heaters, waste gas and exhaust steam	
		30 lin. ft.	60 lin. ft.	60 lin. ft.	30 lin. ft.	60 lin. ft.

British View of Standardization of Railroad Equipment

Standardization of Railway Equipment. A report of great importance made by the Advisory Council of the Ministry of Reconstruction to the Minister of Reconstruction. It is based on evidence presented to the Advisory Committee by a number of experts and engineers of various companies, as well as memoranda submitted by the British Engineering Standards Association and the Locomotive Manufacturers' Association.

The report recognizes the advantages of standardization of railway equipment where it is possible, as, for example, in India, but claims that conditions in Great Britain are not suitable to its adoption because of the difference in structural and clearing gages and in tunnel dimensions.

In the existing state of things any locomotive designed to run on all the various lines would have to be a compromise and would not be the best possible for each particular railway system. However, so far as the main trunk lines are concerned, the committee is informed that a reasonably efficient engine could generally be designed for use on most of them.

The railway companies have recognized the fact that the development of the design has now reached the stage which allows of standard types being adopted when the conditions on the road are similar and have already begun to introduce standardization in so far as each company is concerned. Thus, the Committee on Locomotive Standardization set up by the Association of Railway Locomotive Engineers have now fixed on two standard engines, with the intention later to design two engines of each type, one heavy and one light, with many of the parts common to all four.

The railway companies, however, in view of the lack of material deprecate the immediate introduction of new types of standard locomotives for which new jigs, patterns and templets are required.

The report points out, however, the existence on British railways of quite unnecessary multiplication of types in certain lines. Thus the evidence before the committee showed that there are 200 different types of axle boxes and that every railroad company had adopted different types of tires, springs and axles. In fact, British railways appear to be severely handicapped by excessive freedom in the adoption of individual fitments, with the result that the working of the railroads is not as economical as it might be.

The report calls attention to the fact that British railways tend to manufacture an unusually large percentage of their supplies, including locomotives, and it is considered necessary from a business point of view to have the cost of production in the railway workshops thoroughly investigated by a competent and independent audit.

The committee also calls attention to the amount of dead weight carried on British railways. The tare of an 8-ton car built to the clearing-house regulations is 70 per cent of the load, as against the 40 to 45 per cent of the other countries.

The following recommendations are also made:

"1 That the standardization of wheels, axles, wheel centers, tires, running gear, draw gear, buffing gear, bogies, brakes and underframes be dealt with immediately by the Engineering Standards Committee, on which all interested, including private builders and makers of materials, should be represented, and that when such essential parts have been standardized the adoption of the standards should be gradually enforced.

"In view of the difficulties of standardizing complete locomotives and other rolling stock under existing circumstances, and of the excessive amount of dead weight now carried on British railways, we recommend:

"2 That a committee be formed to investigate the existing conditions of structural gages and clearances of the British railways, and the loading and unloading arrangements at works and ports, in order to ascertain how far uniformity could be introduced and tares reduced, and at what cost.

"3 That the costs of construction of locomotives and rolling stock by the railway workshops and by private firms respectively be investigated and ascertained by competent independent accountants appointed by the Government.

"In view of the great demand for rolling stock that there will be at the close of the war in this country and elsewhere, we feel that, in order to expedite delivery and to secure production at the lowest possible cost, standardization is very necessary for the export trade. We recommend, therefore:

"4 That the consulting engineers and representatives of railways financed by British capital in foreign parts in the Dominions be brought together to confer with the locomotive and wagon manufacturers in this country to determine what standardization can be effected, and that, with a view to the possibility of effecting partial international standardization, the separate Committees should take cognizance of each other's investigations." (*The Railway Gazette*, vol. 29, no. 21, November 22, 1918, pp. 548-549, *gA*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

The Secretary's Letter

PRESIDENT COOLEY'S first address to the members was at Detroit on Saturday night, January 11, on The Unoccupied Rung in the Engineer's Ladder of Fame. Dean Cooley says he spent an entire forenoon on that title! It is needless to say the address was fascinating and "gripped" every one. It was the good fortune of Prof. A. M. Greene, Jr., Chairman of the Research Committee, and the Secretary to be present at that meeting. The two latter were making a short trip to the Sections, visiting Philadelphia, Columbus, Cleveland, Chicago and Indianapolis, to take to the members the account of the work of the Society in research, publications, library, The Engineering Index, and local sections, and in turn to learn what thoughts the members have on these activities.

Notwithstanding that the Society has a large membership, the Secretary hopes he will never fail to give personal attention to the individual member and assist him in his work. The member can always be assured that the Secretary is never "too busy" to see him and never considers a request as undeserving of his personal attention. The Secretary may be engaged at the time a member calls, or away, but in such cases the other members of the staff are equally anxious to serve and, in many cases, are more familiar with the details of the member's particular request.

The spirit of the times is forcing the whole profession to a higher sense of service, consequently the Secretary is getting inspiration from the trip.

Inquiries are made of important leaders in every city as to industrial conditions, and I am happy to report a general optimism. The best-informed men interrogated believed that such depression as we might have would be short-lived and that the cycle from the present conditions down through the depression and on to the upgrade of confidence and return of industrial activity would be completed within the year.

In one of our largest industrial centers plans are already developed for large additions to be put in as soon as weather conditions permit.

Whereas labor is now plentiful and business is what would be called dull, nevertheless there seems to be little idleness and wages are being very gradually reduced. In fact, it would seem to be necessary that all prices have got to come down before much construction can be undertaken. Also the future of the railroads has got to be determined before orders for necessary extensions can be placed.

In Detroit, preliminary but nevertheless quite complete skeleton plans for the Spring Meeting were developed and members are therefore urged to save the date, June 17 to 20, as they will be rewarded with extraordinary opportunities to see the most wonderful industrial plants in the world, as well as to participate in profitable professional sessions and delightful social reunions.

CALVIN W. RICE,
Secretary.

President Cooley's Principles in Making Committee Appointments

PRESIDENT COOLEY spent ten days at the headquarters of the Society in making up his committee appointments, conferring with the Executive Committee and with a number of members who served on committees last year to get their suggestions. The following are the President's own statements of the ideas which were uppermost in his mind in his selection of committeemen:

"In view of the large membership of the Society, I think we can well establish the policy that in general, a man shall serve on only one committee, especially if it is an important and active committee and one which makes considerable demands on his time.

"In an organization such as ours, with members distributed all over the country, it ought to be possible to plan appointments so that members of certain of the committees shall all be within convenient reaching distance of some center, not necessarily New York. For example, a committee might be selected from men who are within easy distance of Chicago and the committee could hold most of its meetings in Chicago. Another committee might center around Boston, another around St. Louis, etc.

"The Society has a large number of committees. Some of these are very active; and some, because of the war or for other reasons, are doing very little. Special war committees, in most cases, can soon be discharged; and committees inactive for other reasons than the war should either be recast or discharged. Thus the number can be kept down and the time of members and also the expense be saved.

"I would like to see more of the younger members of the Society serving on committees. The honor means much to them, and they are usually keen for the work. It is not always convenient for the older men with established businesses to find the necessary time for committee work. Their experience, however, is just what is needed, and they are perfectly splendid in the sacrifices they are willing to make in order to serve the Society.

"Offers from members to serve on committees, or suggestions from members of good committeemen, will at all times be welcomed. A list of available men from which to make selections would be a great help.

"I would also welcome suggestions for changes in the organization of committees. We should be constantly on the lookout for means to improve the work of the Society. Committeemen should not be overburdened. While this cannot always be avoided, the loads can frequently be redistributed by readjustment of the committee organization.

"It will be a great pleasure if I can help in some effective way to keep the government of the Society abreast of the activities of the times. The new Committee on Aims and Organization is making an examination of these activities in the light of present-day developments, and I am sure that as their program unfolds many good sugestions will be forthcoming.

"The responsibilities of the Society increase with its growth, and to meet them the government of the Society must be ever alert and responsive. We must be prompt to adopt new measures when they appear promising, and should not hesitate to discard the old ones when they have become obsolete."

The Cleveland Plan of Engineering Coöperation

LAST WEEK the Council of The American Society of Mechanical Engineers took favorable action upon a procedure of far-reaching importance. In effect, the purpose of the Council is to practically carry forward what has long been well nigh if not indeed a wholly universal desire among technical men for the greater unity of the entire engineering profession. While the present cautious step does not go as far as some enthusiasts may desire, it is nevertheless a decided move in the right direction.

The Council by unanimous vote recorded its willingness to enter an arrangement with the Cleveland Engineering Society whereby joint membership of mechanical engineers, duly qualified according to the respective requirements of the societies, could be effectively fostered between the two organizations. There would be a division of the dues between the two societies, a reduction of $5 being made in the total amount now paid by the active or associate member belonging to both bodies. This sum, though not large enough to be deemed a serious crippling of the receipts when first applied, would, it is confidently believed, be sufficiently attractive to bring into both societies many mechanical engineers who are at present members of but one or perhaps neither of the two bodies.

The plan further contemplates that members of The American Society of Mechanical Engineers may join the Cleveland Engineering Society without the payment of an entrance fee. On the other hand, those who are already members of the Cleveland Engineering Society may join The American Society of Mechanical Engineers—after application and election in the usual and well-known way—by payment of the difference between the entrance fee of the Cleveland Engineering Society and the initiation fee of The American Society of Mechanical Engineers for the particular grade of membership sought. Mechanical engineers not members of either society but applying for joint membership will pay an entrance or initiation fee of $25; $18 of this going to The American Society of Mechanical Engineers and $7 to the Cleveland Engineering Society. Briefly, the foregoing is the tentative proposition adopted in principle by the governing boards of both societies and each is pledged to put it into experimental operation at the earliest practicable date.

For several reasons the plan could not well be given a more auspicious test. Prominent officials of the national societies, and particularly those of The American Society of Mechanical Engineers, have heartily approved of the engineer's being an active force in public affairs, that all technically trained men should unitedly serve the respective communities where they reside, as well as take an earnest helpful interest in national problems. Coöperating as engineers, no matter whether their specialties are mechanical or electrical or civil or mining or metallurgical or of any other field of technical enterprise, they should, as it has often been urged, repay in public service whatever is possible of their educational obligations.

Cleveland offers an excellent opportunity to test out the idea in a very definite and distinctive style. There the local engineering society is very strong in numbers, something over 1200. It maintains all the facilities of a club, is open every weekday, has regular and frequent meetings for all branches of the engineering professions, keeps a critical eye upon all local transactions of consequence to engineers and energetically works in team style with the Cleveland Chamber of Commerce and with other leading civic forces.

One naturally assumes that such a plan may easily lead to other and similar arrangements between national as well as local engineering societies. Certainly the expense in fees and dues does prevent many a young engineer from receiving the benefits of membership in several societies, no matter how well he may be qualified in all other respects. There is also the additional prospect that this plan evolved by the Cleveland engineers may do much toward the institution of similar local bodies elsewhere, and these operating under the above plan with one or more of the national societies of engineers. So promising is the project that we hope for it an abundant measure of success.

R. I. C.

Progress of the Screw Thread Commission

THE Screw Thread Commission, which was appointed by the Secretary of Commerce on September 21, 1919, for a period of six months, is gradually bringing its work to a close. The purpose of the Commission as defined in Section 2 of the Act of Congress which led to the Commission's appointment is "to ascertain and establish standards for screw threads." Necessarily, such an important matter presents problems which must be viewed in an extremely broad manner and originates questions involving alike the user, the manufacturers, the tool and gage maker, those engaged in international and export trade; and to a limited extent the distributor of screw-thread products.

The members of the Commission have considered themselves judiciary in their position and have endeavored impartially to secure the best information possible from all classes of people; from those skilled in the manufacture of screw threads and who have accumulated experience; those experienced in the handling and use of manufactured products; those interested from the academic point, and especially those interested in measurements relating to specifications. These elements are always present and the Commission has endeavored to obtain the best information possible from engineers and manufacturers of these various classes.

The first step in collecting information was to formulate a series of questions thoroughly covering the subject and for this purpose the Commission held three committee meetings in September 1918, two committee meetings and two public meetings for the purpose of hearing testimony during October 1918, six committee meetings and three public meetings for the purpose of hearing testimony during November 1918, and four committee meetings during December 1918. During January 1918 eleven committee meetings were held. On January 20 and 21 the sub-committees on pitches, classification, gaging and terminology prepared their final reports. On the following day the Commission was addressed by F. G. Echols, Chairman, Tap and Die Manufacturers' Association, on Tap Tolerances. The reports of the sub-committees were submitted to the Commission as a whole and adopted by it. The Commission decided that these reports should be correlated and combined into one final report and then submitted to its members. Final reports are to be considered at a meeting of the Commission on February 17 and then made public.

Over 500 communications have been received from manufacturers and engineers who are interested in screw-thread standardization. The Commission, during the taking of testimony in the different cities, was much impressed by the frankness and interest displayed by all concerned, and by the facilities offered for obtaining information. The Commission has accumulated a large amount of information on practice relating to screw bolts of various forms of thread, on machine screws, on threads for hose couplings, brass tubing, and on pipe threads. In addition to this, it has been called upon to decide upon the classification to be provided for and the terminology; questions as to the basis for fit of screw and nut; and tolerances for various forms of fit. A great deal of interest is involved in these questions, in view of the important considerations which arise in relation to the interchangeability of one part with another.

The Commission having heard testimony and collected data covering these matters, is now considering its recommendations which it is hoped to make public early in February; and the public meeting which is to be called is for the purpose of finding whether these recommendations meet the requirements of the industry.

John Fritz Medal Awarded to General Goethals

The John Fritz Medal Board of Award Committee composed of representatives of the Societies of Civil, Mining, Mechanical and Electrical Engineers, held their annual meeting for 1919 at the Engineers' Club, New York, Friday evening, January 17, and awarded their gold medal to Major-General George W. Goethals, the builder of the Panama Canal.

The medal has previously been awarded to John Fritz, of Beth-

lehem, Pa., Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas A. Edison, Charles T. Porter, Alfred Noble, Sir William Henry White, Robert W. Hunt, John Edson Sweet, James Douglas, Elihu Thomson, Henry M. Howe and J. Waldo Smith.

Colonel John J. Carty, now in France, has been chairman of the Board, but in his absence Ambrose Swasey, of Cleveland, presided. George H. Pegram has been elected chairman for 1919, and W. F. M. Goss, treasurer, in place of Prof. F. R. Hutton, who died during the year.

A Word About Conditions in England and France

Dear Mr. Rice:

The undersigned, together with Mr. H. L. Aldrich and Mr. A. J. Baldwin, members of the Society on the Technical Editors' trip abroad, constitute what may be called a committee without portfolio, appointed by President Main, to ascertain, if possible, something concerning the flow of engineers from peace-time pursuits into war activities in both England and France, and also to learn what steps had been taken for the return flow of engineers on the cessation of hostilities. Its appointment came in late October as the three of us were leaving the country as guests of the British Government through invitation of the British Ministry of Information to secure facts at first hand of conditions in the British Isles and at the battlefields.

Writing for myself, at least, I will say that the circumstances did not allow for collecting much informing data. As guests our time was very fully occupied in luncheons and dinners and in some plant visitations, with meeting captains of industry and soldiers and public men. We arrived in England only three days before the signing of the armistice, and naturally for the few weeks following the transition from war activities to normal activities was as indefinable as those in this country apparently were.

Volumes of literature had been published during the period of the war, largely under government auspices, looking to covering the problems of readjustment of industry, demobilization and reconstruction, but when the end of fighting actually came, it was clear that no formulæ had been so well perfected that the political or industrial machinery could immediately reverse itself. As we realize, even at this moment, the entire world, neutral as well as warring nations, has not yet recovered from the shock incident to the collapse of the Central Powers.

Just as our own engineering societies were appealed to by governmental agencies for assistance in developing war organizations, so were the officers of the corresponding organizations abroad asked to make nominations and to assist in attracting men to war work, but just as for a time was the case in this country, these war organizations had to be built up with such unprecedented speed that all possible sources of recruiting of engineering talent had to be engaged, and the engineering societies ceased early to be the main, or at least the sole, source of supply.

Very truly yours,

W. W. Macon.

Annual Report of Library Board

The Library Board of the Engineering Societies Library, which collection embraces the libraries of The American Society of Civil Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Institute of Mining Engineers, and is maintained as the joint library of the United Engineering Society, has just issued its annual report for 1918.

The Board for 1918 consisted of:

Edward D. Adams	Richard Khuen, Jr.
B. A. Behrend	Walter M. McFarland
William N. Best	Calvin W. Rice
Harrison W. Craver	Lewis D. Rights
Alfred D. Flinn	Samuel Sheldon
Alex. C. Humphreys	W. J. Slichter
Andrew M. Hunt	Jesse M. Smith
Charles Warren Hunt	E. Gybbon Spilsbury
F. L. Hutchinson	George C. Stone
John H. Janeway	Bradley Stoughton

Samuel T. Wagner

The total number of visitors during the year was 15,063, an average of 50 daily. In addition to this, over 1500 inquiries were received over the telephone and over 900 letters asking for information were answered.

The total number of searches made was 508. Work was done for almost every technical bureau of the Government, for the Naval Consulting Board, the National Research Council, for many firms manufacturing material and supplies for the Government, and for many of the Allied nations and their representatives.

Seventy-eight translations were made, as against 59 for 1917. Orders for photographic copies, 1150 in number, called for 6306 prints. In 1917, 791 orders for 1342 prints were received. This increase is partly due to wider knowledge of the Library's ability to supply copies in this way, and partly to the indexes in the monthly publications of three Founder Societies, which create a demand for copies of the articles indexed.

During the latter half of the year the Service Bureau of the Library has compiled a monthly index to mining and metallurgical literature, for the American Institute of Mining Engineers. This index the Institute publishes in its Bulletin.

The total number of accessions during the year amounted to 16,921, making the collection total, on December 31, 1918, 157,795 volumes and pamphlets, there being 38,975 of the latter.

A number of unavoidable causes have made it impossible to catalog all the accessions of the year, but the books of greatest importance and those most in demand have been given the preference, and have all been cared for. The remainder of the available time has been spent in revising those portions of the catalog which gave most trouble in daily use.

The number of volumes obtained as gifts during 1918 was unexpectedly large. The largest single gift, comprising about 8000 volumes and pamphlets, was a library of electrical literature presented jointly by the Westinghouse Electric & Manufacturing Company and the General Electric Company. This library, formerly the property of the joint Board of Patent Control established by these companies, includes sets of the most important electrical journals, a comprehensive collection of patents relating to electric power and transmission, and a unique series of records of adjudicated patent cases in that field.

Most of the new books issued by American publishers are received by the Library for review purposes, so that purchases of current volumes have been confined for the greater part to works published abroad.

The Library has also been the frequent recipient of gifts from many individuals and firms. Among the more noteworthy of these gifts are a collection of 370 pieces presented by Mr. Jesse M. Smith, containing interesting data on various patent litigations, and a collection of books on gas engineering, presented to the American Gas Institute by Dr. William Paul Gerhard, and transferred to the Library by that society, with his approval. Mr. Clemens Herschel presented a collection of bound pamphlets and papers published by him at various times, forming with those already in the Library, practically a complete collection of his contributions to engineering.

Three Founder Societies are now publishing indexes, viz.: The American Society of Civil Engineers, the American Institute of Mining Engineers and The American Society of Mechanical Engineers. The first and last of these are compiled by the respective societies, the remaining one by the Service Bureau. A committee is now considering the possibility of consolidating the preparation of two or more of these, under the direction of the Library. Such a consolidation of effort would permit the field to be covered more carefully without increased expense, would tend to standardize the methods used and would form an important step toward the realization of a complete, permanently established index.

Council Notes

A MEETING of the Council was held in the rooms of the Society on Friday, January 17, 1919. There were present: M. E. Cooley, *President*, in the chair, H. B. Sargent, F. O. Wells, Spencer Miller, F. R. Low, R. H. Fernald, C. L. Newcomb, John A. Stevens, Chas. Russ Richards, D. Robert Yarnall, John Hunter, Ira N. Hollis, John A. Brashear, Ambrose Swasey, Wm. H. Wiley, *Treasurer*, Geo. A. Orrok, *Chairman Publication Committee*, S. D. Collett, *Chairman Membership Committee*, W. E. Symons, *Chairman Finance Committee*, Calvin W. Rice, *Secretary*, and, by invitation, E. S. Carman, R. I. Clegg and J. H. Herron, of the Cleveland Local Section.

Special Orders

Joint Membership. Messrs. Carman, Clegg and Herron, members of the Cleveland Local Section, presented a proposed plan of joint membership in the Cleveland Engineering Society and this Society, with combination initiation fees and dues. After discussion in which practically all the members present participated, the following resolutions were passed:

Be It Resolved: That the Council of The American Society of Mechanical Engineers approve in principle the coöperative plan of affiliation of the Cleveland Local Section with the Cleveland Engineering Society as presented to the Council January 17, 1919, by the three Am. Soc. M. E. delegates from Cleveland, invited by the December Council.

Be It Further Resolved: That the matter be referred to the Committee on Local Sections and that this Committee be directed to prepare and propose an amendment to the Committee on Constitution and By-Laws for the general plan for such affiliation to all sections.

Be It Further Resolved: That the Committee on Local Sections be granted a special appropriation for one year's trial of the proposed plan, if in the opinion of the legal counsel of the Society such action can be taken without violating the Constitution and By-Laws of the Society.

Executive Committee

The President announced the constitution of the Executive Committee as follows: M. E. Cooley, *President, Chairman ex officio*, Chas. T. Main, Ira N. Hollis, John Hunter, D. S. Jacobus, Henry B. Sargent.

Standing Committees of Administration

Finance Committee. The President announced the appointment of Alexander Dow to serve for five years and reported the election of W. E. Symons as *Chairman* of the Committee.

Meetings and Program Committee. The date of the Spring Meeting in Detroit was approved. The meeting will be held June 17-20, 1919.

Wm. A. Viall, *Chairman*, F. H. Colvin, A. J. Gifford, J. N. Heald were approved on the Sub-Committee on Machine Shop Practice.

Publication and Papers Committee. The President announced the reappointment of Geo. A. Orrok.

Membership Committee. The President announced the reappointment of Hosea Webster.

Constitution and By-Laws Committee. The President announced the reappointment of James E. Sague.

Local Sections Committee. The President announced the appointment of Sumner B. Ely.

Mr. Yarnall presented a petition from the members of the Society in Washington, D. C., for the formation of a Local Section, which was approved.

The Secretary gave an oral report of his visit to the mid-western Sections during the month of January, on which he had been accompanied by Prof. A. M. Greene, Jr., *Chairman* of the Research Committee, who had presented the plans of the Research Committee.

Standing Committees

Library Committee. The President announced the reappointment of Jesse M. Smith. The annual report of the Library Board of the United Engineering Societies was received.

Research Committee. The President announced the reappointment of R. J. S. Pigott.

Standardization Committee. The President announced the appointment of W. S. Twining.

Professional Committees

Boiler Code Committee. Interpretations covering cases Nos. 205-207 of the Boiler Code were approved.

Special Committees

Industrial Relations. The President announced the appointment of the following Committee on Industrial Relations to give preliminary study to

a The advisability of establishing a permanent committee on relations between employer and employee;

b The best method of encouraging our membership to fulfill their high duty in that field for which their training and activities should fit them:

A. W. Burchard, *Chairman*

J. W. Lieb	H. D. Sharpe
M. W. Alexander	Chas. Cheney
Frank A. Scott	W. H. Manss

Student Branches. The President announced the appointment of Ira N. Hollis as *Acting Chairman*.

Appointments by the President

Tellers of Election. J. H. Lawrence, *Chairman*, Mancius Hutton, R. K. MacMaster.

American Association for the Advancement of Science. John A. Brashear and W. B. Gregory.

Engineering Institute of Canada. Annual meeting in February of the Engineering Institute of Canada, Dr. Ira N. Hollis, Past-President.

Washington Award, Western Society of Engineers. Chas. F. Brush.

Welding Committee, U. S. Shipping Board. F. L. Fairbanks. The report from Mr. Fairbanks recommending that the Society be represented in the new association of this committee to continue its work in research, was received.

U. S. Bureau of Standards. Wm. A. Viall, J. W. Upp and C. M. Hansen, as Honorary Vice-Presidents to represent the Society at a recent conference called in Washington on the subject of standardization of industrial safety codes.

Appointments by Council

Engineering Foundation. The term of service of W. F. M. Goss was changed to three years to comply with the by-laws of the United Engineering Society.

National Rivers and Harbors Congress. Wm. H. Wiley, Honorary Vice-President to represent the Society at the National Rivers and Harbors Congress, Washington, D. C., February 5 to 7.

Adjournment was taken to meet Friday, February 21, at a place and hour to be determined by the President.

Calvin W. Rice,
Secretary.

An elaborate report has been issued by the Board of Public Works of Detroit, Mich., on the proposed bridge to connect Belle Isle, the beautiful park and playground of Detroit, with the city to facilitate transportation to and from Belle Isle. This report contains many diagrams and illustrations. It was prepared by a consulting board appointed for the purpose, of which M. E. Cooley, President of the Society for the current year, is chairman.

Government Action on Recommendations of Committee on Standardization of Gages

THE following letter received by the Chairman of the Society's Committee on Standardization of Gages from the Director of the Bureau of Standards sets forth in interesting detail the extent to which the recommendations of the committee have been carried out by the different departments of the Government in coöperation with the Bureau, particulars of the amount of work accomplished, and opinions regarding the prospect of a continuation of the Bureau's activities in this direction which would be of great benefit to American industry during the reconstruction period and the ensuing peace conditions. A full statement of the work of this Committee and its recommendations to the Government departments appeared in THE JOURNAL of January 1918, on page 70.

DEAR SIR:

I have to reply herewith to your letter of December 28 requesting answers to six questions concerning the outcome of the recommendations of the Committee on Gages and Standards of The American Society of Mechanical Engineers.

The answers to your question are given below:

1 *How far have the recommendations been carried out by different Government Departments in coöperation with the Bureau of Standards?*

In reply to question No. 1, we have to advise as follows:

a The Ordnance Department has submitted practically all their master gages and also a considerable number of inspection gages for test at the Bureau of Standards in Washington. The Ordnance Department has further coöperated with the Bureau of Standards in making it a central point for the storage and dispatch of master gages. With this arrangement the shipment of gages to Army Inspectors of Ordnance at manufacturing plants having Government munitions contracts, has been greatly facilitated. In addition there has been organized at the Bureau of Standards a gage shop for the salvage and manufacture of master gages and inspection gages needed for exigency purposes. Up to the signing of the armistice this Gage Shop employed from 60 to 75 toolmakers and the equipment available included a complete tool shop equipment, such as precision lathes, grinding machinery for plain gages, thread grinders, and other shop accessories. In all about 60 machine tools were in use in this shop. With gages stored and with a salvage shop available at the Bureau, it was possible to supply sets of master gages revised to the latest component drawings, where otherwise it would have been necessary to send out gages which had become obsolete during the course of their manufacture. This Gage Shop was also used to very good advantage in the way of supplying inspection gages needed to prevent stoppage of production. Gages for this class of work were manufactured in anywhere from 3 days' to 2 weeks' time, whereas it would have taken several months to secure the gages in the ordinary procedure of securing bids and placing a formal order with gage manufacturers. An instance is mentioned in which this Bureau supplied 6 gages required for immediate use overseas within 4 days, whereas the best delivery obtainable from any Government arsenal or gage manufacturer was 2 weeks. The gages in question were immediately dispatched overseas by carrier.

The Gage Shop at the Bureau of Standards has also supplied various arsenals and district offices with gage-measuring apparatus, especially lead-testing machines. Further coöperation with the Ordnance Department has taken place in the development of an invention covering the manufacture of precision size blocks similar to the Swedish gages. This work has progressed to the extent of completing about 500 gages which are accurate for flatness, parallelism and size within 0.000005 in. It is expected that about 50 sets of gages will be completed about March 1.

b The Motor Transport Division, Quartermaster Department, have submitted for test and certification practically all of their master product parts and master gages. These gages have been stored at the Bureau and dispatched as required directly to manufacturers executing Government contracts for motor trucks and motor truck parts.

c The branch of the Signal Corps which was afterwards organized at the Bureau of Aircraft Production submitted a number of master gages and inspection gages for test at the Bureau of Standards at Washington before they had any inspection facilities of their own. However, practically no gages have been submitted from this branch since January 1, 1918 as the Bureau of Aircraft Production established a gage-testing laboratory in New York in collaboration with the British Ministry of Munitions in United States.

d The Navy Department has coöperated with the Bureau of Standards to the extent of investigating the methods used for measuring gages at the Bureau and in securing technical advice and information on their gaging problems. The Bureau of Standards was asked to calibrate the measuring machine at the Naval Gun Factory at Washington, D. C. The measuring machine referred to is the standard to which all naval guns are manufactured. Practically no gages have been submitted for actual measurement by the Navy Department.

2 *To what extent has the Bureau of Standards responded to the demand made by such departments?*

a Preparations were made by the Bureau of Standards at an early date to handle promptly the test of all munitions which might be submitted by various Government departments. On June 15, 1917, a special war appropriation of $150,000 for gage standardization by the Bureau of Standards was approved by Congress; and on July 8, 1917, apparatus and equipment was transferred to a special building for the testing of munition gages. The first lot of munition gages was submitted on June 16, 1917.

b During the months of June, July, August and September the Gage Laboratory was overorganized, there being more inspectors available than were required for the test of gages delivered during this period. The personnel and equipment was increased as rapidly as was consistent with information which could be obtained from time to time regarding the number of gages likely to be submitted for test from various sources. It was surprising, indeed, to learn of the organization of a separate gage laboratory by the Bureau of Aircraft Production in spite of the fact that the facilities available at this Bureau had been repeatedly called to the attention of responsible officials in charge of aircraft work, especially as the Bureau of Standards had rendered very prompt service in the test of gages submitted by the Signal Corps before they had facilities of their own. In this connection an instance will be cited where a lot of 110 thread gages were submitted on Saturday noon, were tested and delivered with a complete report to the Signal Corps Inspector on Sunday night, the Inspection force being on duty during Saturday afternoon holiday, Saturday evening and on part time the following Sunday.

c Particular pains have been taken to supply information on gages tested to all interested parties. In all lots of gages tested, 8 copies of the report showing the acceptance, rejection or measured dimensions of the gages had been written and in many cases, it has been necessary to make from 11 to 12 copies of these reports. For instance, on gages tested for the Ordnance Department, copies of the reports had been supplied to the gage manufacturer, the contractor using the gages, 2 copies to the Inspection Division, one copy to the Procurement Division, one copy to the Production Division, one copy to the Engineering Division, and one copy to the property officer.

3 *How many gages have been certified for each department? What per cent of rejections?*

a An idea of the amount of work which has been submitted at the Gage Laboratory in Washington is given in the following table which indicates the number of gages which have been received, tested, certified, or rejected:

1917	July	244	1918	May	4917
	August	473		June	5559
	September	456		July	4720
	October	737		August	4106
	November	1735		September	3207
	December	1142		October	3450
1918	January	2519		November	3270
	February	1813		December	1620
	March	3582			
	April	4688		Total	48238

In the above table about 60 per cent could be classed as plain gages (plain, plug, snap, and ring gages); about 20 per cent as profile gages (complicated templets, chamber gages and fixture gages); and about 20 per cent thread gages. Of these gages about 70 per cent were on account of the Army Ordnance Department; 10 per cent were on account of the Motor Transport Division, U. S. Army; about 5 per cent were on account of the Signal Corps; and the remaining 15 per cent were on account of other branches of the Federal Government and industrial concerns having Government contracts. In addition to the foregoing testing, the Bureau has been called upon to inspect gages used in the production of cannon at various points in the field. In this connection over 300 gages were inspected for the 75-mm. field gun at Rochester, N. Y.; and over 600 gages for the 3-in. anti-aircraft gun were inspected at Philadelphia.

b The following table shows the gages received at the various branch laboratories:

		New York	Cleveland	Bridgeport
1918	April	241	....	....
	May	459	....	....
	June	431	....	....
	July	737	276	....
	August	1434	409	48
	September	1225	424	458
	October	1541	360	462
	November	1843	430	441
	December	1665	479	454
	Total	9576	2378	1863

c With reference to the percentage of acceptance and rejection of gages the following figures taken from the test for the Ordnance Department are submitted:

Approved	70 per cent
Rejected	17 per cent
Measurement dimensions reported	13 per cent

4 *How many branches have been inaugurated and where?*

Branch Gage Sections have been inaugurated as rapidly as the need could be determined. The Branch Gage Section in New York

City was opened April 15, 1918 and includes at the present time a complete gage testing equipment with about 25 persons. The Branch Gage Section at Cleveland was opened July 1, 1918 and includes a complete gage testing equipment and, until recently, a personnel of 6 to 8 persons. The Bridgeport Branch Gage Section was opened August 20, 1918, at the request of the Ordnance Department. There is available in this branch a complete gage testing equipment and a working force of 6 people. Both the New York Branch and Cleveland Branch were initiated by this Bureau and have been well supported and fulfilled an apparent need. These Branch Laboratories were organized mainly for the purpose of taking care of the test of gages needed for exigency purposes, such as inspection gages and working gages being secured by Government contractors and needed for the maintenance of production. The inspection of master gages ordered by Government departments has been taken care of in practically all cases at the Laboratory in Washington in order that the Branch Laboratories would not be congested with this work and thereby interfere their functioning.

5 *How fast has the Bureau been able to handle certification? What periods of delay have there been, and if any delay, what were the contributory causes?*

Every effort has been made to render prompt service in the test of gages submitted. In many cases where gages were urgently needed, gages have been received, tested and the report mailed on the same day. The average time of test for the gages submitted at the Bureau of Standards and Branch Laboratories has been 3½ days. In some cases, particularly large shipments of gages have been held for test for a period of about 2 weeks but the delays in this case have most all been due to the fact that drawings were not available for the examination of the gages, and very often gages have been submitted without definite shipping instructions as to their disposal, or with information lacking as to the source of the gages or nature of the test required.

6 *During the reconstruction period and during peace conditions following, what prospect is there of having the Bureau of Standards and its branches continue in this work so as to be a continual benefit to American industry?*

The Bureau of Standards which is a branch of the Department of Commerce is a permanent institution organized for the development, construction, maintenance and custody of standards of measurements, performance and practice. There is no reason why the facilities in a way of gage testing and scientific staff, made available by war conditions, should not be continued to a large extent for the benefit to American industry during the reconstruction period and indefinitely thereafter. In the work of test and certification of gages during the war, an immense amount of data and information has been accumulated, which the Bureau intends to make available to manufacturers in the way of publications, magazine articles and technical papers.

b It is believed that manufactures have, in the execution of Government contracts, come to realize the advantages of interchangeable manufacture where production is large and that the demand for gages and measuring tools will exceed many times the demands for this material before the war.

c Up to this time the energy of the Gage Section of the Bureau of Standards has been devoted mainly to the test and certification of gages. However, it is planned to use the technical staff for the collection of information and data on the practical problems of manufacturers; for the carrying out of experiments and investigations on such problems as the design, manufacture and application of gages; and for research work in the development of new formulas, charts, methods of test, and for the organization of simple and effective pieces of apparatus for general shop use. The Gage Shop at the Bureau of Standards should be maintained for the construction of precision shop reference standards, including end measures, thread gages, various sizes of standard gages decided upon by the National Screw Thread Commission, and other forms of measuring standards. Furthermore, this shop will be of excellent service in connection with the development of new and simplified forms of shop measuring tools and apparatus, and for the test and development of special machinery for producing gages such as thread grinding machines and the like.

d It is planned to continue indefinitely the operation of the Branch Gage Section in the United Engineering Societies Building at New York City and the Branch Gage Section in the Plymouth Building in Cleveland, Ohio. Service for the testing of gages will be available in these Branch Laboratories and in the Laboratory at Washington for the testing and certification of gages submitted by manufacturers upon payment of a nominal fee. With reference to the matter of charging fees for the test of gages, it is a policy of this Bureau to make charges in case the work done is of direct benefit to one or two interested parties. However, when investigations or experiments are conducted, the result will be of general utility to manufacturers, no fee is charged. The continuation of the New York Branch and the Cleveland Branch will also serve as Headquarters for the technical staff in the field, where the application and operation of the various methods and pieces of apparatus devised and utilized by the Bureau of Standards can be explained to representatives of manufacturing concerns. These laboratories will also serve as points with which manufacturers can get in touch with the Bureau of Standards an technical problems arising in their work.

The possibilities in the utilization of the technical staff and facilities available at the Bureau of Standards in Washington, New York City and Cleveland will depend largely upon the demands made by manufacturers and by the general support given to these projects. An appropriation of $150,000 has been requested of Congress for the operation of the Gage Section for the fiscal year ending June 30, 1920, and the work of the Gage Section for the coming fiscal year will depend, of course, upon whether or not this appropriation is made available.

If additional information is desired by your Committee, I would be pleased to have prepared such articles or information as you require. It occurs to me that it might be well for your Committee to transmit part or all of the material presented in this letter to the technical press for publication, and I would like to know if such action is taken.

Respectfully,

(signed) S. W. STRATTON,
Director.

Washington, D. C.,
January 3, 1919.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A. S. M. E.

Research! What Will You Do?

THE Research Committee of the A.S.M.E. has decided to inaugurate several activities and asks the assistance of the membership of the Society in this work.

The research of the last four years in the countries of our Allies and at home has been able to circumvent the hellish devices of the Hun. The work of the layman, the pure scientist and the engineer has developed methods of detection, method of manufacture, processes and devices which were never thought of before. Many have started the solution of special problems which by a further extension may be made general. Some have started problems which have been discontinued now that the active fighting has ceased, and these by a little more work could become of great value.

In many laboratories of our technical schools and universities and of our large industries and of our private investigators there have been research problems worked out which have never been published for one reason or another, and these would be of great value to the profession if announced.

The equipment of some laboratories is especially fitted for a definite kind of research, and if this were known, problems of the nature fitted for the equipment would come naturally to these laboratories, while other problems would go to other laboratories. The knowledge of the equipment is therefore of prime importance. For this reason a survey of laboratory facilities of the whole country should be made.

Many problems are arising each day for which research information is needed. This information is required by those who have equipment and staffs for research, and for such the Research Committee cannot do much, but there are many engineers and manufacturers who are not in a position to undertake the investigation because they lack investigators and apparatus. The problems of such persons should be stated so that those prepared to undertake them can be brought in contact with those who need the data from the investigation.

These are the conditions at present, and to meet them the Research Committee has made the following plans:

1 *Research in Progress.* The Committee desires the members of the Society, the manufacturers who maintain laboratories, the directors of private laboratories and college laboratories and the directors of experiment stations to report to the Committee the research problems on which work is being done. The subjects of these investigations will then be published in MECHANICAL ENGINEERING. The Committee will give case numbers to these investigations and cross-reference them on a card index. In this way it is hoped that the profession will know what work is being done and where these investigations are being made.

2 *Results of Research.* The Committee desires that results of investigations be sent to them for publication in Mechanical Engineering, The Journal of The American Society of Mechanical Engineers. If the investigation is best presented in an article, it will be advisable to so give it. The Committee believes that there are many investigations of a restricted nature which, while not warranting a paper, should be reported in a concise statement of results, with curves or tables, and it is the wish of the Committee that our members coöperate in sending in this information. These results will be numbered in some way for reference so that one may be able to obtain the information rapidly.

3 *Problems to Be Solved.* It is asked by the Committee that those having research problems on which they desire information and on which it is possible to publish the problem will communicate the problem, and this will be properly presented in Mechanical Engineering with a case number. This will bring to the attention of those properly equipped problems on which they may work, and will bring together the person desiring research information and the laboratory equipped by staff and apparatus to do the work.

4 *Laboratory Equipment.* The Committee hopes to publish from time to time statements of the laboratory facilities of various individuals, corporations, colleges and experiment stations so that it may give to the profession a clear idea of the facilities within the various districts of our country. This it hopes will stimulate work and aid those who have problems to place them at a near-by point.

5 *Bibliography.* For those starting research, bibliographies will be prepared by the Society if the scope of the investigation is such that the Council of the A.S.M.E., on recommendation of the Research Committee, approves. On approval by the Committee the request will be made of the Council and the bibliography prepared. A copy of this will be loaned to the person beginning the research for a proper period, and at the same time a notice of the bibliography will appear in Mechanical Engineering, so that any others interested may borrow the carbon copies of the bibliography for a period of two weeks. In this way three or four carbon copies may be made of great value. The original and the carbon copies will be filed for reference in the Library of the United Engineering Societies. The bibliographies will be made from the excellent library of the U. E. S., one of the best technical libraries in the world.

These points are the initial steps in the present plans of your Research Committee. To make them successful you are asked to help. Coöperation and a united front have been successful in winning the war; they have been successful in industry and in trade. The Committee needs the help of each one, and for that purpose it hopes that you will aid in sending in data under any of the four heads. The Committee cannot know the work under way, the results, the equipment or the problems unless you send them the information. The success of this depends on each individual member, on you! Will you help?

Arthur M. Greene, Jr., *Chairman,*
Research Committee.

NEWS OF OTHER SOCIETIES

American Institute of Electrical Engineers

At a meeting of the American Institute of Electrical Engineers held on January 10 in the Engineering Societies Building, New York, Major-General George O. Squier, Chief Signal Officer of the U. S. Army, gave for the first time the history of the achievements of the country in aviation during the war. The address, which was upwards of 30,000 words in length, was given at the direction of the Secretary of War.

General Squier said that 8600 aviators had been trained in this country when the armistice was signed, while in the production of airplanes, 350 firms, employing 200,000 men and women, were engaged. Through this organization it was possible, he said, to produce 14,000 Liberty motors with an equivalent of 5,700,000 horsepower up to November 11. At this date the Army had adopted four airplane types on which production was to have started in the calendar year.

One of the striking accomplishments was the development by the Navy of the naval seaplane or flying boat NC-1. This plane has a wing span of 2400 sq. ft., is equipped with three Liberty engines with tractor screws, and when fully loaded weighs 22,000 lb. It is the largest seaplane in the world and on a recent test made a trip from Hampton, Va., to Rockaway Beach, N. Y., carrying fifty-one passengers. The fifty-first passenger, it is interesting to note, was a stowaway.

After telling how the problems of obtaining spruce, linen, and castor beans were met, General Squier declared that behind the production figures of November 11 there was mobilized in the United States an industrial army of about 350 concerns and corporations employing more than 200,000 men and women.

The Science and Research Division of the Signal Corps at the time of the beginning of the armistice had in progress sixty-four problems, he said. Among the work completed was the designing and development of a new and improved venturi-pitot tube for the use in the determination of air speed.

The satisfactory progress made with the vacuum tube has resulted in a new type of military unit known as a voice-commanded squadron, which is directed by the commander in any manner desired by voice, thus enormously increasing the squadron's efficiency as a military machine.

Aviation in the Future

"If America will but press on into the future, building upon the sound foundations now erected," continued General Squier, "she may lead the world in the development and utilization of aerial navigation for the triumphs of peace.

"By a wise policy of readjustment, utilizing immediately our machines and our surplus aviators for the rapid expansion of the aerial mail and special passenger services, it will be possible to salvage a greater percentage of the money and energy invested for strictly war purposes than for any other feature of our war activities."

Transcontinental and transatlantic flights in dirigibles soon will be a commonplace occurrence, through the more extensive use of helium, a non-inflammable gas.

Now, through the efforts of the Navy Department and the Bureau of Mines, more than 147,000 cu. ft. of helium was ready for use, with plants under construction which would be able to turn out at least 50,000 cu. ft. daily at a cost of not more than ten cents a cu. ft.

Greater safety in transcontinental and transatlantic flights will be made possible through the establishment of upper air stations by means of balloons. By this means air currents can be forecast and accurately gaged. Recent experiments have shown that above the level of 10,000 ft. 95 per cent of the winds, both in the United States and Europe, are from west to east, and often attain a velocity of 100 miles an hour. November 6, at Chattanooga, Tenn., a velocity of 154 miles an hour was discovered at an altitude of 28,000 ft. Preparations are now under way to make similar observations from ships on the sea along the proposed transatlantic route.

American Society of Civil Engineers

The 66th annual meeting of the American Society of Civil Engineers was held January 15 and 16, in the Engineering Societies Building.

As a rule at the annual meetings of the American Society of Civil Engineers only business matters are transacted and addresses of a general nature presented, but not strictly technical papers. This meeting was no exception in this respect.

Mr. Fayette Samuel Curtis, of Boston, was elected president of the society for the coming year.

A subject which evoked considerable interest and resulted in a formal unanimously adopted resolution was the matter of the summary dismissal of about 350 engineer employees of the Public Service Commission for the First District of the State of New York. The Brooklyn Engineers' Club presented to the Board of Directors a series of resolutions which vigorously protested against this act, as being both unfair to the men deprived of their jobs and liable to cripple the engineering activities of the Public Service Commission, which at the present time has on its hands the important work dealing with the construction of the great transportation system of New York City.

This matter is already under consideration by the Engineering Council, and the American Society of Civil Engineers went on record as endorsing the resolutions of the Brooklyn Engineers' Club.

Another matter of interest to the entire engineering profession was brought up before the Society in the resolution offered by R. S. Buck. In this case the society went on record as favoring a policy by which the Government would undertake at the present time extensive public works so as to reduce, or, if possible, entirely prevent the unemployment threatening this country during the transition of the industries from the war basis to the peace basis.

Brig.-Gen. R. C. Marshall, Jr., presented an extensive address dealing with the many difficulties involved in the construction of cantonments and the organization which permitted having this vast work carried out in the comparatively brief space of 90 days under war conditions. In the course of this address General Marshall stated that the experience of the War Department has shown that if it had to deal with one great united engineering society representing the entire profession instead of as at present with 19 independent organizations, the task of the War Department would have been materially lightened in several ways.

HELIUM FROM NATURAL GAS

(*Continued from page 158*)

recounting his experiences and discussing the general theory of the subject, is intensely interesting.

By use of an expansion engine, Claude was able to drop the initial gas pressure to from 400 to 600 lb. per sq. in., or even lower in some of the larger units recently erected for air separation. At these pressures the effect depended upon by the Linde system practically disappears so that, in practice, the Claude system works essentially on a wholly new principle rather than by the superposition of this upon that of the Linde process.

However, as Claude confined himself to one expansion engine,[1] it was necessary for him, with his moderate initial pressure, to locate the engine's gas intake at a level in his interchanger sufficiently low so that the exhaust would reach the lowest temperature desired in the system and still be able to absorb quite an appreciable amount of heat at this temperature.

With the one engine taking its gas from the incoming side of the U, it is also evident that for efficient liquefaction only a part of the gas can be expanded through the engine, for, if liquefaction takes place in its cylinders, expansion to that extent is lost. The remainder of the gas must, therefore, be retained under pressure in the U and cooled down and liquefied by heat exchange with the expanded gas returning as indicated by the spiral line around both legs of the U. The gas after liquefaction in leg *A* is let into leg *D* through the throttle and there under the lower pressure rapidly drops still further in temperature by its own evaporation. Here it undergoes fractional distillation as already explained above.

Jefferies-Norton System

Coming finally to the Jefferies-Norton system, Fig. 6, it will be noted that this differs from the Claude in at least three important points, viz.:

1 The system employs more than one engine (in the illustration three *AE*, *BE* and *CE*), each working through a different temperature range. The number of these temperature steps depends upon conditions, increasing with the total range of temperature to be covered and also with decreasing initial pressure employed.

2 The pressure in the outgoing leg of the U is only enough lower than in the incoming leg to allow for proper control of flow, unavoidable friction, head of liquid in the still trays and the like.

3 The engines work upon the gases after their liquefaction and distillation, thus permitting all the gas to be so treated. Incidentally, this also insures freedom from easily frozen impurities enter-

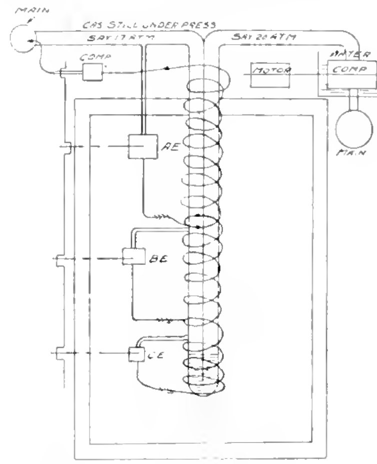

Fig. 6 Jefferies-Norton System

ing the engine valve chambers and cylinders and in many cases greatly simplifies the whole problem of initial purification of the gas to be treated. Engine *C* corresponds in a way to Claude's one-engine system but as the initial pressure used in the system can, on account of its greater efficiency, be much less than the Claude, the temperature range over which this engine works will be much less than in the former. Since, when expanding a given weight of gas between two definite pressures, the work obtainable from it (and consequently the number of calories its expansion will extract from the system) is greater the higher its temperature, engine *A* will extract the most heat from the system and deliver the most power to the crankshaft per unit of gas used and engine *C* the least, which still further emphasizes the importance of this development.

Rough analogies, though suggestive, are often dangerous to accuracy in scientific and technical explanations but without laying any great stress upon it, the following may here be helpful to those not especially familiar with this subject. It was pointed out at the start that a considerable amount of the refrigerative effort which has to be expended in any of these processes is to remove the heat which, despite the best insulation we can put on the apparatus, still leaks in from without. Now in this sense the expansion engines of the last two processes may be thought of as engaged partly in pumping out this heat from the refrigerated system back to the outside, much as mine pumps are kept busy pumping out the water which leaks into a mine. Just as water may be coming in at various levels in the mine so heat is leaking into parts of the system at all levels of temperature. The one engine of the Claude system is analogous to the mine with a single pumping station at the very bottom where all water entering at any part of the mine is allowed to drain clear to the bottom and is then all pumped from there to the surface, while the Jefferies-Norton system is analogous to the installation of several pumping stations at different levels so that water from the upper levels is pumped out over the shorter lifts, thus saving power.

The really salient feature brought out in these diagrams is perhaps the progressive approach toward the ideal of thermodynamic reversibility and the high degree to which this is fulfilled in the basic principles of the last system. There are many other interesting and important features both in the theoretical aspect of the cycle employed and in the details of mechanical construction of the plant at Petrolia which might be given if space permitted, but I fear I am already overstepping reasonable bounds in this particular.

[1] Though this is in many cases compound, having a high- and a low-pressure cylinder.

AMONG THE LOCAL SECTIONS

THE Secretary and the Chairman of the Society's Committee on Research, Prof. Arthur M. Greene, Jr., head of the Mechanical Engineering Department of Rensselaer Polytechnic Institute, have been attending meetings of the Sections and telling of the work of the Society, but more particularly, learning of the wishes of the members. As expressed in the notice sent out for the Chicago Section meeting, "C. W., otherwise known as Calvin W. Rice, will be there, and he wants us all to tell him how to run the Society."

This is the spirit of the visits to Philadelphia, Columbus, Cleveland, Detroit, Chicago, University of Illinois and Indianapolis.

At Detroit, President Cooley gave the principal talk on The Unoccupied Rung in the Engineers' Ladder of Fame.

Splendid interest was displayed in each place, showing that with the prospects of peace one may once more devote his thought to professional and society work.

Further, it was characteristic of many gatherings that men met who had never before known each other, thus directly promoting the feeling of brotherhood which is so essential and one of the principal objects of the Sections.

The Secretary will continue to go out among the Sections, going southeast in February and northeast and southwest in March.

ANNUAL MEETING CONFERENCE OF SECTIONS' DELEGATES

New York, December 4, 1918

Extracts from Reports Rendered by the Delegates

ATLANTA, Robert Gregg, *Chairman:* The Secretary appointed a special Committee of three members to put before the Legislature the matter of securing the adoption of the A.S.M.E. Boiler Code by the Legislature of Georgia.

We have held two meetings this fall, and at the October meeting Mr. Brookes presented a paper on the Code and offered several constructive suggestions looking toward the matter of securing the adoption of the A.S.M.E. Code by the Legislature of Georgia. The Secretary appointed a special Committee of three members to put this before the Legislature.

Regarding membership, we have done active work and our members rarely miss an opportunity to spread the doctrine of membership in the Society. The general attitude, however, is one of conservatism, seeking quality rather than quantity.

In public activities we have coöperated with the Resources and Conversion Section of the War Industries Board through the Society's Committee on Readjustment on War Industries. In Atlanta there is also an Engineering Committee appointed each year by the Mayor to advise the civic administration on engineering problems. This committee is made up of a representative from each of four national societies, and our Section is represented on this committee.

BALTIMORE, W. L. DeBaufre, Vice-Chairman: The Baltimore Section is organized under the constitution and by-laws as laid down by the parent Society. At a meeting of the Section in November, 1918, the Chairman and Secretary were appointed a committee to confer with representatives of the other technical societies and clubs with the object of establishing closer bonds of union between the engineers and chemists of Baltimore and vicinity.

It seems to be the consensus of opinion that it would be desirable for the national society to formulate from time to time certain very definite and limited questions on some particular feature of the relation of the mechanical engineer to his work, to legislation, to education, etc., and submit these questions to the various local sections for discussion.

BIRMINGHAM, W. P. Caine, *Chairman:* The chairman of each of the sub-committees of the Birmingham Section is a member of the Executive Committee. A committee was appointed last year to embody in our constitution the features of the model constitution adopted by the Council. They tried to retain as much of the present one as possible, and in addition to have the election of officers on the same democratic plan adopted by the Society.

It is suggested that speakers interchange between the sections. Could not the Local Sections Committee arrange a tentative tour of speakers that would assist the various program committees in arranging its year's work? Would it not also be a good plan for the Society's Research and Standardization Committees to outline just how they desire the local men to work?

The Section has undertaken the task of securing the passage of a proper bill for the protection of the public from boiler explosions and making the A.S.M.E. Boiler Code the standard of new boilers installed. The Alabama Technical Association has placed itself on record as favoring the adoption of the Boiler Code by the state legislature.

We are on record as offering our support to the City Commissioners in matters of a mechanical nature; and our services were offered to the director of the Conversion Section of the War Industries Board and to the Alabama Manufacturers and Operators Association. We find that our Section creates much more interest in the Society than was in evidence before its organization.

BOSTON, Elmer Smith, *Secretary:* Up to this year our Section included the territory within a radius of ten miles from Boston City Hall but has now been increased to a 25-mile radius, and in a southerly direction the territory extends 50 miles to include Fall River and New Bedford. The territory is particularly rich in membership material and we feel that there are fully 2000 engineers in the Boston Section territory who are eligible for membership.

The results of the efforts of the Membership Committee of the Local Section so far have not been satisfactory. The work has been carried on almost entirely by letter but a new plan is proposed which instead of letter writing will involve a personal interview with the candidate. This will preferably be done by someone personally acquainted with the prospect.

CHICAGO, Arthur L. Rice, *Secretary:* War activity has consisted in assisting in the recruiting of engineering units, men for special service, applicants for officers' training in engineer and ordnance branches, and coöperation in the sale of Liberty Loan bonds. It is hoped that in time a coöperative headquarters and engineering building may be established in Chicago.

CINCINNATI, Prof. A. L. Jenkins, Member of the Executive Committee: Papers of general nature and interest that may be illustrated with lantern slides are preferable to those that are highly technical, involving considerable mathematics. Papers of a highly technical nature, involving equations and complicated diagrams are read in abstract.

From time to time the secretary of the Local Section encloses to the local members a request for suggestions on subjects for papers and men to present them. It is the intention of the Local Committee on Papers to urge members to present papers on subjects about which they are well informed and allow them ample time for their preparation. It is hoped that this policy will tend to eliminate "lack of time" as an excuse, and after a period will begin to bear fruit.

Members are requested to present names of those whom in their opinion are eligible and who would accept membership. Prospective members are approached by members who know them personally and see that their applications are sent in.

CLEVELAND, J. H. Herron, *Secretary:* The first meeting of the Cleveland Section, which was held purely for organization purposes, took place in October; a tentative constitution was adopted, which was subsequently approved. The Cleveland Section is unique in that it is a Section of this Society organized within the Cleveland Engineering Society; in other words, it is called the Cleveland Engineering Society Section of The American Society of Mechanical Engineers. We have been opposed in Cleveland to the Section idea for some years past; we felt that we should not divide our activities, that we should work as one body in

(*Continued on page 193*)

A. S. M. E. COMMITTEE ON LOCAL SECTIONS

ANALYSIS OF ACTIVITIES FOR 1918 REPORTED BY THE DELEGATES TO THE THIRTY-NINTH ANNUAL MEETING

Section	Members Dec. 1, 1918	Chairman and Secretary, 1918	Delegate to Annual Meeting, 1918	Organization by Committees (a) Executive (b) Sub-Committees (c) Joint (d) Coöperating with National Committees	Coöperating or Affiliated Bodies (a) Coöperative (b) Affiliated	Meetings Schedule (a) Technical (b) Joint (c) Public (d) Social (e) Contemplated	Technical Subjects (a) Meetings Held (b) Contemplated	Speakers and Visitors	Public Activities	War Activities	Representative on Aims and Organization Committee

Cleveland, so that we could make the engineering profession as effective in its activities in Cleveland as possible. Therefore, when the Council saw fit to suggest that we might organize the Section within the Cleveland Engineering Society, we were delighted to do so and proceeded forthwith.

A section in our constitution provides for a governing body and executive committee composed of nine members. Three of this committee are members of both the Cleveland Engineering Society and the A.S.M.E., three are members of the A.S.M.E. living within the confines of Greater Cleveland; and the remaining three are selected from the section lying outside of the county in which Cleveland is situated.

We shall have possibly one meeting a month. Every third or fourth meeting we will make an all-day session.

There will be Committees on Membership, and on Meetings, which will, of course, include papers for the meetings, and probably a Committee on Research, although it is our thought that the Research Committee should work under, or our representative should be a member of the national Committee on Research.

Connecticut, E. L. Fletcher, Bridgeport
Charles S. Blake, Hartford
C. K. Decherd, Meriden and the State Section
S. H. Barnum, 2d
Hugh L. Thompson, Waterbury:

We find it always adds greatly to the interest taken in our meetings to have officers of the Society present. We believe that the organization of the Connecticut Section with branches in the several leading cities of the state is along the right lines and will be productive of great good for the Society and the profession.

Detroit, F. H. Mason, *Secretary:* We have an active joint committee consisting of members of the Detroit Section of the A.S.M.E. and the Detroit Engineering Society, which has been arranged as a technical committee to assist the Civic and Local Federal Authorities on the question of "Fuel Conservation" and coöperating with power-plant owners to the end of obtaining fuel economy in their plants.

Just prior to the declaration of war, we had a very active movement afoot here in Detroit, to take over under the general direction of the Detroit Engineering Society, a property which would be developed into a joint engineering building, the plan being to make a home for all of the engineering societies in this district, with very active coöperation between them, and it is expected that this project will be revived just as soon as general conditions will warrant, when such a project could be financed. We believe that such a movement will be directly in line with a sentiment which seems to be growing strongly among the national societies, i.e., to have a very close affiliation between the national societies, in the different localities, and in connection with local engineering societies, and there is no reason why Detroit in the very near future cannot bring about a workable plan.

Erie, M. W. Sherwood, *Chairman:* Effort can most profitably be directed, I believe, toward the securing of additional members. The existence of a strong local engineering society with an initiation fee of only a dollar and annual dues one-fifth of ours has made it difficult sometimes to convince a prospect that the advantages offered by membership in the national society justified the added expense. I believe the best argument is to present the fact that the national organization is to become a prominent factor in the reconstruction of business along new lines made necessary by the war and that new men can best help the great body of engineers, in playing their important part in this work, by joining and supporting a national organization to unify their efforts and secure, through concerted action, results which could never be achieved by any number of small organizations working independently.

The question of reaching the membership outside of the city in which the meetings of the section are usually held, is a problem that I would like to know whether other sections have solved. We occasionally get some of them out to attend meetings, but very few. We have discussed the possibility of holding one of the section meetings in Oil City, although no definite plans have been made thus far. It would be natural for those outside to feel that the section is principally for the benefit of those living where the meetings are usually held.

Indianapolis, L. W. Wallace, *Chairman:* The Local Section has a constitution and by-laws governing its operation. Since this has been formulated, there is no occasion for continuation of like committees.

The Indianapolis Section very enthusiastically entered into the idea of having a joint meeting of the Mid-Western local sections in October, 1918. We were much disappointed that it became necessary to postpone that meeting indefinitely. The unanimous expression is for the holding of that meeting early next spring. The Indianapolis Committee feels that it can be made a great success. We, therefore, strongly recommend that the Sections Committee authorize such a joint meeting as was proposed for October to be held in the Spring, possibly in March or April. We stand ready to put our efforts into the movement in order that it may be a success in every way.

The State Board of Advisory Engineers to the State Fuel Administrator was largely formed through the activities of the members of the Indianapolis Section. An engineer was placed upon the State Council of Defense through a suggestion of the Indianapolis Engineers' Club.

Los Angeles, C. H. Repath, *Representative:* The Research Committee is working out a plan for the publication and preservation of experimental data obtained in the several universities in this section. It has also been suggested that the Society's Research and Standardization Committees outline subjects on which we might obtain valuable information, as there are several mechanical-engineering laboratories at our disposal.

Our Society is represented on the Chamber of Commerce of our City by a Committee on Manufactures, to which the officials of the Chamber can refer for expert information.

Milwaukee, Fred H. Dorner, *Secretary:* The Engineers' Society of Milwaukee appointed a committee to investigate the feasibility of the city owning its own lighting-distribution system. Our society also submitted a report to the city, upon request, of the solution of the automobile-parking problem, for the city of Milwaukee.

We also appointed a committee to investigate the feasibility of closing up the Milwaukee River for lake traffic and building a 50-ft. roadway on each side of the river, with permanent arch bridges instead of the movable bridges now in use.

Minnesota, Jacob A. Teach, *Chairman:* Seventy-five per cent of our membership is concentrated in the cities of Minneapolis and St. Paul, hence the Twin Cities logically serve as the headquarters of the Minnesota Section. Since the inauguration of this Section approximately seven years ago and until the present year, our monthly meetings alternated between the two cities. That was not a good arrangement for two reasons: first, we had no place which we could claim as permanent headquarters; and, second, the average attendance at the meetings was lower than it should have been due to the inconveniently long trip the members from each city have alternately been obliged to take. To correct that situation we made arrangements at the beginning of this season to hold all our meetings at a commercial club in the district midway between the two cities.

New Orleans, E. W. Carr, Jr., *Secretary-Treasurer:* The following is a resolution passed by the Louisiana Engineering Society at their meeting on November 18, 1918:

Whereas, it has come to our knowledge through the city newspapers, that the Commissioner of Public Property of the City of New Orleans, will resign his office on December 1, 1918, and

Whereas, it is our opinion that the administrative and executive duties falling to the Commissioner of the Department of the City Government can be satisfactorily and efficiently performed by a competent and capable engineer as evidenced by the experience of more than a hundred cities in this country that have found it economical and advantageous to employ engineers as City Managers; this result being attributable to the fact that engineers are by education, training and experience qualified to administer to the physical welfare and comfort of communities, and

Whereas, some of the large problems confronting our City Government and calling for solution in the near future, as for instance,

the street railway situation, the disposal of garbage and municipal waste, the introduction of natural gas, are essentially engineering problems.

THEREFORE BE IT RESOLVED: That the Louisiana Engineering Society, both as engineers and as citizens interested in the welfare of our City, respectfully urge upon the Mayor and Commission Council of the City of New Orleans the desirability of electing as Commissioner of Public Property some qualified and competent Civil Engineer who will have an administrative voice in the solution of the economic affairs of our City.

BE IT FURTHER RESOLVED: That the Louisiana Engineering Society tender its hearty coöperation and services to the Mayor and Commission Council in the furtherance of the above object, and that the President of this Society appoint a Committee of four members to serve with himself to represent the Society in any conference on this subject.

Many members of the Louisiana Engineering Society have assisted in problems relating to the development of New Orleans as a port, as a manufacturing center, and as a residential city; to the Industrial Canal now being put through between the Mississippi River and Lake Pontchartrain; the proposed bridge or tunnel across the Mississippi River; the imminent introduction of natural gas to the city from Terrebonne fields; and the extension of our port facilities by means of public warehouses and elevators.

NEW YORK, W. C. Brinton, *Representative:* It may not be realized by delegates from other sections, especially those of smaller size, that the problem in New York is chiefly one of organization. Scarcely a move can be contemplated with our 2200 members but it becomes necessary to handle a large amount of correspondence, telephone or conference work. The New York Executive Committee believes that the number of members in New York City is large enough to justify a paid secretary who will devote most, if not all, of his time to the New York Section. The financial aspect of such a plan must of course be considered and the Executive Committee will be glad to go thoroughly into the subject with the properly constituted authorities.

It is the recommendation of the New York Section Executive Committee that there be a study made of the basic facts regarding the A.S.M.E. membership, activities and finance similar to the report "Association Data Visualized" recently published by the Y. M. C. A. covers practically every phase of the association's activities and many of the curves date back as far as 1866. The New York Section Executive Committee believes that a report of this kind would be of the very greatest assistance, not only to the New York Section but to the Council and the local sections throughout the country. It is of course assumed that work of this kind once started would be kept up so as to be available for all officers and members of committees.

The suggestion that we are working toward here in New York is one which I believe would be feasible in a number of the other cities. For instance, in Boston they have a potential membership, according to estimates, of four times their actual membership. I suppose that that holds true in New York—that our potential membership in New York is certainly four times, in my opinion, what our actual membership is. If that is true, why should not we then organize in such a way as to get in more members, and to do a larger piece of work in our community?

In other words, we feel here that in this Section we have a problem big enough to justify the time of a man all the time as secretary to the New York Section, without regard to the work that he might be able to do on the national matters also. If we can get the combined service of a man in the New York Section, and then to work in on the national problem so as to get any benefits out of the New York experiments, that we might be able to do here, available for the rest of you, I believe it would pay all the better. We do not want to take up anything of that kind unless we have the full sanction of this Committee and the Society as a whole.

ONTARIO, Professor Robert W. Angus, *Chairman:* Our secretary is keeping in touch with the manufacturers' requirements in the way of research, with a view to assisting in any possible way. We are also in touch with the Canadian Government's Industrial Research Committee's work, and hope to coöperate there as well. Our last executive meeting was almost entirely spent on a discussion of how engineers might suggest to the Government means of meeting the great problems incident upon the close of the war, and tide over the period of reconstruction and readjustment.

PHILADELPHIA, John P. Mudd, *Secretary:* The regular election of the Executive Committee of the Philadelphia Section took place at the end of the fiscal year 1917-1918. About the first of August, these men met at the Engineers' Club and began to formulate plans for the coming year. Meetings were held every week or two, until early in September.

The meetings of the Section have, as heretofore, been held on the fourth Tuesday of each month. For the last several years, joint meetings have been held with the other Societies, principally The Franklin Institute, the Philadelphia Engineers' Club, American Illuminating Engineering Society, and American Society of Heating and Ventilating Engineers. It is under contemplation to hold one of the regular meetings in Wilmington, Del. This city contains a very large number of the Philadelphia membership.

It has been our experience that the best way to arouse interest in the Society is through personal interviews.

Local matters pertaining to public relations are first brought before the council of the Associated Engineering Societies. If the council decides that any matter brought before it is of general interest the weight of the entire organization is put behind the movement and greater results are obtained than could be secured by any society alone. If the council decides adversely, the matter is referred back to the section presenting it for such action as the section sees fit to take.

In regard to boundaries we would suggest that there should be some arrangement by which members can be accredited to those sections which are already established.

We would further the suggestion that the A.S.M.E. Council hold regular meetings with the Local Sections, we can think of nothing that would be a greater stimulus to the activities of the Sections.

SAN FRANCISCO, Robert Sibley, *Representative:* With an idea of vastness of country involved and magnitude of engineering effort called forth with problems new to engineering design, members of the Society can readily appreciate how our two sections in the Far West, situated over 3000 miles from the Society headquarters, find contact with the Society as a whole extremely difficult and often find our arguments to induce our fellow-engineers to join the Society of little avail. For under such circumstances since few of our men rarely visit New York City, and since the large number of questions discussed through the journal of the Society are wholly foreign to problems that vex us for solution, it is difficult for local engineers, not members of our Society, to see wherein a fair return is to be received for the annual dues required for membership.

So those of us in the Far West who have this matter at heart see in the fuller development of the local section idea the only ultimate hope for profitable helpfulness both to the member and to the Society as a whole in its work for the betterment of the engineering profession—not alone in New York City but in the far nooks and corners of this broad country of ours. With this ideal in view it would seem that for the ultimate development of Society effort west of the Rockies there should be established as reasonably soon as circumstances will permit duly organized sections in the seaport centers such as Seattle, Portland, San Francisco, Los Angeles, and inland centers such as Spokane, Butte, and Salt Lake City. Such a development of Section activity in the Far West would contribute four vital factors in furthering engineering-society activity:

1 It would interest local members as nothing else can.
2 It would make possible enlarged membership.
3 It would make the Far West more accessible for eastern members who are now either coming to these districts of the West in ever-increasing numbers, or are en route to oriental ports where new activities are engaging our membership.
4 It would immeasurably build up a larger and more useful A.S.M.E., at least, so far as our district of the nation is concerned.

Some concrete examples of the good that has already been accomplished by the Joint Council of the Engineering Societies of San Francisco are as follows:

1 Definite dates have been fixed for the holding of individual section meetings to avoid conflicts in meeting nights.
2 The bringing about of a saving in labor and expense in secretarial work by joint use of addressograph and many economies in clerical help.
3 The joint offering of engineering talent for war service and for historical data now being called for by the War Department.
4 Joint action on necessary legislative matters such as urging the appointment of an engineer member of the California Railroad Commission, an engineer member of the Board of Regents of the State University and legislation affecting the legal status of engineers in the commonwealth of California.
5 The establishing of an effective Service Bureau in which active effort is made to secure accurate information on vacancies open in engineering activities and the placing of capable applicants in employment.
6 The holding of two to three joint meetings of all national engineering societies annually.

In the Far West we realize full well the trying stress financially upon the mother Society to meet the vast outlay necessary to put through the progress of national helpfulness the Society has undertaken. It is the firm conviction, however, of your far-western sections, that more effort and financial assistance devoted to this growing district of our country would not be a matter of charity, but the actual money returns in an immediate influx of new members would not only strengthen the Society nationally but would create an increasing financial revenue in dues that would prove a permanent gain many times the outlay involved, and in addition to this financial assistance we need more personal contact, we need the broadening assistance derivable alone from hearing men of eminence in our profession from eastern centers as well as men familiar to our localities, and we hope some means may be secured whereby the leaders when visiting our district may make themselves better known and advantage taken of their helpful council.

WORCESTER, E. C. Mayo, *Chairman:* During the Fall of 1917 one local meeting was arranged. Instead of having a number of local meetings during 1918 it was decided to devote all our energies towards the preparation of the Spring Meeting, which took place in June. During the summer and fall months of this year a large number of the local members have been interested in the conservation of coal. We were delayed in getting our new Committee for 1918-19 organized and this fact coupled with the unusual interest shown in Worcester on all war activities has taken considerable of our time and prevented any local meetings this fall.

New Year Meeting of New York Section

THE New York Section opened its 1919 season with an enthusiastic and well-attended "New Year" meeting on the afternoon and evening of January 14. The program comprised an address by L. C. Marburg, Chairman of the Society's Committee on Aims and Organization, on the work of the Committee; a paper by Edwin J. Prindle on The Patent Situation in the United States; and a series of brief addresses by W. W. Macon, H. L. Aldrich and A. J. Baldwin on their experiences abroad as members appointed by President Main to represent the Society on a delegation of technical editors who were guests of the British Government on a trip of inspection of the battlefields of Europe and of the manifold industrial activities of England in war time. Mr. Baldwin supplemented his remarks by numerous stereopticon views showing the devastation wrought by the enemy on the cathedrals, towns, factories and mine heads of Flanders and France. Geo. K. Parsons, New York Section representative on the Committee on Aims and Organization, presided over the afternoon meeting. A buffet supper was served at 6:30 p. m.

THE SOCIETY'S AIMS AND IDEALS

L. C. Marburg, Chairman of the Aims and Organization Committee, brought to the attention of the meeting the questions which his Committee is considering in view of the changes which appear to be under way in the viewpoint of engineers as well as among others in the world at large. These questions were very fully reviewed in the last number of MECHANICAL ENGINEERING in the report of Mr. Marburg's address at the Annual Meeting, and in the present address he urged upon his hearers the need for coöperative effort to help solve the problems with which the Committee is confronted; and possibly the greatest of which was that of arousing the membership to the realization of the magnitude of the task and of the necessity for a general and generous response to the Committee's efforts.

The program of the Committee is divided into three main divisions: (a) Relations of the Mechanical Engineer to His Work; (b) Relations of the (Mechanical) Engineer to the Community; (c) Relations of the Mechanical Engineer to Other Engineers.

Without changing the meanings of these headings the speaker said we might call the first one "professional aims"; the second one, "public aims"; and the third one, "organization."

Under professional aims, it is the purpose of the Committee to determine from the membership what subjects the Society is now interested in or should be interested in more than it has been in the past; for example, with regard to standardization and research it is expected to learn from the committees on these subjects what they believe ought to be done in addition to what has been done. Then, as to the scope of papers and discussions which are supposed to relate to "progress in the art of mechanical engineering and allied sciences," in what way is "allied sciences" to be interpreted? Does it include economics and welfare work and other general subjects which the Society frequently discusses? If not, should not the scope of the Society be redefined?

Shall MECHANICAL ENGINEERING be published more frequently than at present? In close connection with this is the question of the classification of literature so that articles may readily be found.

In conducting and assisting research, another topic, should the individual societies carry on this work or should it be done by united action as in Great Britain through the suggestion of the Conjoint Board of Scientific Societies?

The same thing holds also with respect to standardization. Other subjects are education and special training, and legislation and jurisdiction affecting the engineering profession.

In the second major group, the Relations of the Engineer to the Community, should engineers as a group take a greater interest in public affairs and make available to the community the experience of the group in matters with which they are familiar?

Under the final heading, Relations to Other Engineers, in what way should united action be secured? Should there be a union of the four founder societies, or should other organizations be included, including certain of the local societies? Under this heading would come also social activities—the advisability of having clubs with exchange privileges, so that an engineer from one city, connected with one club, could go to a club in another city.

At the conclusion of Mr. Marburg's address, J. E. Johnson, Jr., in response to the chairman's request for suggestions, said that the present seemed to be a time of great unrest in the engineering profession all over the country, comparable to the political unrest in Europe. As Mr. Marburg had said, it would be comparatively simple to consolidate the various societies—they were already partly consolidated, and what good had resulted? There was the Engineering Council and also the Engineering Foundation. The latter had been established to promote research, but the main thing it had done within his knowledge was to finance the National Research Council until the Government had taken it over.

Similarly, the Engineering Council was supposed to represent all the engineers, but on one important occasion, when they had been requested to coöperate with the legal and medical professions in protesting to Congress against the imposition of the unjust 8 per cent tax on professional incomes, they had done nothing, so far as he was aware.

If the engineering societies in the broad sense, along with some of the economic and other related societies, were so consolidated that membership in each would mean membership in the national

society, and every district of a given number of engineers had a head who was elected a member of the Engineering Council, meetings of the latter could be held at which the various problems could be discussed and results obtained. The funds of the Engineering Council could be put to no better purpose than to pay the traveling expenses of real representative men from all over the country to come to New York and discuss what should be done and discover means for doing it.

Charles Whiting Baker said that as a member of the Engineering Council he could assure the previous speaker that the income-tax matter had been extensively considered by that body. There was no question as to its injustice, but as to whether anything would be accomplished at that time by making a protest; and the majority of the Council felt that with the war going on it would perhaps be unwise and unpatriotic for engineers as a class to protest against any tax assessed on them, however unjust.

As to the work of the Council, it had been in session that very afternoon dealing with the matter of the abrupt dismissal of some 370 engineers engaged in rapid transit work as a result of unwarranted interference by the Board of Estimate and Apportionment, and it proposed to do everything in its power to right that wrong and let the public know what was going on.

He desired to impress on those present, however, that while the Engineering Council was created to care for just such matters, it was the duty of every Local Section of the Society and the Society itself to work for the Council.

"If something comes up in any locality where the Section can speak," said Mr. Baker, "it is the business of that Section to adopt resolutions and appoint committees to see the men who have charge of affairs—use their influence; and if, say, twenty societies adopt resolutions on the same thing, bringing into play the cumulative effect, the engineer will go forward more rapidly in doing the things he wants done than if he waits for the general movements in his own organization. Let him use his organization instead of trying to do too much to consolidate. There is danger of relying on consolidations and the force of great numbers. The fact is that oftentimes a big organization finds it difficult to do things a small one can do very well."

The discussion closed with the proposal of the following resolution by J. E. Johnson, Jr., which was duly seconded, put to vote and carried:

Resolved, That arrangements be made looking to a joint meeting of the New York sections of the four Founder Societies (not necessarily exclusive of some of the other representative societies) to be held at a later date.

Charles Whiting Baker said that if such a meeting was to be held, someone must have charge of it, and he accordingly offered the following resolution which was put to vote and carried:

Whereas, The work of the Committee on Aims and Organization is invested with matters of most fundamental and primary importance to our Society, be it

Resolved, That the New York Section Executive Committee be empowered to appoint a sub-committee to assist our representative, Mr. G. K. Parsons, to the end that the members of our Section may be fully informed and have ample opportunity to voice their ideas on Aims and Organization of the Society.

The Patent Situation in the United States

At the conclusion of the discussion, Mr. Edwin J. Prindle presented his paper on the patent situation in the United States, in which he said that the desirability of increasing the incentive to produce inventions had been shown by the exceedingly important part they had played in the war. Improvement in the efficiency of our Patent Office and patent system would work to the improvement of the inventor's position, and important among the matters that would contribute to this end would be a single court of appeals, making an independent institution of the Patent Office, increasing the force and salaries in the Patent Office, and changes in the law providing compensation for infringement of patents.

Mr. Prindle is a member of the Committee of the National Research Council appointed at the request of the Society of Patent Office Examiners to investigate the Patent Office and its system and recommend provisions for increasing the efficiency of the Patent Office. Although his paper embodied only his personal views, it may fairly be interpreted as representing also the views of the Committee. Since the paper was presented the report of the Committee has been officially approved by the National Research Council, the Engineering Council and the Commissioner of Patents, and an abstract of it is therefore given elsewhere in this number.

Trip of Technical Editors to England and France

At the evening session, W. W. Macon, who presided, explained that the delegation of which he had been a member consisted of 15 trade and technical journalists who had been invited by the British Government to come and see with their own eyes and then report to their readers the unstinted efforts Great Britain was making to insure a victory in the titanic struggle in which she and her allies were engaged. After referring to the varied forms of entertainment that had been accorded the delegation, the visits they had made to engineering works, to the Grand Fleet and the battlefields of Flanders and France, and to a projected cross-Channel flight that had to be abandoned on account of weather conditions, he introduced Mr. Aldrich as the next speaker.

Mr. Aldrich described strikingly the 14-day voyage of the party on the zigzag course made necessary by the submarine menace. Arriving in England he was first impressed with the stupendous amount of work that had been performed by women during the war. What the outcome would be when the troops returned was conjectural, but it was believed that there was much work, especially of the lighter sort, that would continue to be done by the women. In the matter of trade there was a feeling that there would be severe competition in export trade and in shipbuilding with the United States after the war, but this was tempered by the reflection that there would no doubt be room for all.

Great Britain had expended a third of her gross wealth in "carrying on" and the taxes already high would doubtless have to be supplemented by tariff imposts. The income tax was very high and began at very low incomes, but so far it had not impinged on labor, although the incomes of many of the workmen were well above the lower taxable limit.

American engineers had accomplished things believed impossible in France, both in battle and in works of construction. At St. Nazaire, on the Loire, where our troops disembarked, tidal gates maintained a 20-ft. depth of water in the river. Along the miles of water front utilized there were innumerable cranes of every size and description; in fact, the handling facilities were the most complete he had ever seen. Our engineers had fitted up a huge locomotive repair shop in which 14 engines could be assembled in a day. Many German prisoners were employed in this work.

The speaker commented on the deliberateness with which the French were accustomed to bring about changes, and instanced the case of a needed concrete reservoir that was constructed by American engineers at St. Nazaire and completed in less time than it would have ordinarily taken to obtain the necessary authority. Miles of unnecessary railway haul were similarly saved by building a cut-off around an angle in the road to Paris. In both cases the engineers had gone directly to the highest authorities and by their forcefulness had eliminated the red tape of procedure.

In the six months ending on September 1 the Americans had laid 250 miles of railway track and had constructed, in a swamp above St. Nazaire, 180 huge warehouses having a total of over 50,000,000 sq. ft. of storage space. There were over 20,000 American freight cars in France and several thousand locomotives. Thousands of motor trucks were also used, and in one day 1500 were received from America.

Mr. Baldwin, who was then presented by the Chairman, said that on the arrival of the delegation, England was without lights and in gloom. Three days later, the armistice having been signed, they went almost delirious with joy at their release from the aircraft menace.

The party had been shown the Grand Fleet—an imposing

spectacle with its boulevards of battleships and avenues of cruisers—and had, among other places, been taken to the vast shipyards of Glasgow. It had been their intention to cross the Channel in a huge airplane of 127 ft. spread and a capacity of 40 passengers—built for bombing Berlin—but weather conditions forbade.

On the Continent they rode over the battlefields in motor cars and visited practically every section from Flanders to Lorraine, passing through La Bassée, Ypres, Vimy, Souchez, Le Catalet—where the old 7th Regiment of New York and the 23d of Brooklyn were the first to cross the Hindenburg Line—Rheims, Hill 108 with its two miles of winding underground passages, and so on. Among the souvenirs he had acquired were two German shells bearing the date of their manufacture—15 years before the war, which seemed to him to be evidence of a sinister purpose long under consideration.

Mr. Baldwin then had shown the photographic views mentioned earlier in this account, and accompanied their presentation with brief descriptive comments. Continuing his address, he said that industrial conditions in Europe were much the same as in America, but more intensified. All countries were looking for export markets and the competition would be keen, but the world's shops and warehouses were empty now and there would be work for all.

In closing, he spoke of the word "dependence" as typifying the conditions prevailing in the old, dark days of Europe, out of which its peoples had struggled after long years into "independence." But our own magnificent national experiment had shown that there was something in the relations between states that transcended in importance even the concept of independence, and this was "interdependence"; and from the proceedings at Versailles he believed would issue the charter that would establish this salutary relation and insure its continuance for generations to come.

Fuel Meeting at Boston

The Boston Section held an interesting meeting on Fuel on December 19, at the Wentworth Institute. David Moffat Myers, Mem.Am.Soc.M.E., Advisory Engineer to the U. S. Fuel Administration, delivered the address of the evening on the subject of Results of Fuel Conservation. Remarks were also made by Prof. A. E. Norton of the Massachusetts Institute of Technology and by Perry Barker, consulting fuel engineer. At the close of the address a motion picture was shown, entitled Coal is King. Mr. W. W. Crosby presided.

Mr. Myers reviewed the successful results of conservation that had been effected by the Fuel Administration and showed the urgent need for a continuation of the work so successfully begun, closing with suggestions as to the broad scope which it might assume in the future. The following summary brings out these points:

As nearly as can be estimated from the reports from the states, the first six months of the active prosecution of the program resulted in an annual saving of 7,000,000 tons of coal in the power plants, 1,000,000 tons on the railroads and 4,000,000 tons in such items as the introduction of the skip-stop on electric railways, the reärrangement of power plants to avoid duplication, the substitution of central power for that produced by isolated plants where that proved advisable, and the larger utilization of water power and savings in domestic consumption. These savings were all in the direction of constructive conservation which has for its slogan "Maximum Production of Industry with Minimum Waste of Fuel." They were in addition to such savings as were effected by the curtailment or restriction of industry and were only a fair beginning of what may be done by continuing the practice of steam and fuel economies. It will be comparatively easy to increase this figure to 50,000,000 tons a year. The latter at $5 per ton would pay one-quarter of the interest on our national war debt.

It was thought by many when the Government took up the plan for inspection of power plants that there might be some resentment on the part of owners with the idea of having their private business interfered with by volunteer engineers in the service of the Fuel Administration. But owing to the patriotic spirit of helpful coöperation with the plant owner with which the state authorities and the administrative engineers and their committees introduced and carried on their work, this objection was overcome and they gained the hearty backing and good will of the manufacturers.

Letters are being received in Washington from far and wide asking that some scheme of fuel conservation applicable to power plants be adopted as a permanent measure. Many manufacturers have written appreciatively of the saving they have been able to effect as a result of instructions received from the volunteer inspectors of the Fuel Administration, or from the standard recommendations of the administration.

From the beginning of the campaign it has been in the minds of engineers that a second phase of the power-plant program might soon become appropriate. The efficiency of any process such as the production of energy is equal to the efficiency of operation multiplied by the efficiency of the equipment. That is to say, the efficiency of the man multiplied by the efficiency of the machine.

We have so far been considering almost exclusively the efficiency of the man behind the machine or the man in front of the boiler or the man on our factory committee, but up to the present time have given little or no official attention to the efficiency of the equipment. This question involves the matter of initial design and proper supervision of any changes that are contemplated in a plant in order that they may be made strictly in line with what will produce the highest efficiency in the use of fuel. Just before the armistice was signed Mr. Myers had proposed this question for discussion by the Committee of Consulting Engineers of the Engineering Council who now have the matter under advisement.

The general idea is to formulate what might be termed "A Ten Commandments of Power-Plant Design," treating only of fundamentals and not of specific design. The reason for desiring such a measure is obvious to any engineer. Time and time again we have all seen so-called "improvements" installed by manufacturers using steam-consuming or steam-generating equipment entirely unsuited to the conditions under which they are to be used. When this is done it means that for years and years to come an entirely unnecessary waste of fuel will continue owing to the ill-advised installation.

The same reasoning of course applies to new plants. Each case requires an individual diagnosis by a competent engineer and preferably one whose interest is solely that of the purchaser. At the same time, after making his diagnosis, a competent engineer will make recommendations based on certain fundamentals and it is these basic fundamentals which we now desire to formulate. The programme of conservation cannot be considered comprehensive unless it treats both of operation and equipment.

In closing, Mr. Myers told what had been done or was contemplated in issuing bulletins and moving-picture films for instruction purposes. A 50-minute film showing good and bad operation in boiler plants had been prepared, and nine engineering bulletins were announced, but most of these were now at press and not yet ready for distribution. The subjects are as follows:

Boiler and Furnace Testing
Stoker Operation
Boiler-Room Accounting Systems
Oil Burning
Fuel-Gas Analysis
Saving Fuel in Heating Systems
Saving Steam and Fuel in Industrial Plants
Burning Mixtures of Anthracite and Bituminous
Boiler-Water Treatment.

It is understood, also, that the valuable bulletin produced by the Massachusetts Advisory Committee is being reprinted for general distribution by the Washington administration.

Enlisted in the service of fuel conservation have been 1500 volunteer engineer inspectors of power plants, many of them

members of this Society, in addition to the several thousand acting on town and factory committees.

Members of the A.S.M.E. have been in charge of the power-plant program as Administrative Engineers in Massachusetts, New York, Pennsylvania, Minnesota, Missouri, Indiana, Maryland, Ohio, Illinois, Tennessee, Virginia and Florida.

The Fuel Administration has received advice and help through the Committee of Consulting Engineers of the Engineering Council in the initial creation and further development of its national plan of conservation. The average power-plant owner did not realize the possibility of important economies to be readily accomplished in his plant until the engineers working solely in the interests of humanity devised a system of education and of personal assistance to him.

From start to finish this has been the service primarily of engineers. It has been a big success, and of great value to our country in her time of need.

If the work of conservation is to be continued and further developed as a widespread permanent institution in such manner as to meet peace conditions satisfactorily, the engineers must devise suitable ways and means, for the country now looks to them with increased confidence.

We should look forward to the future recovery and utilization of the valuable by-products of coal resulting from its low temperature distillation. No raw coal containing these by-products should be burned directly under boilers. The resulting carbonized coal should be the boiler fuel of the future. This is one of the greatest steps toward true conservation of fuel ever inaugurated and should be developed as rapidly as possible.

Water powers should be further developed and utilized, although according to Steinmetz, even when these resources are utilized to the ultimate extent they can care for only a very small fraction of the power demands of the future, and coal will always of necessity remain our mainstay for heat and energy.

Coal is a national resource, a common possession of the people. It is unfair that a progressive plant owner should go to great pains and expense to use his share efficiently while his neighbor continues to waste extravagantly in a badly designed plant and by improper management.

These, briefly, constitute some of the problems before the country today and Mr. Myers expressed his confidence that they can and will be solved by engineers.

Meetings of Sections

ATLANTA SECTION

The Atlanta Section held its regular monthly meeting on Friday, December 27, in the Lecture Room of the Carnegie Library.

At this meeting our Chairman made a report covering his recent trip to New York as the Section's delegate, and our delegate to the Committee on Aims and Organization also reported.

William J. Neville,
Secretary.

BALTIMORE SECTION

A meeting of the Baltimore Section was held on December 18, at which Mr. Hess read an interesting paper on Electric Furnaces as Applied to Steel Making.

On January 27 the Secretary, Mr. Rice, attended a meeting of the Baltimore Section, and addressed the members informally.

A. G. Christie,
Secretary.

BIRMINGHAM SECTION

J. R. McWane and Oscar Wells were the speakers of the evening on January 23, when the Birmingham Section held a meeting at the Tutwiler Hotel. The addresses of these gentlemen were on the subjects of labor and finance. J. J. Greggan read an abstract of President Main's President Address, Broader Opportunities for the Engineer.

James W. Moore,
Secretary.

BOSTON SECTION

Meeting held on December 19 on Fuel. Reported elsewhere in this issue.

BUFFALO SECTION

An interesting meeting was held by the Buffalo Section at the Hotel Statler, on the evening of January 29. The address of the evening was delivered by Nathan L. Lieberman, on the subject Horse Power Requirements of Aeroplanes and Power Consumption through Parasite Resistance.

W. W. Boyd,
Secretary.

CHICAGO SECTION

A get-together meeting of the Chicago members was held on Monday evening, January 13, at the Engineers' Club. The meeting was preceded by an informal dinner, at which the members met Mr. Rice, the Secretary of the Society.

On January 27, M. J. Kermer, Mem.Am.Soc.M.E., delivered a timely address on Sugar Manufacturing.

Arthur L. Rice,
Secretary.

CONNECTICUT SECTION

Bridgeport Branch

The Bridgeport Branch held a meeting on industrial management on December 18. J. C. Spense of the North Grinding Company delivered an address on Vestibule Schools, Prof. H. B. Bogell of Yale University delivered an address on The Education of Radio Operators in Connection with Airplanes, A. W. Lebouef, Educational Director, Remington Arms U. M. C. Company, delivered an address on Shop Education.

C. F. MacGill,
Secretary.

Hartford Branch

Lieut.-Com. D. C. Buell delivered an interesting address on The 50-Caliber 14-in. Navy Guns with Railway Mount before the members of the Hartford Branch.

Maynard D. Church,
Secretary.

New Haven Branch

A meeting of the New Haven Branch was held at the Mason Laboratory on Wednesday, January 8, at 8 p. m. Douglas K. Warner, Jun.Mem.Am.Soc.M.E., read a paper on The Friction of Ball Bearings. This paper described several machines that have been used to measure the friction of ball bearings and discussed the characteristics of this kind of friction.

E. H. Lockwood,
Secretary.

Waterbury Branch

A luncheon meeting was held at the Hotel Elton on November 25, at which the officers for the fiscal year 1918-1919 were elected.

On Monday evening, January 6, there was held in the hall of the Mattatuck Historical Society a meeting to which were invited the Civil, Chemical, Electrical, Gas, Mining and Mechanical Engineers residing in that center. An interesting address was given, describing Waterbury's Water Supply.

Hugh L. Thompson,
Secretary.

DETROIT SECTION

A meeting of the Detroit Section was held on Saturday evening, January 11, at the Detroit Board of Commerce, at 8.15 p. m. There were two speakers of the evening, viz., Dean M. E. Cooley, University of Michigan, President of the Society, and Mr. Calvin W. Rice, Secretary. Dean Cooley spoke informally on An Unoccupied Rung in the Engineer's Ladder of Fame. Mr. Rice delivered an address on the subject of Broader Opportunities for the Engineer.

The meeting was preceded by an informal dinner at 6.30.

Frederick H. Mason,
Secretary.

INDIANAPOLIS SECTION

An informal meeting was arranged for January 15, to give the Indianapolis members an opportunity to meet Secretary Rice, and talk over with him problems of the Section, plans for the Spring meeting, etc.

L. W. Wallace,
Secretary.

MILWAUKEE SECTION

The regular monthly meeting of the Engineers' Society of Milwaukee was held under the auspices of the Milwaukee Section of the A.S.M.E. on Wednesday evening, January 15, at 8 o'clock, at the City Club.

Henry L. Dale, Major of Engineers, U. S. A., gave a talk on Engineering Experiences at the Front. A buffet luncheon was served for the convenience of the members.

Fred. H. Dorner,
Secretary.

MINNESOTA SECTION

An illustrated lecture was given on December 17 by Professor E. H. Comstock, School of Mines, University of Minnesota, the subject being Mining Iron Ore in Minnesota.

Professor Peter Christianson, also of the University of Minnesota, delivered the address of the evening on January 6. The meetings were held at the Section's regular meeting place, the Midway Branch of the St. Paul Association of Commerce.

Ray Mayhew,
Secretary.

NEW YORK SECTION

Meeting held on January 14. Reported elsewhere in this issue.

PHILADELPHIA SECTION

Secretary Rice attended the meeting of the Philadelphia Section held at the Engineers' Club, on Tuesday, January 28. The address of the evening was delivered by William B. Dickson, Vice-President and Treasurer of the Midvale Steel and Ordnance Company, the subject being Relations between Employer and Employee.

John P. Mudd,
Secretary.

PROVIDENCE ENGINEERING SOCIETY

The Power Section held a meeting on January 7 in the rooms of the Society, at 8 p. m. E. L. Woolley, Assistant Superintendent of the Providence plant of the Bethlehem Shipbuilding Corporation, spoke on Work Accomplished at Providence for the Emergency Destroyer Program. Mr. Woolley's address was of singular interest to members of the profession, informed for the first time of the splendid engineering achievements which of necessity were not generally known during the war.

W. A. Kennedy,
Secretary.

WASHINGTON, D. C.

An organization meeting of the members residing in the District of Columbia was held on December 9. An informal dinner was followed by a meeting at the Interior Building, which was addressed by Secretary Rice, Spencer Miller, the Council's official representative to the occasion, Dr. Stratton, Director of the Bureau of Standards, who spoke on the work of the bureau during the war, and Major O. B. Zimmerman, who read a paper on the new fuel.

At the January meeting this petition was presented to the Council, with the approval of the Committee on Local Sections, and the following Executive Committee authorized: Dr. S. W. Stratton, Chairman, George A. Weschler, Secretary, H. L. Whittemore, Arthur E. Johnson, J. K. Klinck.

Meetings of Student Branches

Now that the colleges are returning to normal conditions and the period of demobilization is taking place, Student Branch activities are being resumed. The following meetings have been held:

BUCKNELL UNIVERSITY

November 4, 1918. A business meeting was held at which the following officers were elected for the Student Branch: Prof. B. F. Burpee, honorary chairman; R. C. Corrulla, chairman and C. W. Withington, secretary.

Mr. R. C. Corrula gave a very interesting talk, after which the senior mechanical engineering students decided to attend the Annual Meeting of the A.S.M.E. to be held in New York.

Prof. F. E. Burpee gave a brief talk, which was followed by a social gathering.

January 6. Plans were made for a reception and dance to be given by the Student Branch later in the year, and also an illustrated lecture to be given during the month of January.

Mr. H. R. Pars gave a brief talk on the Annual Meeting of the A.S.M.E. in New York and the inspection trip taken by the students of Bucknell who attended the Annual Meeting.

Clyde W. Withington,
Branch Secretary.

JOHNS HOPKINS UNIVERSITY

The following officers were elected for the Student Branch, year 1918-19: Prof. A. G. Christie, honorary chairman; W. D. Cook, chairman; H. Bloomsburg, vice-chairman, and H. E. Weaver, secretary-treasurer.

Harry E. Weaver,
Branch Secretary-Treasurer.

LEHIGH UNIVERSITY

The following officers were elected for the Student Branch, year 1918-19; Prof. P. B. de Schweinitz, honorary chairman; B. P. Lauder, chairman; C. T. Hunt, secretary, and C. D. Mertz, treasurer.

P. B. de Schweinitz,
Branch Honorary Chairman.

LELAND STANFORD, JR., UNIVERSITY

November 12, 1918. Several meetings had been planned for earlier in the semester, but due to the introduction of the Students Army Training Corps into the University, the meetings had to be postponed until finally the above mentioned successful meeting was held.

The following officers were elected: Prof. W. F. Durand, honorary chairman; Chever Kellogg, chairman, and C. D. Howe, secretary-treasurer. President Kellogg then conducted the remainder of the meeting, on topics concerning the welfare of our Society.

C. D. Howe,
Branch Secretary-Treasurer.

UNIVERSITY OF MICHIGAN

The following officers were elected for the Student Branch, year 1918-19: Prof. J. E. Emswiler, honorary chairman; D. M. Ferris, chairman; J. T. Huette, vice-chairman, and A. D. Althouse, secretary-treasurer.

J. E. Emswiler,
Branch Honorary Chairman.

UNIVERSITY OF MINNESOTA

The following officers were elected for the Student Branch, year 1918-19: Prof. J. J. Flather, honorary chairman; George W. Bierman, chairman; H. B. Abrahamson, vice-chairman; Ross M. Foltz, secretary; Milton S. Wunderlich, corresponding secretary, and Arthur Baker, treasurer.

J. J. Flather,
Branch Honorary Chairman.

UNIVERSITY OF MISSOURI

The following officers were elected for the Student Branch, year 1918-19: Prof. H. Wade Hibbard, honorary chairman; Will Copher, chairman, and K. K. King, secretary.

H. Wade Hibbard,
Branch Honorory Chairman.

UNIVERSITY OF NEBRASKA

The following officers were elected for the Student Branch, year 1918-19: Prof. L. F. Seaton, honorary chairman; V. E. Kauffman, chairman; W. L. Miller, vice-chairman, and H. M. Glebe, treasurer.

L. F. Seaton,
Branch Honorary Chairman.

NEW YORK UNIVERSITY

The following officers were elected for the Student Branch, year 1918-19: E. McCarthy, chairman; W. W. Damm, vice-chairman; A. A. Landi, secretary, and T. Tottis, treasurer.

A. A. Landi,
Branch Secretary.

OHIO STATE UNIVERSITY

The following officers were elected for the Student Branch, year 1918-19: Prof. Wm. T. Magruder, honorary chairman; Franklin H. Cover, chairman; Howard Orth, secretary, and Victor L. Dannell, treasurer.

Wm. T. Magruder,
Branch Honorary Chairman.

PENNSYLVANIA STATE COLLEGE

Three meetings have been held by the Student Branch since the college year opened, the first two being business meetings at which plans were discussed for carrying on the activities for the year, and the following officers were elected: Prof. J. O. Keller, honorary

chairman; H. W. Parthemer, chairman; I. A. Karam, vice-chairman; C. W. Moore, secretary; R. H. Schmidt, corresponding secretary, and R. Y. Sigworth, treasurer. At the third meeting Professor Fessenden gave a very excellent talk on Motor Transport Service.

R. H. Schmidt,
Branch Corresponding Secretary.

POLYTECHNIC INSTITUTE OF BROOKLYN

November 1, 1918. The first meeting of the Student Branch was very well attended owing to the fact that a great many of the S. A. T. C. students were excused from evening study to attend the meeting. Professor E. W. Church delivered a talk on Submarine Construction in which he told of the various types of submarines and the distinguishing features of each type.

Professor W. D. Ennis, formerly Major in the U. S. Ordnance Department, gave a talk on The Gun as a Gas Engine. He also explained the structure of powder and compared the energy produced by a gun to that produced by a gas engine.

The following officers were elected for the Student Branch: Nathan N. Wolpert, chairman; J. P. Minotty, vice-chairman; Ben Offen, treasurer; M. J. D'Aiello, secretary.

Nathan N. Wolpert,
Branch Chairman.

RENSSELAER POLYTECHNIC INSTITUTE

The following officers were elected for the Student Branch, year 1918-19: Prof. Arthur M. Greene, Jr., honorary chairman; R. I. Todd, chairman; J. M. Dewey, vice-president; C. G. Bragaw, secretary, and J. L. Smith, treasurer.

A. M. Greene, Jr.,
Branch Honorary Chairman.

STATE UNIVERSITY OF IOWA

The following officers were elected for the Student Branch, year 1918-19: Prof. S. M. Woodward, honorary chairman; J. F. McLaughlin, chairman; W. J. Hohl, vice-chairman, and I. C. Jones, secretary-treasurer.

S. M. Woodward,
Branch Honorary Chairman.

THROOP COLLEGE OF TECHNOLOGY

November 20, 1918. A business meeting was held at which the following officers were elected: Prof. W. H. Adams, honorary chairman; Donald D. Smith, chairman; R. T. Knapp, vice-chairman; Roscoe R. Rockafield, secretary, and L. Erb, treasurer.

Roscoe R. Rockafield,
Branch Secretary.

WASHINGTON UNIVERSITY

The following officers were elected for the Student Branch, year 1918-19: Prof. E. L. Ohle, honorary chairman; Sidney Weiss, chairman; Herbert A. Strain, vice-chairman; Wm. J. Anderson, Jr., secretary, and Donald B. Baker, treasurer.

Wm. J. Anderson, Jr.,
Branch Secretary.

UNIVERSITY OF WASHINGTON

The following officers were elected for the Student Branch, year 1918-19: Prof. E. O. Eastwood, honorary chairman; Fairman B. Lee, chairman; C. P. Rummel, vice-chairman; E. E. Bissett, secretary, and Lester R. McLeod, treasurer.

E. O. Eastwood,
Branch Honorary Chairman.

WORCESTER POLYTECHNIC INSTITUTE

The following officers were elected for the Student Branch, year 1918-19: Prof. W. W. Bird, honorary chairman; Raymond B. Heath, chairman; Robert A. Peterson, vice-chairman; Stanley N. McCaslin, secretary; Thos. H. Ewing, treasurer, and Prof. H. P. Fairfield, corresponding secretary.

H. P. Fairfield,
Branch Corresponding Secretary.

YALE UNIVERSITY

The following officers were elected for the Student Branch, year 1918-19: Prof. L. P. Breckenridge, honorary chairman; J. V. Jenks, chairman, and W. L. Austin, Jr., secretary-treasurer.

L. P. Breckenridge,
Branch Honorary Chairman.

CONTROL OF BOILER OPERATION

(Concluded from page 141)

to determine where the loss due to a definite increase in CO will overbalance the gain from an increase in CO_2 making the CO probable.

Assuming, for example, that under the furnace and fuel conditions existing when Tests A and B were made 14 per cent was the safe limit for CO_2 for complete combustion, how much CO will it take to overbalance the benefit of raising the CO_2 to 16 per cent, assuming $T - t = 450$ deg.?

Applying Formula [4], it is found that there is a gain of $\left[\left(0.24 + \frac{58.46}{14}\right) - \left(0.24 + \frac{58.46}{16}\right)\right] \times 450 = 234$ B.t.u., and Formula [7] shows that this gain would be overbalanced by $10{,}150 \times \frac{P_c}{16 + P_c} = 234$, from which $P_c = 0.38$ per cent. Therefore, if the increase of CO_2 from 14 to 16 per cent cannot be accomplished without at the same time increasing the percentage of CO by 0.38 per cent, there is no gain in heat to the boiler.

But since there is no definite relation between the percentage of CO_2 and CO, it follows that within proper limits, depending on the construction of furnace, method of stoking, kind of fuel, air control, etc., maximum CO_2 can be attained without appreciable amounts of CO if the fireman exercises proper care and judgment. What these limits are must be ascertained by experiment for each plant, and if the construction of furnace and method of stoking vary appreciably it may be necessary to determine the maximum economic percentage of CO_2 for each boiler. But such determination is of small avail unless the firemen are properly instructed how to get maximum CO_2 with a negligible percentage of CO and have continuously brought to their attention the percentage of CO_2 they are getting.

THE PATENT SITUATION IN THE U. S.

(Concluded from page 139)

Addendum

To the Editor:

Since the action of the National Research Council and of the Engineering Council approving and adopting the report of the Patent Committee of the National Research Council, at which time the report bore the unqualified approval of the Hon. James T. Newton, Commissioner of Patents, Mr. Newton has written me as follows:

January 21, 1919.

Mr. E. J. Prindle,
The Trinity Building,
111 Broadway,
New York, N. Y.

Dear Mr. Prindle:

Regarding the report of the Patent Committee, after careful consideration I have concluded it best to withdraw my approval of that part of the report concerning the separation of the Patent Office from the Interior Department.

I hope we will all exert ourselves for the passage of these statutes in proportion to the importance of the subject.

With best wishes, I am,
Sincerely,
(Signed) J. T. Newton,
Commissioner.

As Mr. Newton gives no reasons for this action, and as he does not state that he disapproves of this feature of the report, I infer that his action is taken because he considers that he cannot, with good grace, advocate a separation from the Interior Department while he is an official of that department.

Edwin J. Prindle.

January 23, 1919.

A Society pin was found some time ago in the railroad depot in Bridgeport, Conn., and forwarded to the New York headquarters of the Society, where it is being held awaiting the owner.

NECROLOGY

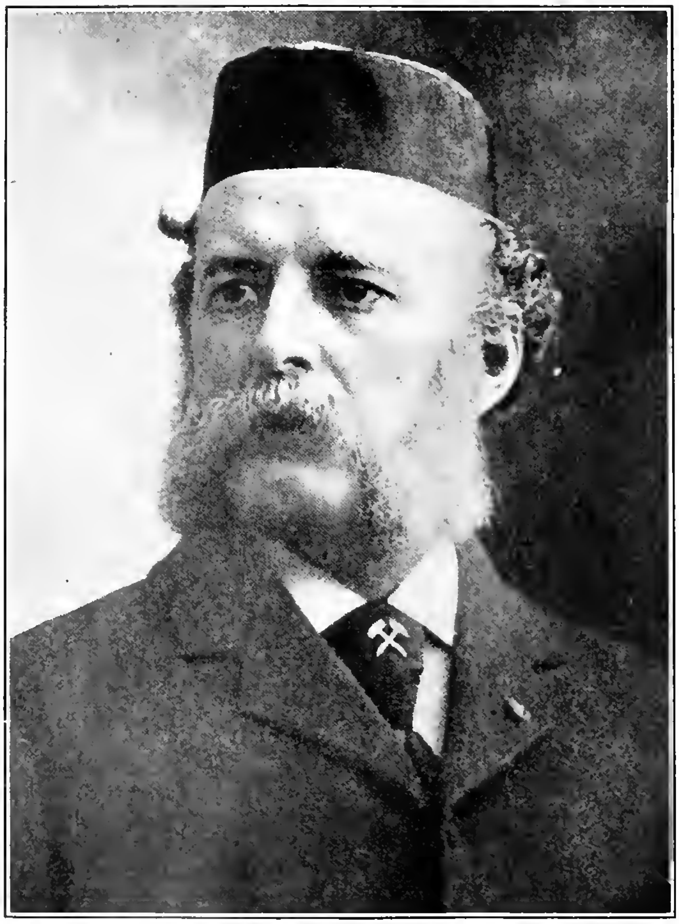
ROSSITER WORTHINGTON RAYMOND

Dr. Rossiter Worthington Raymond, mining engineer, metallurgist, lawyer and author, and for 25 years previous to 1912 the Secretary of the American Institute of Mining Engineers, died suddenly from heart trouble on December 31, at his home in Brooklyn, N. Y. He was born in Cincinnati, Ohio, April 27, 1840. He received his early education in the public schools of Syracuse, N. Y., and later attended the Brooklyn Polytechnic Institute, from which he graduated at the head of his class in 1858. He spent the ensuing three years in study at the Royal Mining Academy, Freiberg, Saxony, and at the Heidelberg and Munich Universities.

Returning to the United States in 1861, he entered the Federal Army and served as aide-de-camp, with the rank of captain, on the staff of Maj.-Gen. J. C. Fremont, by whom, during his campaign in the valley of Virginia, he was officially commended for gallant and meritorious conduct.

From 1864 to 1868 he engaged in practice as a consulting mining engineer and metallurgist in New York City, and in the latter year was appointed United States Commissioner of Mining Statistics, which position he held until 1876, issuing each year "Reports on the Mineral Resources of the United States West of the Rocky Mountains." In 1870 he was appointed lecturer on economic geology at Lafayette College, which chair he occupied until 1882. In 1873, Dr. Raymond was appointed United States Commissioner to the Vienna International Exposition, and as such delivered at Vienna addresses in the German language at the International Meeting of Geologists; and an address in English at the meeting of the Iron and Steel Institute at Liège, Belgium.

From 1875 to 1895 he was associated, as consulting engineer, with the firm of Cooper & Hewitt, owners of the New Jersey Steel & Iron Co., the Trenton Iron Co., the Durham and the Ringwood Iron Works, as well as numerous mines of iron ore and coal. As president of the Alliance Coal Co. and director of the Lehigh & Wilkes-Barre Coal Co., as well as a personal friend of Franklin B. Gowan, he became acquainted with the inner history of the memorable campaign against the "Molly Maguires," and has since been known as a fearless opponent of all tyranny practiced in the name of labor. His articles on "Labor and Law," "Labor and Liberty," etc., published in the *Engineering and Mining Journal* at the time of the Homestead riots, attracted wide attention, and for these, as well as similarly frank discussions of the operations of the Western Federation of Miners in Montana, Idaho and Colorado, he received special denunciations and threats from the labor unions thus criticised.



DR. ROSSITER W. RAYMOND

While connected with Cooper & Hewitt, he assisted Abram S. Hewitt in the management of Cooper Union and for many years directed the Saturday Evening Free Popular Lectures on Science, etc., which constituted the beginning of the present vast lecture system in New York City.

From 1885 to 1889, he was one of the three New York State Commissioners of Electric Subways for the City of Brooklyn, and served as member and secretary of the board. At the close of his official term as commissioner, he became consulting engineer to the New York & New Jersey Telephone Co.

In 1898, Dr. Raymond was admitted to the bar of the Supreme Court of New York State, and of the Federal District and Circuit Courts, his practice being confined to cases involving either mining or patent law, in the former of which he was a leading authority. In 1903, he was lecturer on mining law at Columbia University, New York.

He was an original member of the American Institute of Mining Engineers and served as its vice-president in 1871, 1876 and 1877; and as president from 1872 to 1875. While secretary of the Institute he edited the annual volumes of Transactions in a manner so painstaking and thorough, and with so high a degree of scholarship, that they were universally recognized as models of what such publications should be. To these he contributed many essays, especially pertaining to the United States mining laws, as well as other articles of importance. He was editor of the *American Journal of Mining* from 1867 to 1868, of the same periodical under the title *Engineering and Mining Journal* from 1868 to 1890, and continued thereafter a special contributor to that journal. In 1884 he prepared for the United States Geological Survey an historical sketch of mining law which was subsequently translated into German and published in full by the *Zeitschrift für Bergrecht*, the only periodical in the world devoted exclusively to the subject of mining jurisprudence.

In 1911, during the visit to Japan of a party of members and guests of the American Institute of Mining Engineers, Dr. Raymond received from the Mikado the distinction of Chevalier of the Order of the Rising Sun—fourth class, the highest ever given to foreigners not of royal blood—"for eminent services to the mining industry of Japan." These services consisted in advice and assistance rendered in America to Japanese engineers, students and officials throughout a period of more than twenty-five years.

In 1912, he resigned his position as secretary of the American Institute of Mining Engineers, of which he has been since that time secretary emeritus.

Dr. Raymond was an honorary member of the American Association for the Advancement of Science, the American Philosophical Society, the Society of Civil Engineers of France, the Iron and Steel Institute and the Institution of Mining and Metallurgy of Great Britain, the Canadian Mining Institute, the Mining Society of Nova Scotia, the Australasian Institute of Mining Engineers, and the Military Orders of the Loyal Legion of the United States; he as a member of the National Geographic Society, and a life member of the American Geographical Society. He received the degree of Ph.D. from Lafayette College in 1868, and that of LL.D. from Lehigh University in 1906 and from the University of Pittsburgh in 1915.

Besides the literary work already mentioned, Dr. Raymond prepared many other technical works and papers and was the author of a considerable number of books on general subjects, some in lighter vein and several of them for children. His writings to a remarkable degree were characterized by grace of expression, combined with clearness and unity, and his work bore ample evidence of the precision and accuracy of his scientific mind.

He married in Brooklyn, N. Y., March 3, 1863, Sarah Mellen Dwight of that city. He is survived by Mrs. Raymond and a daughter, Mrs. H. P. Bellinger of Syracuse, N. Y.

GAIL H. BROWNE

Gail H. Browne was born on March 12, 1871, in Salem, New York. He was educated in the public and high schools of Chicago, attending also the Chicago Medical College. He also spent two years in the Dental and Medical College of Northwestern University.

He spent the first five years after leaving college as surveyor and draftsman with the Chicago and North Western Railway and then with the International Harvester Co., and Swift & Co., at Chicago. In 1897 he became U. S. inspector of pier work and dredging in the Grand Rapids district. After one year in this district he became engineer in charge of the civil engineering department, McCormick division of the International Harvester Co. In 1905 he was employed by Ford, Bacon and Davis, engineers, New York. Since that time he has been actively engaged by this firm on important design and construction work, principally at Chicago, Memphis, New Orleans, Allentown, Pa. and in the New York office.

Mr. Browne died at his home in Glen Ridge, N. J., on December 7, 1918. He was a member of the Louisiana Engineering Society. He became a member of our Society in 1916.

ALFRED BETTS

Alfred Betts was born on October 1, 1835, in Wilmington, Del., and was educated at the Friends' School there. He served his apprenticeship with the firm of Pusey, Jones & Betts, Wilmington, afterwards becoming a member of the firm. He was a partner in the firm of E. & A. Betts, manufacturers of machine tools, and later became president of the Betts Machine Co., until his retirement in 1889. He was a member of the Board of Water Commissioners of Wilmington for six years.

Mr. Betts died on Dec. 1, 1918. He became a member of the Society in 1881.

PATRICK JOSEPH BEAKEY

Patrick J. Beakey was born in Glann, Ennistymon, County Clare, Ireland, on July 16, 1881, and was educated there in the Christian Brothers' School.

He came to the United States in 1900 and worked as a machinist for the P. & F. Corbin Co., New Britain, Conn., and for the Pratt & Whitney Co., Hartford, Conn. He was employed in 1903 by the Underwood Typewriter Co., also in Hartford, to build special machinery. In 1908 he joined the tool-making force of the Royal Typewriter Co. and was in a short time promoted to the foremanship of the type department. In this position he assisted in the development and production of typemaking machinery and tools, and designed and produced several styles of typewriter type. At the time of his death, Mr. Beakey was holding this position.

Patrick J. Beakey

Mr. Beakey died on October 24, 1918, of Spanish influenza. He became an associate member of the Society in 1915.

CHARLES MUNROE BURGESS

Charles M. Burgess was born in 1843 in Michigan. He served his apprenticeship with his father, a manufacturer of machinery in Windsor Locks, Conn. For about seven years he worked in the U. S. Armory at Springfield, Mass., and with the Collins Co., Collinsville, Conn., obtaining valuable shop experience. In 1866 he became associated with the Aetna Cutlery Works, New Britain, Conn., and about a year later entered the employ of Russell & Erwin as tool maker and was promoted shortly to foreman of the machine shops and in 1879 to the position of superintendent. In 1898 he retired from active business life.

Mr. Burgess was a member of Company C, 25th Regiment, Connecticut Volunteer Infantry, during the Civil War. He died on September 27, 1918. He became a life member of the Society in 1897.

Charles Munroe Burgess

MURRAY COPES CONLEY

Murray C. Conley was born on December 30, 1889, in Lamar, Mo., and was educated in the public schools of Wichita, Kan. He was graduated from the University of Kansas in 1909 and the following year took a post-graduate course in efficiency engineering.

His first position was with the Dewey Port Cement Co., Dewey, Okla., where he installed the cost sys'em, assisted in laying out and had charge of the construction of a pulverized-coal mill of 100 tons capacity. In September 1913 he became connected with the McEwen Manufacturing Co., Tulsa, Okla., where he assisted in the installation of the Taylor system of scientific management, later having charge of the design and testing on an experimental series of reversing gas engines. His next position was with the Carter Oil Co., Tulsa, where he was employed in laying out walls for tank forms. In Ocober, 1915, he became associated with the Pitcher Lead Co., Joplin, Mo., where he supervised the reconstruction of one of their small lead smelters and the construction of a new lead smelter at Galena, Kan. Later he had charge of the construction of a large zinc-ore smelter at Henryetta, Okla. In June, 1916, he took a position with the Henry L. Doherty Co., New York City, here he was employed in developing the process of pumping crude oils from the Kansas wells. Later he was assigned to one of the subsidiary companies, the Lorain County Electric Co. and was construction engineer on a large electric power plant at Lorain, Ohio, which position he held at the time of his death, December 21, 1918.

Mr. Conley became an associate member of the Society in 1917.

GEORGE DINKEL

George Dinkel, a member of the Society since 1890, was killed in an automobile accident near Havana, Cuba, on January 21.

Mr. Dinkel was born on November 28, 1866. He was graduated from Stevens Institute of Technology, Hoboken, N. J., in 1888, when he became associated with the American Sugar Refining Company as assistant manager at the Jersey City plant. At the time of his death he was chief engineer of the company, having been in its employ for 31 years.

He attained distinction in his profession, and was well known in the sugar industry. He had been granted a number of patents for important inventions, especially in the line of machinery for the refining of sugar.

Mr. Dinkel was also a member of the Engineers' Club of New York, and a member of the Board of Trustees of Stevens Institute of Technology.

FRANK CAZENOVE JONES

Frank C. Jones was born in Washington, D. C., on June 14, 1857. He was graduated from the University of Virginia and then attended Stevens Institute of Technology where he received his M. E. degree. His first two years upon graduation were spent with the Baldwin Locomotive Works. In 1879 he became connected with the Delaware Bridge Co., and was next employed as mechanical expert and superintendent of factories for the New York Belting & Packing Co. Somewhat later he became manager of the International Okonite Co. For a number of years he was also president of the W. A. Underhill Brick Co., New York. Mr. Jones organized the Manhattan Rubber Manufacturing Co. in 1893 and was president of this company for ten years at which time ill health compelled his retirement from active work. At the time of his death, September 19, 1918, he was a director of the Lubricating Oil Co., and chairman of the Okonite Co., New York. Mr. Jones became a member of the Society in 1891.

LIEUT.-COLONEL FRANK J. DUFFY

Frank J. Duffy, Lieutenant-Colonel, 103rd Engineers, U. S. Army, was killed in France on August 18, 1918. Colonel Duffy and motorcycle driver were travelling from one part of the American line to another in a motorcycle. A German shell struck alongside of the machine and both were killed.

Colonel Duffy was born on August 27, 1884, in Scranton, Pa., and was educated there. He served his apprenticeship with the Scranton Railway Co., and was then connected for a short period with a firm of electrical contractors in Scranton on telephone, signal work and motor installation in factories. In 1904 he entered the engineering department of the Bell Telephone Co., Scranton, and a year later took a position with the Delaware & Lackawanna Railroad Co., where he had charge of the electrical installation of the Keyser Valley car shops. From 1906 to 1909 he was in charge of the electrical department, Buffalo division, of the company, later being responsible for all the electrical work of the mining department, in Scranton, Pa.

Frank J. Duffy

When the United States entered the war Colonel Duffy was a leader in organizing the second company of engineers. He was named as Major and placed in charge of a battalion. While the 103rd regiment was in camp in Georgia Major Duffy was advanced to the rank of lieutenant-colonel.

Colonel Duffy was widely known in electrical circles throughout the country and was considered one of the foremost authorities in that industry. He was a member of the American Institute of Electrical Engineers, and of the Scranton Engineers' Club of which he was president. He became a member of our Society in 1917.

CLAUDE P. HAYNES

Claude P. Haynes was born in Ellsworth, Litchfield Co., Conn., on September 3, 1888. He attended the Rochester Mechanics' Institute for three years and later entered Syracuse University, taking the regular mechanical engineering course.

He served his apprenticeship as machinist with the General Electric Co., West Lynn, Mass., and was next with the American Optical Co., Southbridge, Mass., as draftsman. He held positions with the General Electric Co., Erie, Pa., where he designed the tools for a 175-hp. 8-cylinder gasoline motor; with the A. G. Gilman Printing Co., as chief engineer, designing two large rotary presses, folding and paper-handling machinery; with the Aetna Chemical Co., Pittsburgh, Pa., the Trantu Manufacturing Co., in the same city, as engineer salesman on power and power-transmission machinery; with the Aluminum Castings Co., Buffalo, N. Y., as chief engineer of their Niagara plant, and with the Curtiss Aeroplane & Motor Corporation as production engineer.

At the time of his death, Oct. 4, 1918, Mr. Haynes was holding the position of engineer in the research division of the Chemical Warfare Seervice in Washington, D. C.

Mr. Haynes became a junior member of the Society in 1916.

HENRY LOCKETT HUTSON

Henry Lockett Hutson was born at Americus, Ga., on December 30, 1876. He was the son of Charles Woodward Hutson and his wife, Mary Jane Lockett. His father was a college professor, occupying chairs in various southern colleges, including the University of Mississippi at Oxford, and the A. & M. College of Texas at Bryan.

Mr. Hutson received his preliminary education in the public and private schools in the towns where his family resided, and his college training at the A. & M. College of Texas, where he was graduated in the mechanical engineering course in 1896, one of the first three in his class. He exhibited unusual talent for mechanical work in his early childhood, and was a great student of engineering subjects up to the time of his death.

In 1898 he volunteered as a private in the First Regiment of the U. S. Volunteer Infantry, commanded by Colonel Riche. In 1898, after being mustered out, he entered the employ of Henry R. Worthington at the Brooklyn shops as a student apprentice and received the usual thorough training in practical hydraulic engineering given by the Worthington Company. In 1901 he entered the employ of A. M. Lockett & Co., Ltd., of New Orleans, as mechanical engineer. By reason of his ability and great loyalty to the interests of the company he was later promoted to the position of chief engineer.

In addition to engineering skill he possessed unusual talent in business management, and in addition to his work as chief engineer he was the sales manager and secretary of the Lockett Company. He supervised the designing and construction of perhaps a greater number of low-lift centrifugal pumping plants of large capacity than any other one engineer in this country, and by reason of this broad experience he was regarded as an authority on this class of work by other engineers in the Southwest.

Henry L. Huston

Mr. Hutson became a member of the Society in 1906 and at the time of his death was Chairman of the New Orleans Section. He was also an active member of the Louisiana Engineering Society. He died on January 10, 1919.

OCTAVIUS AUGUSTUS LAW

Octavius A. Law was born on October 27, 1872, in Philadelphia, Pa., and received his education in the public schools of that city. He served his apprenticeship with William B. Smith, a general contractor of Philadelphia, later becoming his estimator, draftsman and foreman of erection of numerous public buildings. In 1899 he became connected with the Midvale Steel Co., Philadelphia, as assistant to the chief engineer and had entire charge of all furnace and building construction. He was with this company at the time of his death, October 26, 1918.

Mr. Law became an associate of the Society in 1915.

LEO JULIUS LEFFLER

Leo J. Leffler was born on June 30, 1885, in New York City. He was educated in the public schools of Brooklyn, attending Manual Training High School and later Cornell University from which he was graduated in 1907 with the degree of M. E.

Upon graduation he entered the corporation of Chas. Leffler & Co., Brooklyn, manufacturers of machinery and dies for the manufacture of tin and sheet-metal ware. He assisted his father, Mr. Charles Leffler in the active management of the company. He was secretary of the firm and was holding this position at the time of his death.

Mr. Leffler died on December 20, 1918, in Albuquerque, N. M. He became an associate-member of the Society in 1915.

FRANK SHEPPARD LEISENRING

Frank S. Leisenring was born on January 18, 1887, in Northumberland, Pa. His family moved to Harrisburg, Pa., where he attended the public schools and later the Bordentown Military Academy, where he finished his preparation for Stevens Institute of Technology at the Stevens School, graduating from the latter in 1904. He then entered Stevens and was graduated with the class of 1908.

Upon graduation he entered the employ of the J. F. Shanley Co., contractors, Newark, N. J., and finally became their superintendent. He later went into the railroad supply business for himself under the name of the Mechanical Specialties Co., New York, holding the position of president. For five months after we entered the war he was engaged in inspecting wire for the Government at New Haven, Conn. The last year he devoted to engineering activities in the manufacture of airplanes for the United States Government.

In the latter part of 1917 Mr. Leisenring joined the 22d Regiment, New York State Guard, Company F. He later left Company F and organized a company of engineers, known as Company M, 22d Regiment, New York State Guard, and was connected with this company as Second Lieutenant.

Mr. Leisenring died on October 23, 1918, of pneumonia. He became an associate-member of the Society in 1917.

STEPHEN MINOT PITMAN

Stephen M. Pitman, vice-president of the Narragansett Mutual Fire Inurance Co., died at his home in Providence, R. I., on December 17, 1918.

Mr. Pitman was born in Boston, Mass., on July 19, 1850, and was educated in the public schools of that city. For a short period he attended Brown University, later going to Tufts College, where he received the degree of Ph. B. in 1869. Following his graduation from Tufts Mr. Pitman entered the Harvard School of Mining, receiving the degree of Mining Engineer in 1874, and afterwards went to Germany, where he pursued special studies in chemistry at the Universities of Heidelberg and Berlin. From 1877 to 1882 he was professor of chemistry at Tufts, at the close of that time becoming treasurer and general manager of the Butte Silver & Mining Copper Co., Butte, Mont. In 1886 he returned East as chemist and superintendent of the Valley Falls Co., Valley Falls, R. I. In 1888 he became general manager of the Copp Dyeing Co. He later became secretary of the Philadelphia Manufacturers' Mutual Fire Insurance Co., and was for a time connected with the Holmes Fibre Graphite Co., also of Philadelphia.

In 1894 he was elected secretary-treasurer of the Narragansett Mutual Fire Insurance Co., Providence, R. I., and remained in that capacity until he became vice-president, the office he was holding at the time of his death. He was also a director of the American Investment Co.

Mr. Pitman became an associate of the Society in 1892.

GEOFFREY LAWRENCE REID

Geoffrey L. Reid was born in Lawrence, Mass., on March 29, 1894. He was educated in the public schools of Lawrence and upon graduation from high school entered Massachusetts Institute of Technology, from which he was graduated in 1916 as a mechanical engineer.

His first position was with the General Electric Co., Lynn, Mass., in connection with cost work and estimating on Curtis steam turbines. He was next employed in the inspection department of the Associated Factory Mutual Co's., Boston, leaving that firm to enter the statistical department of the Stone & Webster Engineering Corporation, Boston. In December, 1917, he enlisted in the U. S. Naval Aviation Corps and was assigned as an inspector of aeroplane motors and stationed at the Curtiss Aeroplane & Motor Corporation, Buffalo, N. Y. In April, 1918, he received his honorable discharge from the Army owing to ill health.

Mr. Reid died on December 23, 1918. He became a junior member of the Society in 1916.

EDWIN H. ROUSSEAU

Edwin H. Rousseau was born in New Orleans, La., in September, 1884. He was graduated from the Louisiana State University in 1905 with the degrees of B. S. and M. E. He also attended Tulane University.

His first position was with the Central Electric & Improvement Co., Inc., New Orleans, where he was located for about four years. In 1910 he became manager of the order department and draftsman for the John H. Murphy Iron Works, also in New Orleans. Three years later Mr. Rousseau became connected with Dibert, Bancroft & Ross Co., Ltd., as a designer on multiple-effect evaporators, vacuum pans and barometric condensers, resigning in 1916 to take a position with the Dyer Co., Cleveland, Ohio, having charge of the cane-sugar department, handling all engineering incidental to building cane-sugar factories, etc. In the early part of 1917 Mr. Rousseau became assistant engineer in the engineering department of the E. B. Badger & Sons Co., Boston, Mass., where he had charge of the engineering work connected with the building of complete industrial and chemical plants.

Since October, 1917, Mr. Rousseau has been with the Birmingham Machine & Foundry Co., Birmingham, Ala., as chief engineer, which position he was holding at the time of his death, December 3, 1918.

Mr. Rousseau became a member of the Society in 1915. He was also a member of the Chemists' Club of New York and of the Civic Association of Birmingham.

ANGUS SINCLAIR

Angus Sinclair, D. E., founder and for the last 32 years editor-in-chief of *Railway and Locomotive Engineering*, died January 1, 1919,

Angus Sinclair

at his home in Milburn, N. J. He was born at Forfar, Scotland, and began his railroad career as a telegraph operator, gaining his engineering knowledge at the shops of the Scottish Northeastern Railway at Arbroath. After some service as a marine engineer he came to America and again took up railroading, first with the Erie and later as a locomotive engineer on the Burlington, Cedar Rapids and Northern. He attended the chemistry classes of the Iowa State University and was later appointed chemist on the railway, combined with the duties of roundhouse foreman. It was during this period that he first gave serious attention to the problem of fuel economy and smoke prevention. His methods, which met with considerable opposition at first, are now universally approved.

In 1883 he joined the editorial staff of the *American Machinist* and later became proprietor and editor of *Railway and Locomotive Engineering*. In a short time this paper became a leading authority in its field and has maintained its high character and standing ever since. Dr. Sinclair was the author of many popular books on engineering subjects. In 1908 he received the honorary degree of Doctor of Engineering from Purdue University. About this time he was also appointed special technical instructor in the mechanical department of the Erie Railroad. He traveled extensively in Europe as well as in America and was everywhere received as among the foremost authorities on all matters connected with the mechanical department of railways. He was closely identified with the work of many of the leading engineering societies in America and in Europe. He was elected a member of the American Railway Master Mechanics' Association in 1873. He served as secretary of the association from 1887 to 1896, was elected treasurer in 1900 and served continuously until the time of his death. He became a member of the Master Car Builders' Association in 1873. He was the first president of the New Jersey Automobile and Motor Club. He was a delegate to the International Railway Congress, held at Washington, D. C., St. Louis, Mo., and Berne, Switzerland.

Among the societies which he aided in establishing was the Traveling Engineers' Association, founded in his office in 1892. He was a Knight Templar in the Masonic fraternity, a governor in the St. Andrew's Society, ex-president of the Burns Society, besides being a member of the American Railway Guild, Lawyers' Club, New York Railway Club and numerous railway, Scottish and other societies.

Dr. Sinclair became a member of our Society in 1883.

CLARENCE B. D. UNVERFERTH

Clarence B. D. Unverferth was born on October 10, 1884, in Dayton, Ohio. He was educated in the parochial schools and in St. Mary's

College in Dayton, later taking a special course in hydraulic and steam engineering.

From 1902 to 1907 he was connected with the Platt Iron Works, Dayton, as draftsman on pumps, heaters, condensers and filter-press machinery. His next position was with the Dayton Hydraulic Machinery Co., as chief draftsman and designer on centrifugal pumps. He was with this company for three years, resigning to become designer and draftsman on paper-mill machinery and water wheels for the Dayton Globe Iron Works. In 1911 he became connected with the Ohmer Fare Register Co., Dayton, as tool designer, and the following year was with the Recording and Computing Machines Co., Dayton, as designer of tools and screw-machine cams. In 1913 he entered the office of the County Engineer of Montgomery County, Ohio, as chief draftsman and surveyor in charge of all drafting and field work. At the time of his death he was connected with the Aircraft Production Board at Dayton.

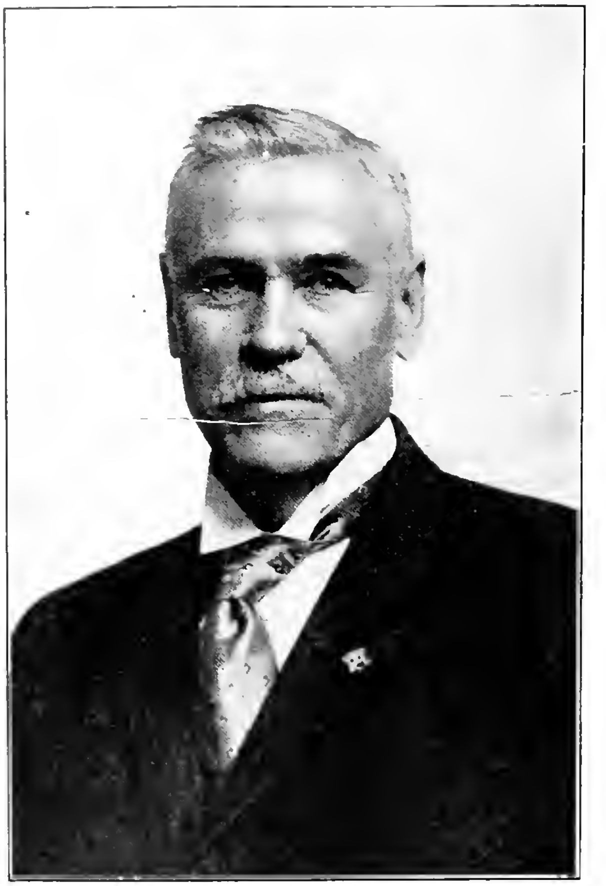
Mr. Unverferth died of pneumonia on November 10, 1918. He became an associate-member of our Society in 1918.

ROLLA C. CARPENTER

Prof. Rolla C. Carpenter, who has been a prominent member of the faculty of Sibley College, Cornell University, since 1890, died at his home at Ithaca, N. Y., on January 19.

The following account of Professor Carpenter's life is taken from that prepared only a few months ago for the *Sibley Journal of Engineering* at the time when he was about to retire from active service at the University, to devote his attention to engineering and consulting work, particularly along the lines of coke manufacture and the recovery of by-products incident to that industry. For many years Professor Carpenter was one of the most actively participating members of The American Society of Mechanical Engineers, a frequent attendant at meetings and one whom a very large number who came to the meetings always wanted to see and talk with.

Professor Carpenter was born near Orion, Michigan, June 26, 1852. His father, Charles K. Carpenter, owned an extensive farm at this place and was also vice-president of a railroad running between Detroit and Bay City, which now forms part of the Michigan Central system.



Rolla C. Carpenter

He graduated from Michigan Agricultural College in 1873 and received the degree of Civil Engineer from the University of Michigan in 1875. He was then engaged as an instructor in the Michigan Agricultural College, at the same time doing graduate work, and received the degree of Master of Science in 1876. In 1878 he was elected professor of mathematics and civil engineering at the Michigan Agricultural College, which position he held until 1890. During part of this period he spent his vacations, which then came in the winter months, studying at other institutions. Part of this time was spent at the Massachusetts Institute of Technology, where he studied under Professors Peabody and Lanza, and part was spent at Cornell, where he received the degree of Master of Mechanical Engineering in 1888. He was greatly assisted in the preparation of his thesis for the M.M.E. degree by his connection with the Lansing Iron and Engine Company of Lansing, Michigan, as consulting engineer. This connection placed at his disposal the facilities of a large and up-to-date manufacturing plant which offered opportunities not then enjoyed by any of the technical schools. This thesis, which is now on file in the University library and which was reported upon by Dr. Thurston in a paper read before The American Society of Mechanical Engineers, was on the subject of Internal Friction in Non-Condensing Engines and, as shown by Dr. Thurston's discussion, played an important part in the entire revision of the ideas which then prevailed concerning steam-engine friction.

In 1890 Professor Carpenter was elected Associate Professor of Engineering at Cornell University and the laboratory work was organized as a separate department under his direction. In 1895 he was elected professor of experimental engineering, which position he held up to the time of his death.

Professor Carpenter's experience in the several leading educational institutions as well as his intimate contact with various industrial enterprises peculiarly fitted him for the work of building up a course of instruction in experimental engineering which has done much for the upbuilding of the reputation of Sibley College and which is regarded by many alumni as furnishing a most valuable part of their education.

This system has been copied with some modifications in many other colleges and technical schools and has no doubt had a pronounced influence upon the methods of teaching other sciences.

Professor Carpenter published his "Notes on Mechanical Laboratory Practice" in 1891. This was the basis of his later text book on "Experimental Engineering" which has been the leading manual in this country on the subject. The first edition of his book on heating and ventilation was published in 1895 entitled "Heating and Ventilating Buildings." This book has gone through six revisions and has had an extensive circulation. It contains much original material from the author's own experience and is much quoted by later writers on heating and ventilating. Professor Carpenter is also joint author with Professor Diederichs of a textbook on "Gas Engines." In addition to these books, he has made many contributions to engineering literature through various societies and publications, among which may be mentioned The American Society of Mechanical Engineers, the American Society of Civil Engineers, and the American Society of Heating and Ventilating Engineers.

Professor Carpenter held membership in eight of the leading engineering societies of America. He was vice-president of The American Society of Mechanical Engineers from 1908 to 1911 and served on various committees of this Society, perhaps the most important of which is the Boiler Code Committee. He was President of the American Society of Heating and Ventilating Engineers in 1898, was vice-president of the American Society of Automobile Engineers in 1910-12, and has taken an active interest in the student branch of The American Society of Mechanical Engineers at Cornell.

Professor Carpenter engaged in a diversified field of investigation and research, including problems relating to power plants, gas engines, cement manufacture, coke manufacture, railway management, heating and ventilating, etc. He was one of the leading patent experts in the country and was employed by many of the leading law firms in various parts of the United States. He invented a number of pieces of laboratory apparatus, such as the Carpenter coal calorimeter, which was for many years a standard for testing the heating value of coal, the throttling and separating steam calorimeters now extensively used, a friction testing machine which may be found in most of the large laboratories and an inertia governor for the steam engine.

Professor Carpenter was honored by appointment to various positions of distinction. He was judge of machinery and transportation at the Chicago Exposition in 1893, at the Buffalo Exposition in 1901, and at the Jamestown Exposition in 1907. He was a member of the commission appointed by the Academy of Science in 1915 at the request of the President of the United States to investigate the slides at the Panama Canal and to make such recommendations as in the judgment of the commission would improve the conditions and lessen the possibilities of slides in the future. He received the degree of Doctor of Laws in 1907 from the Michigan Agricultural College.

Professor Carpenter's kindly manner and genial disposition made it easy for even the most timid to approach him and he was never too busy to be considerate of anyone who sought his council and advice. His large and varied experience, coupled with good judgment and his extensive knowledge of the engineering profession and of human nature, made his counsel and advice exceedingly valuable to his colleagues as well as to students and the world at large.

In a pamphlet on International Control of Minerals recently issued by the U. S. Geological Survey, the strategic position of the United States is graphically shown by a table compiled by Dr. C. K. Leith. The United States controls about one-third of the world's mineral production of 1,700,000,000 tons. The few minerals for which this country is dependent on foreign countries are offset by so many in which we have a dominance of supply and our financial position is so strong that it appears certain that in this respect our entrance into a league of nations would not be based on self-interest. The interests of conservation clearly require an international control of minerals. But this will depend on whether the nations are willing to make the necessary economic sacrifices in the interest of world harmony.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by February 15 in order to appear in the March issue.

CHANGES OF POSITION

Alexander M. Grier has become associated with the Combahee Company, White Hall, S. C., in the capacity of general manager. He was formerly sanitary engineer with the E. I. duPont de Nemours and Company, Wilmington, Del.

Arthur B. Coates has resigned his position with the Ford Motor Company, Detroit, Mich., in the power and construction department, and has accepted the position of assistant mechanical engineer with the U. S. Bureau of Mines, Pittsburgh, Pa.

Paul Been has become affiliated with the Morgan Engineering Company, Alliance, Ohio, in the capacity of engineer. He was until recently connected with the Manierre Engineering and Machine Company, Milwaukee, Wis.

Leon E. Jeanneret, formerly connected with the Babcock and Wilcox Company, Bayonne, N. J., has become associated with the King Bridge Company, Cleveland, Ohio.

B. R. Sausen, formerly manager of the Chicago office of the Schutte and Koerting Company, has become identified with the Star Brass Works of the same city, engaged in sales promotion and research work of Spray cooling equipment.

Frederick A. Scheffler, formerly connected with the New York offices of the Babcock and Wilcox Company, has become associated with the Fuller Engineering Company, of Allentown, Pa., as manager of the department devoted to the application and introduction of pulverized coal equipment for steam power plants in the United States. Mr. Scheffler's headquarters are in New York City.

Ernest K. Hill, until recently connected with the Wright-Martin Aircraft Corporation, New Brunswick, N. J., in the capacity of assembly inspector has assumed the position of mechanical draftsman with the E. J. Longyear Company, Marquette, Mich.

W. Jocelyn Dale has resigned as superintendent of power for the Matahambre Copper Mines at Sta Lucia, Pinar del Rio, Cuba, to take the position of electrical engineer with the Elia Sugar Company, and engineer with the Cuba Cane Sugar Corporation, of Havana, Cuba.

Ray Mayhew has severed his connections with the Minneapolis Steel and Machinery Company, Minneapolis, Minn., with whom he has been affiliated for ten years, and has accepted a position as motor engineer with the American Hoist and Derrick Company, St. Paul, Minn.

Roy A. Watkins is no longer connected with the Bureau of Steam Engineering at Washington, D. C., having assumed the duties of vice-president and general manager of the Bath Machine Works, Inc., Bath, N. Y.

ANNOUNCEMENTS

N. L. Snow, formerly vice-president and sales manager of the Terry Steam Turbine Company, Hartford, Conn., has been elected vice-president and general manager of that company. Mr. Snow has been connected with the company for the past ten years.

William Paterson has accepted a position with the Illinois Maintenance Company, Chicago, Ill.

Louis W. Adams has assumed the position of manager of the open hearth department of the Ashland Iron and Mining Company, Ashland, Ky.

Henry Ford has resigned the presidency of the Ford Motor Company, Detroit, Mich., to devote his time to his new weekly newspaper, the *Dearborn Independent*, and his tractor plant at Dearborn, Mich.

Frank D. Baker, formerly in mechanical and mill design in Colorado and, since its organization in 1899, with the American Smelting and Refining Company, as chief engineer of the Colorado department, has retired. He will do limited mechanical consultant work in Denver, in association with his sons.

Walter N. Polakov, consulting engineer, announces the founding of Walter N. Polakov and Company, Inc., New York, consultants in power-production methods, industrial investigations, labor problems, scientific-record systems and production accounting.

Alfred Musso will have charge of the Coast Coaling and Engineering Company's newly-organized department for the development of labor-saving machinery. He will give special attention to questions pertaining to the handling of bulky materials, the coaling of ships and general stevedoring.

Herbert B. Reynolds, formerly a fuel engineer in the U. S. Bureau of Mines, has returned to the motive power department of the Interborough Rapid Transit Company, of New York, as mechanical research engineer.

Morris L. Cooke, Boyd Fisher, Keppele Hall, Horace K. Hathaway, Clyde L. King and John H. Williams, announce the opening of an office in Philadelphia, Pa., as consulting engineers in management.

M. L. Kaufman is a member of the recently established firm of Kaufman and Levine, consulting and industrial engineers, of New York. Mr. Kaufman was employed, for the last three and a half years, by J. H. Wallace and Company, pulp and paper engineers; recently, he was engineer on a section of the work at Nitro, W. Va., connected with the Cotton Purification Area, U. S. Explosives Plant "C."

Lieut-Commander Frederick L. Pryor was presented, on December 21, with a gold watch by the released students at the demobilization of the Naval Section of the Students' Army Training Corps at Stevens Institute of Technology, Hoboken, N. J.

James W. Smith resigned, on January 1, as general superintendent of Gray and Davis, Inc., Cambridge, Mass.

Cleland Coldwell Ross, formerly superintendent with the Coldwell Lawn Mower Company, of Newburgh, N. Y., has recently returned to that company as works manager after serving as a lieutenant in the Ordnance Department of the Army.

Charles T. Myers, formerly production engineer of the Savage Arms Corporation, Utica, N. Y., has been appointed works engineer of the Utica plant, in complete charge of the operation and maintenance of the mechanical and electrical departments of the plant.

Robert E. Newcomb, superintendent of the Deane Works of the Worthington Pump and Machinery Corporation, Holyoke, Mass., was elected president of the New England Foundrymen's Association, at a meeting held in Boston, January 8.

George E. Randles, general manager of the Foote-Burt Company, Cleveland, Ohio, has resigned as director of the maintenance division of the Motor Transport Corps and has returned to his regular duties in Cleveland, from Washington, where he has been located for more than a year.

APPOINTMENTS

Melvin B. Newcomb, formerly chief draftsman of the hydraulic department of the Wellman Seaver Morgan Company, Cleveland, Ohio, has been appointed chief engineer of the rubber machinery department at the Akron, Ohio, works of the same company.

LIBRARY NOTES AND BOOK REVIEWS

George Westinghouse

George Westinghouse. His Life and Achievements. By Francis E. Leupp. Little, Brown and Co., Boston, 1918. Cloth, 6 x 9 in., 304 pp., 5 pl., 6 portraits. $3.

George Westinghouse was a prominent figure in the industrial life not only of America, but of the world for so many years, that it was greatly to be desired that a suitable biography should be written for the satisfaction of his friends and admirers and for the instruction of the younger men in the industrial field.

He worked in so many lines, and with such splendid results, that a complete biography would cover the engineering and technical work which he did, as well as the administrative and business side of his career.

Mr. Leupp is an accomplished literary man, but not an engineer; and he undoubtedly felt that he could not with advantage discuss the technical side of Mr. Westinghouse's career. He disarms criticism by confessing frankly that the mission of his volume is simply human. It is a pleasure to say that within its limitations this biography of Mr. Westinghouse is quite complete and satisfactory. Indeed, it is a credit to Mr. Leupp's industry and investigation that he should have been able, with practically nothing in the shape of diaries or personal correspondence, and relying for the personal touch almost entirely on the memory of associates, to give such a true picture of the great and wonderful man about whom he was writing.

There are, of course, omissions which will occur to anyone who was at all intimate with Mr. Westinghouse and his interests, such, for example, as the absence of the name of Benjamin G. Lamme from the list of able assistants in the electrical field. By many he is regarded as the most striking figure, in the way of electrical genius, of these assistants.

Mr. Leupp stresses the well-known fact among his intimates of Mr. Westinghouse's great confidence in his own judgment;

but it is not quite so clear as he might have made it that there was great justification for this confidence from the numerous cases in which Mr. Westinghouse had backed his own judgment against that of his advisors, and had proved to be right. The reviewer makes this remark because he once had occasion to discuss this very point with a critic of Mr. Westinghouse; and after explaining in detail a number of important and remarkable cases where his judgment had been proved correct, the critic agreed that it was not a cause for surprise that he should have trusted his own judgment more than that of any other person.

The financial difficulties through which the Electric Company passed led many careless observers to say that Mr. Westinghouse was no financier. Mr. Leupp tells the story of the difficulties, both in 1893 and 1907, and shews, to those who know, his appreciation of the fact that Mr. Westinghouse really was a great financier. It so happens that the reviewer, who was then an officer of the Electric Company, came into possession of information entirely independent of Mr. Westinghouse, through financial friends in Pittsburgh, which showed that the rehabilitation of the Electric Company in 1908 was due entirely to Mr. Westinghouse. The Committee of Bankers had advised a scheme which fell absolutely flat; and it was not until the so-called Merchandise-Creditors Plan was proposed that any success was attained. This plan was, in conception and detail, the work of Mr. Westinghouse. Doubtless this is a case of definition. If to be a financier means to sit in a marble palace, handling other people's money and making loans with ample security, refusing absolutely to take any chances whatever, then doubtless Mr. Westinghouse would not have laid any claim to being a financier. If, on the contrary, the courageous meeting of unusual difficulties with all the usually recognized financial authorities against you and success in the solution of the difficulties, is to be a financier, then he certainly was a great one.

It is a pleasure to note in Mr. Leupp's book that Mrs. Westinghouse receives considerable notice; and he shows her great executive ability as a hostess in the sympathetic story he tells. If he had known her intimately, he might have given additional touches showing her great sympathy and attention to all her guests, even the humblest; a trait which does not always accompany the executive capacity.

Mr. Leupp was evidently thoroughly in sympathy with, and a great admirer of, the wonderful man about whom he wrote, a condition which the writer believes absolutely necessary to a satisfactory biography; and the book can be confidently recommended to all who admire the story of a great life, full of wonderful deeds, and a benefit to humanity. As already stated, it is by no means a complete biography, because only the outstanding facts about his great works are given; and the engineering and technical side is almost entirely absent. It is to be hoped that before long the biography will be written by some competent engineer who is also an accomplished literary man, so that the complete story of the wonderful life of George Westinghouse may be preserved.

W. M. MCFARLAND.

THE A-B-C OF AVIATION. A complete, practical Treatise outlining clearly the Elements of Aeronautical Engineering with special reference to simplified Explanations of the Theory of Flight, Aerodynamics and Basic Principles underlying the Action of Balloons and Airplanes of all Types. A non-technical Manual for all Students of Aircraft. This book includes instructions for lining up and inspecting typical Airplanes before flight and also gives easily understood rules for flying. By Victor W. Page. The Norman W. Henley Publishing Co., New York, 1918. Cloth, 6 x 9 in., 274 pp., 128 illus., 7 pl. $2.50.

A companion volume to the author's Aviation Engines, giving a simple account of the operation and repair of airplanes. Intended for use by prospective aviators and mechanics, not as a treatise for engineers and designers.

AEROBATICS. By H. Barber. Robert M. McBride and Co., New York, 1918. Cloth, 11 x 18 in., 61 pp., 29 pl. $3.

An explanation of the general rules governing flying. The instruction is arranged in progressive form and is intended to convert the novice into an expert pilot in the shortest possible time, with the greatest possible degree of safety to himself and his machine.

AMERICAN ENGINEERS BEHIND THE BATTLE LINES IN FRANCE. By Robert K. Tomlin, Jr. First edition. N. Y., published by *Engineering News-Record*. (McGraw-Hill Book Co., Inc., sole selling agents.) New York, 1918. ¼ cloth, 9 x 12 in., 91 pp., illus. $2.

These nineteen articles, reprinted from the McGraw-Hill periodicals of the year, describe various phases of the engineering work executed by the American Army. Gathered together, they form an interesting account of the problems and the methods used to solve them.

AMERICAN PROBLEMS OF RECONSTRUCTION. A National Symposium on the Economic and Financial Aspects. Edited by Elisha M. Friedman, with a Foreword by Franklin K. Lane. E. P. Dutton and Co., New York, 1918. Cloth, 5 x 8 in., 471 pp. $5.

The editor here presents the opinions of some twenty-eight prominent Americans in the hope of stimulating thought on the subject. The specific points treated are the temporary effects of the war, the best methods of facilitating our readjustment to peace conditions, the permanent effects of the war, the changes that these will effect in our national life, and the national economic policy that should be adopted.

ANNUAL CHEMICAL DIRECTORY OF THE UNITED STATES. Second edition, 1918. Consulting Editor, B. F. Lovelace; Managing Editor, Charles C. Thomas. Williams and Wilkins Co., Baltimore. (copyright 1918). Cloth, 6 x 9 in., 534 pp. $5.

This directory is intended as a comprehensive review of all matters relating to industrial, technical and scientific chemical development in the United States. It contains lists, classified by subject and location, of manufacturers and dealers in chemicals and allied products and in equipment; a geographical directory of industrial, institutional, federal, state, municipal and commercial laboratories; a list of technical and scientific societies of the world, and bibliographies of technical and scientific journals, and of the important new books of 1917-1918. A "News and Notes" section completes the work. This second issue is approximately twice as large as the first.

THE ATOMIC WEIGHTS OF BORON AND FLUORINE. By Edgar F. Smith and Walter K. Van Haagen. Carnegie Institution, Washington, D. C. Paper, 7 x 10 in., 65 pp., 4 illus., 4 tab. $1.

The authors decribe in detail their work upon the atomic weight of boron and give a recalculation of that of fluorine, based upon their new value for boron. This latter value is considerably lower than that hitherto accepted.

ELECTRIC MOTORS AND CONTROL SYSTEMS. A Treatise on Electric Traction Motors and Their Control. By A. T. Dover. Sir Isaac Pitman and Sons, Ltd., London, 1918. Cloth, 6 x 9 in., 372 pp., 315 illus., 9 tab. $6.

In this volume, which is an amplification of a portion of his work on Electric Traction, the author treats of the application of electric motors to railways. The endeavor has been to meet the needs of engineers and advanced students of engineering, rather than those of specialists in electric railway equipment.

ELECTRICAL EQUIPMENT OF THE MOTOR CAR. By David Penn Moreton and Darwin S. Hatch. U. P. C. Book Co., Inc., New York, 1918. Flexible cloth, 5 x 7 in., 506 pp., 428 illus. $2.50.

This work is intended to give the lay reader sufficient knowledge of the electrical equipment of an automobile to enable him to operate it intelligently and to make ordinary adjustments and repairs. It is compiled from a series of articles that appeared in *Motor Age*, with additions and emendations.

ELECTRICITY AND MAGNETISM FOR ENGINEERS. Part I. Electric and Magnetic Circuits. By Harold Pender. First edition. McGraw-Hill Book Co., Inc., New York, 1918. Cloth, 6 x 9 in., 380 pp., 98 illus. $3.

This volume covers substantially the same ground as that of the author's Principles of Electrical Engineering. The method of treatment, however, is distinctly different. The various laws and relations are more fully discussed and a greater number of practical applications are given. Particular emphasis is laid upon exact quantitative statements of the fundamental laws.

THE ENGINEERING INDEX

Published Monthly by The American Society of Mechanical Engineers

The Engineering Index was Founded in 1884 by the Association of Engineering Societies; Published from 1895 to 1918, inclusive, by The Engineering Magazine Company; and Acquired January 1919 by The American Society of Mechanical Engineers

THE following pages form a descriptive Index to articles on engineering and related subjects in current periodicals. In its preparation the Society's engineering staff regularly examines all of the technical journals and society publications received by the Engineering Societies Library, which form one of the greatest and most complete collections of scientific periodicals in the world, comprising upward of 1100 distinct publications in some ten languages. Cross-references are freely introduced in the Index, and in all cases where the titles of articles are not sufficiently descriptive, explanatory sentences are appended. The main abbreviations used in the items are given at the bottom of this page.

PHOTOSTATIC COPIES OF ARTICLES LISTED

THE Society is prepared to supply photostatic copies (white printing on brown background) of any of the articles listed. Copies of the periodicals themselves, or clippings of articles, cannot be supplied.

Price of each print (up to 11 x 14 in. in size), 25 cents plus postage. A separate print is required for each page of the larger-size periodicals, but where possible two pages will be photographed together on the same print. Bill will be mailed with the prints.

Those holding coupon books for clippings formerly issued by The Engineering Magazine Company may use the coupons in payment for photostatic prints. In ordering, state plainly

(1) Page number of Index on which item appears
(2) Title of article
(3) Name of periodical.

Orders should be sent to

Harrison W. Craver, *Director*,
Engineering Societies Library,
29 West 39th Street, New York City.

DIVISIONS OF THE ENGINEERING INDEX

Mechanical Engineering

AIR MACHINERY

Turbo-Blowers

Coppus Turbo Blower. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 74-75, 2 figs. Mechanical features of machine constructed by Coppus Eng. & Equipment Co.

Combined Motor and Turbine Driven Blast-Furnace Blower. Iron & Coal Trades Rev., vol. 47, no. 2645, Nov. 8, 1918, p. 523, 1 fig. Operation of unit consisting of synchronous motor driving blower, this motor being operated in addition as a power-factor adjuster on a 3000-volt 50-cycle supply.

Ventilators

The Largest Round Ventilator in the World. Metal Worker, vol. 91, no. 1, Jan. 3, 1919, pp. 28-29, 3 figs. Details of special construction to withstand wind pressure and secure permanence and service.

CORROSION

Aircraft Parts

Corrosion Prevention on Aircraft Metal Parts, H. A. Gardner. Aviation, vol. 5, no. 9, Dec. 1, 1918, pp. 565. Quotes standard procedure of Navy Department for protection or iron, steel and aluminum aircraft parts.

Pipe

Investigation of Pipe Corrosion in Chicago Buildings, with Special Reference to Durability of Pipe Materials, Thomas J. Claffy. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 208-210. Data secured from inspection of 63 buildings. Rating of cast iron, wrought iron and steel.

FORGING

Density of Steel

Does Forging Increase Specific Density of Steel? H. E. Doerr. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 79-81, 2 figs. Table of specific densities of ten ingots of basic open-hearth steel both before and after forging shows little or no change in density with steel initially free from cavities.

Drop Forging

Drop Forging in Automobile and Aircraft Work. Part VI. Automobile Engr., vol. 8, no. 120, Nov. 1918, pp. 328-331, 13 figs. Details of typical plant, with description of modern tools and methods.

Gun Forgings

Making Gun Forgings Under War Demands, E. C. Kreutzberg. Iron Trade Rev., vol. 63, no 22, Nov. 28, 1918, pp. 1240-1242, 6 figs. General character of work done by Tacony Ordnance Corps., Philadelphia.

Operation

Recommendations for Economical Operation of Iron Works (Dispositions générales qui peuvent être recommandées dans les installations de forges), O. Duperron. Génie Civil, vol. 73, nos. 20 and 21, Nov. 16 and 23, 1918, pp. 387-389 and 404-407, 3 figs. Concerning regenerative devices, use of powdered fuel, continuousness of operation, use of compressed air. Plans of ideal modern smithy.

FOUNDRIES

Brass Melting

Melting Brass in a Rocking Electric Furnace, H. W. Gillett and A. E. Rhoads. Department of Interior, Bur. of Mines, Bul. 171, Min. Technology 23, 131 pp., 6 figs. Sets forth in detail possibilities and limitations of electric brass melting and compares various types of furnaces. Also Water & Gas Rev., vol. 29, no. 6, Dec. 1918, pp. 9-11.

Chaplets

Obtaining Best Results from Use of Chaplets, Ernest Schwartz. Foundry, vol. 47, no. 317, Jan. 1919, pp. 14-15, 14 figs. Removal or prevention of rust and precautions against excessive moisture essential to prevent blowholes; choosing types and sizes for various purposes.

Core Room

Core-Room of T. H. Symington Co., Rochester, Donald S. Barrows. Can. Foundryman, vol. 9, no. 12, Dec. 1918, pp. 296-299, 9 figs. Arrangement intended to provide good ventilation and lighting.

Efficiency in the Core Room, J. B. Conway. Am. Mach., vol. 50, no. 1, Jan. 2, 1919, pp. 11-14, 6 figs. Conclusions reached as result of investigation into conditions of efficiency and production in southern factory and remedies applied.

Cupola

Operation of a Cupola, William Lanten. Metal Trades, vol. 9, no. 11, Nov. 1918, pp. 461-463, 2 figs. Account of experiments with column charging.

Foundries

Continuous Two-Story Foundry Proves Economical, J. F. Ervin. Foundry, vol. 47, no. 317, Jan. 1919, pp. 40-42, 2 figs. States that extensive handling operations in modern foundry are most readily performed in building of multi-story design. From paper before Am. Foundrymen's Assn.

Unique Features of an Illinois Foundry, Charles Lundberg. Iron Age, vol. 102, no. 26, Dec. 26, 1918, pp. 1563-1569, 13 figs. Electric steel, gray iron and semi-steel departments; continuous operations with large production in small space; use of molding machines. Description of plant of Avery Co., Peoria, Ill.

Molding

How Gear Cases for Tractors Are Molded. Foundry, vol. 47, no. 317, Jan. 1919, pp. 2-5, 8 figs. Molding machines of large capacity and special core-room equipment are employed; special rigging for economies.

Patterns and Their Relation to Molding Problems, Joseph A. Shelly. Machy., vol. 25, no. 4, Dec. 1918, pp. 310-314, 12 figs. First of series of articles dealing with construction and application of patterns, including use of woodworking tools, art of joinery, and various methods of building patterns and core boxes.

Salvage Work

Reclaiming Wealth in the Foundry Yard, F. B. Hicks. Can. Foundryman, vol. 9, no. 12, Dec. 1918, pp. 302-303. Salvage work conducted by a superintendent of Sawyer-Massey works.

War Demands

Shell Need Found Foundries Ready. Iron Trade Rev., vol. 63, no. 22, Nov. 28, 1918, pp. 1229-1236, 15 figs. Methods developed in American foundries to meet increased demand of production.

See also *ELECTRICAL ENGINEERING, Furnaces (Industrial Furnaces, Steel Furnaces).*

FUELS AND FIRING

Blast-Furnace Gas

The Use of Blast-Furnace Gas for Heating Boilers and Metallurgical Apparatus (L'emploi du gaz pour le chauffage des chaudières et des appareils métallurgiques), H. Thiry. Génie Civil, vol. 73, no. 21, Nov. 23, 1918, pp. 401-404, 8 figs. Precautions necessary to insure successful operation of Cowper system. Abstract of discussion before South Wales Inst. Engrs. and Cleveland Inst. Engrs.

Briquetting

The Economy of Briquetting Small Coal, J. A. Yeadon. Trans. Instn. Min. Engrs., vol. 56, part 1, Nov. 1918, pp. 31-34 and (discussion) pp. 34-36. Considerations on conservation of coal and utilization of waste materials; advantages of briquetting; method of manufacture; rectangular and ovoid forms of briquets.

Chimney Design

Saving the Waste in the Chimney, Robert Sibley and Chas. H. Delany. Jl. Elec., vol. 41, nos. 10 and 11, Nov. 15 and Dec. 1, 1918, pp. 463-464 and 511, 4 figs. Nov. 15: Fundamental laws of chimney design as applied to economic operation of oil-fired power plant. Dec. 1: Draft formula for modern power plant.

Combustion Characteristics of Coal

Combustion Characteristics of Coals. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 495-497, 5 figs. Factors entering into success of equipment selected for burning different kinds of coal; performance of various types of stokers; data on grades of coal.

Generation of Heat from Bituminous Coal and Its Absorption by the Boiler, Henry Misostow. Power, vol. 48, no. 25, Dec. 17, 1918, pp. 898-899, 3 figs. From paper before National Assoc. of Stationary Engrs., Cincinnati, Sept. 1918.

Considerations and Practical Conclusions in Regard to the Combustion and Gasification of Carbon (Considerations diverses et conséquences pratiques au sujet de la combustion et de la gazéification du carbone), J. Seigle. Bulletin et Comptes rendus mensuels de la Société de l'Industrie Minérale, series 5, vol. 14, 3d issue 1918, pp. 79-112, 7 figs. Chemical and thermodynamic equations. Air is considered as $O_2 + 4N_2$. Examination of changes and combinations in coke gas producers.

Combustion Characteristics of Coal, Joseph G. Worker. Ry. Rev., vol. 63, no. 23, Dec. 7, 1918, pp. 824-827. Behavior of different grades of stationary boiler plant fuel with reference to type of mechanical stoking apparatus best suited for it. Fuels treated range from small sizes of anthracite through several grades and qualities of bituminous and lignites.

Combustion Characteristics of Coals and Selection of Suitable Stoker Equipment, Joseph G. Worker. Railroad Herald, vol. 23, no. 1, Dec. 1918, pp. 9-14, 7 figs. Results of tests on overfeed type of stoker with smaller sizes of nos. 1, 2 and 3 buckwheat coal and tables giving performance of underfeed stoker as applied to various sizes of boilers and burning different grades of coal.

Fuel Conservation

The Fuel Situation in New England, B. B. Pollock. Official Proc. N. Y. R. R. Club, vol. 29, no. 1, Dec. 1918, pp. 5455-5456. Measures taken to meet coal shortage by Federal Administrator, Boston & Maine R. R.

Some Important Points in Fuel Conservation, Robert Collett. Ry. Age, vol. 65, no. 25, Dec. 20, 1918, pp. 1121-1123. Why we must still save fuel; plan of organization; lessons learned from personal experience. From paper before New England Railroad Club.

Hand-Fired Plants

Fuel Economy in Hand-Fired Power Plants —V, Power Plant Eng., vol. 22, no. 24, Dec. 15, 1918, pp. 987-989. Feed water heating and purification. Abstract of circular 7, Univ. Ill. Eng. Experiment Station.

Indiana Coals

Burning Indiana Coal on the Chain Grate, T. A. Marsh. Power, vol. 49, no. 1, Jan. 7, 1919, pp. 17-19, 7 figs. Characteristics of Indiana screenings from four seams supplying most of steaming coal; need of large grate area, large furnace volume and strong draft to give capacity, and long, high-pitched arches.

Iowa Coals

Burning the Low-Grade Coal of Iowa, T. A. Marsh. Power, vol. 48, no. 27, Dec. 31, 1918, pp. 940-941, 4 figs. Burning Iowa coal on chain grate. Being low in heat value, high in ash and of clinkering, non-coking variety, this coal requires, for successful burning, practically continuous ash disposal and non-agitation of fire. Also Elec. World, vol. 72, no. 25, Dec. 21, 1918, pp. 1166-1168, 4 figs. General considerations to observe in selecting stokers and in designing furnaces; specific changes which can be made in order to adapt existing stokers to low-grade fuels.

Lignites

The Firing of Pulverized Lignite, M. C. Hatch. Jl. Elec., vol. 41, no. 12, Dec. 15, 1918, pp. 539-541. Advantages in pulverizing; methods of handling; furnace design for pulverized fuel; calculation of total cost.

Notes on Lignite, Its Characteristics and Utilization, S. M. Darling. Power House, vol. 11, no. 11, Nov. 1918, pp. 328-331. Abstract of U. S. Bureau of Mines paper.

Powdered Coal

Pulverized Coal and Its Preparation, J. M. Wadsworth. Jl. Elec., vol. 41, no. 11, Dec. 1, 1918, pp. 511-512, 2 figs. Arrangement of machinery in small coal pulverizing plant. Compiled for Western needs by technical staff of Fuel Administration. First of series.

Stokers

Power Plant Management VI Mechanical Stokers, Robert June. Refrig. World, vol. 53, no. 12, Dec. 1918, pp. 23-25, 3 figs. Efficiency of stokers; smoke alleviation; characteristics of individual chain-grate stokers.

Storage

Effect of Storage on Coal (II), Coal Trade Jl., year 50, no. 51, Dec. 1918, pp. 1481-1482. Analytical data accumulated during weathering tests made by Eng. Experiment Station of Univ. of Ill. Tests covered period of six years. Coals used were from Illinois field. (Continuation of serial.)

Wood

Waste Wood as a Fuel Possibility, O. F. Stafford. Jl. Elec., vol. 41, no. 12, Dec. 15, 1918, pp. 541-543. Suggests conversion of wood waste into ethyl alcohol, direct fuel and powdered charcoal which might be used directly in specially designed Diesel engine.

FURNACES

Annealing Furnaces

Continuous Type Annealing Furance, Philip d'H. Dressler. Iron Trade Rev., vol. 63, no. 25, Dec. 19, 1918, pp. 1416-1417, 5 figs. Deals specially with a form of continuous car-type annealing furnace. Discussion of H. E. Diller's paper before Am. Foundrymen's Assn.

Heat Treating

Equipment Data on Heat Treat Furnaces. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 437-439, 6 figs. Discusses refractory material, fuel-oil burners and other furnace equipment.

Insulation

Value of Heat Insulation in Furnaces, A. W. Knight. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 451-453. Discusses particularly use of insulation as applied to annealing ovens.

Pressures

Graphical Examination of Pressures of Hot Gases and Vapors in Furnaces and Chimneys (Etude de quelques cas généraux de pression des gaz chauds et fumées dans les fours et cheminées par représentation graphique), J. Seigle. Bulletin et comptes rendus mensuels de la Société de l'Industrie Minérale, series 5, vol. 14, 3d issue 1918, pp. 133-151, 17 figs. Variation of pressure at different points of enclosure containing hot gases when (1) enclosure is open at top, (2) open at bottom, and when (3) it connects with another enclosure by conduit at top.

HANDLING OF MATERIALS

Dumper

Dumper at Sewalls Point Handles Two Cars at Once. Eng. News-Rec., vol. 81, no. 24, Dec. 12, 1918, pp. 1086-1088, 5 figs. New facilities of Virginian Ry. at coal pier near Norfolk also include cars of 120 tons capacity, and long incline.

Double Car Dumper for Handling Coal, A. F. Case. Iron Age, vol. 102, no. 24, Dec. 12, 1918, pp. 1435-1438, 7 figs. Description of new Sewalls Point plant of Virginian Ry. Co.

HEAT TREATING

Malleable Iron

Tests in Annealing Malleable Iron, H. E. Diller. Iron Trade Rev., vol. 63, no. 25, Dec. 19, 1918, pp. 1414-1416, 4 figs. Experiments conducted to determine time necessary for annealing; study of results and indication of possibility of annealing in 48 hr.; photomicrographs, description of continuous car-type heating furnace. Paper at annual meeting of Am. Foundrymen's Assn.

Steel

Art of Heat Treating, D. N. A. Blacet. Ry. Jl., vol. 25, no. 1, Jan. 1919, pp. 18-20. Economical aspect of adding metallurgist to personnel of plants manufacturing steel parts; general considerations regarding selection of specifications. From Jl. Am. Steel Treaters' Soc.

Surface Combustion

Application of the Surface Combustion Process to Heat Treating and Similar Work, John D. Bartlett, Jr. Proc. Steel Treating Soc., vol. 1, no. 11, pp. 18-32, 12 figs. Generation and application of heat; proportioning of gas and air mixture; description of several installations for heat treating; automatic heat-treating furnaces for large-size shells.

HEATING AND VENTILATION

Circulation Heating

Heating Shop Floors by Circulation. Metal Worker, vol. 90, no. 24, Dec. 13, 1918, pp. 662-663, 6 figs. Scheme to draw cold air from the floor.

Factory Heating

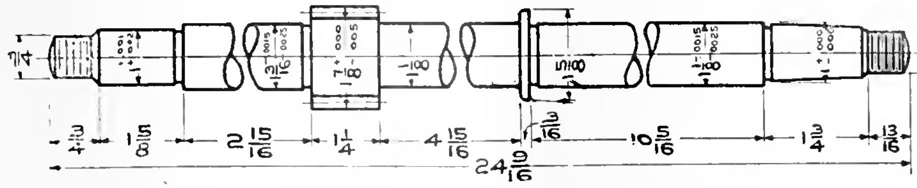
Fuel Wastes in Factory Heating, Charles L. Hubbard. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 23-25. Sources of losses; suggestions for economies; means for temperature control suited to different systems of heating.

Hospitals

Heating and Power Plant Economies for Hospitals, J. D. Kimball. Modern Hospital, vol. 11, no. 6, Dec. 1918, pp. 437-439. Fundamentals and recommendations of National Economy Program. Paper for convention of Am. Hospital Assn.

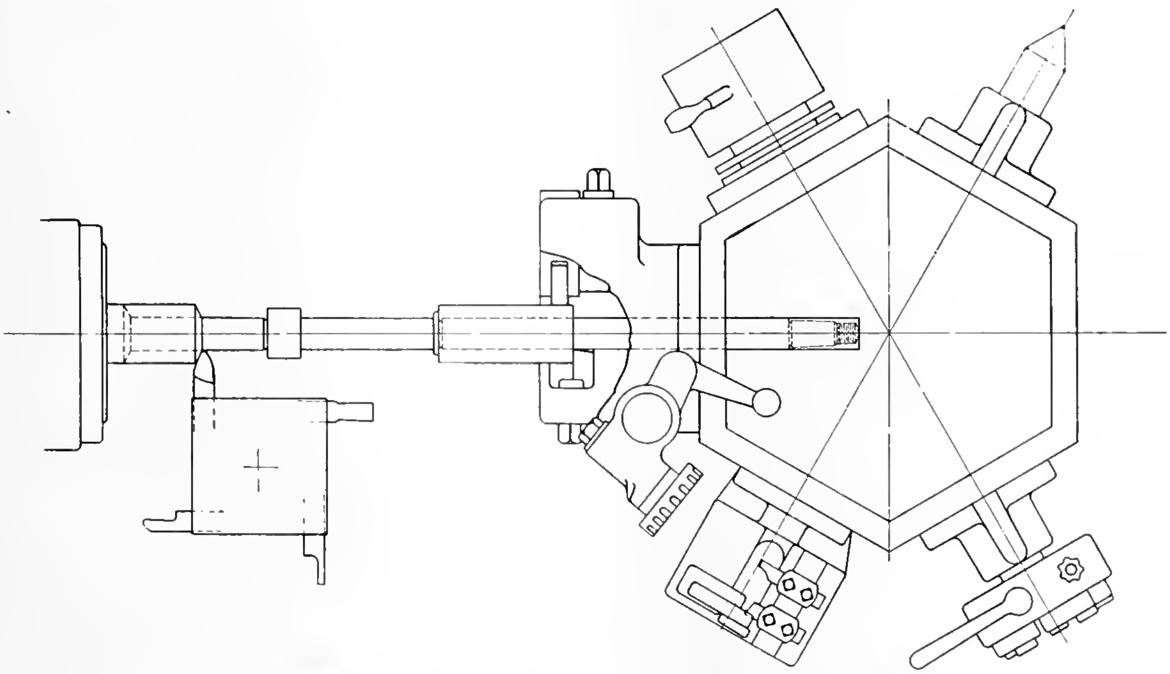
Moisture Removal

The Removal of Moisture from Special Rooms and Buildings, Charles L. Hubbard. Domestic Eng., vol. 85, no. 8, Nov. 23, 1918, pp. 283-285 and 313-315, 6 figs. Notes on in-



Follow This Thru

YOU will spend your time profitably by analyzing each operation in producing this shaft on the No. 2-A Universal Hollow Hexagon Turret Lathe.



1st Operation:—Turn the 1⅛ in. diameter with the turning tool. At the same time, with a cutter in the square turret, form the 1⅝ in. shoulder and turn the 1⅛ in. diameter behind the shoulder. With another square turret cutter, turn the 1⅞ in. and 1 3-16 in. diameter. The two turrets finishing their work simultaneously.

2nd Operation:—Turn the ¾ in. diameter.
3rd Operation:—Center Shaft.
4th Operation:—Turn the 1 in. tapered diameter with taper attachment and nick with square turrent cutter.
5th Operation:—Thread ¾ in. diameter.
6th Operation:—Cut off.

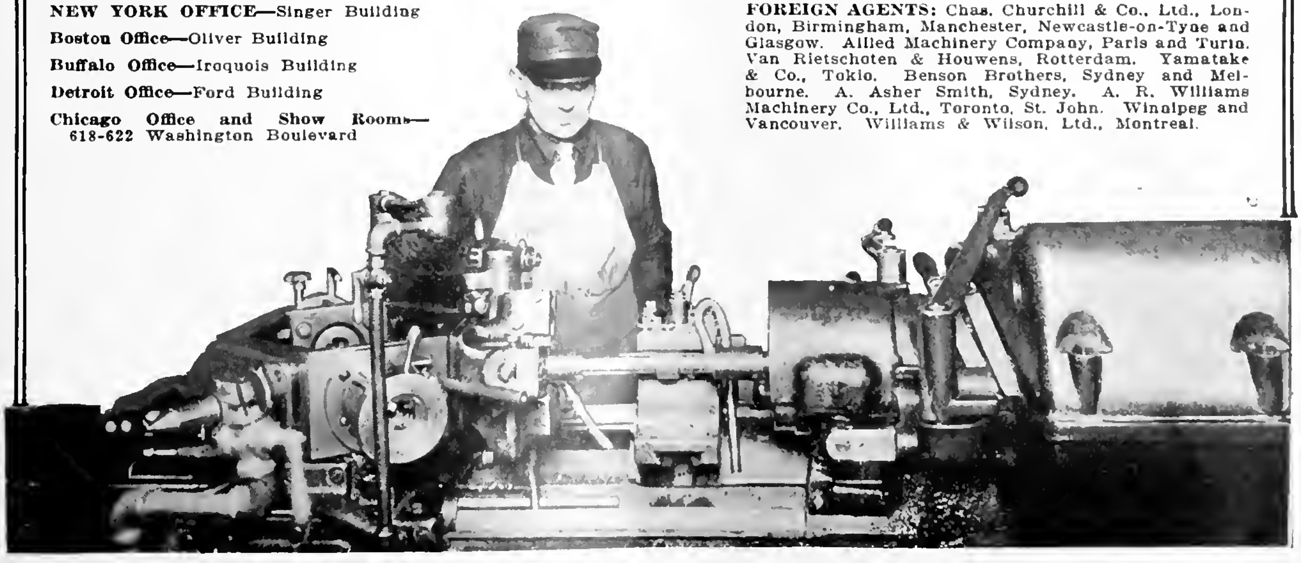
Warner & Swasey turret lathes will mean sure profits to you. Send blueprints for an analysis like the shaft job here.

THE WARNER & SWASEY COMPANY

CLEVELAND, OHIO, U. S. A.

NEW YORK OFFICE—Singer Building
Boston Office—Oliver Building
Buffalo Office—Iroquois Building
Detroit Office—Ford Building
Chicago Office and Show Rooms—618-622 Washington Boulevard

FOREIGN AGENTS: Chas. Churchill & Co., Ltd., London, Birmingham, Manchester, Newcastle-on-Tyne and Glasgow. Allied Machinery Company, Paris and Turin. Van Rietschoten & Houwens, Rotterdam. Yamatake & Co., Tokio. Benson Brothers, Sydney and Melbourne. A. Asher Smith, Sydney. A. R. Williams Machinery Co., Ltd., Toronto, St. John. Winnipeg and Vancouver. Williams & Wilson, Ltd., Montreal.



stallation of ventilating systems in laundries, dye houses, paper mills, foundries, flax mills, etc.

Office-Building Ventilation

Air Supply for a Large General Office Building, Samuel R. Lewis. Heat & Vent. Mag., vol. 15, no. 12, Dec. 1918, pp. 21-36, 16 figs. Past and present practice illustrated in remarkable installation for Swift & Co., Chicago.

Radiators

Figuring Direct Radiator Heating Service, W. B. Gray. Metal Worker, vol. 90, no. 24, Dec. 13, 1918, pp. 653-655 and 658, 2 figs. Describes method said to insure correctness and to be of practical application by heating contractors.

Rector System of Gas Heating

New Heating System, Geo. S. Barrows. Gas Indus., vol. 18, no. 12, Dec. 1918, pp. 363-369, 7 figs. Extensive description of Rector system of gas heating.

Steam Heating

Care of Heating and Ventilating Equipment, Harold L. Alt. Power, vol. 48, no. 26, Dec. 24, 1918, pp. 910-912, 3 figs. Describes gravity one-pipe steam system. (Sixth article.)

HOISTING AND CONVEYING

Cableways

Aerial Cableways Successful in Northwest Shipyards. Eng. News-Rec., vol. 82, no. 1, Jan. 2, 1919, pp. 37-40, 5 figs. Similar to loggers cableways; ability to get men expert in handling them is one secret of success; well-planned installations are fast and flexible.

Cranes

Stothert-Pitt 35-Ton Locomotive Crane (Grue-locomotive de 35 tonnes système Stothert et Pitt.) Génie Civil, vol. 73, no. 11, Sept. 14, 1918, pp. 201-203, 5 figs. General arrangement and plans showing dimensions.

HYDRAULIC MACHINERY

Conduits, Loss of Pressure Head

On the High Velocities of Water in Conduits (Sur les grandes vitesses de l'eau dans les conduites), C. Mamichel. Revue Générale de l'Electricité, vol. 4, no. 21, Nov. 23, 1918, pp. 788-790, 1 fig. Experimental results said to have demonstrated loss of pressure head for velocities up to 260 ft. per sec. to be the same as for velocities of 30 ft. per sec.

Penstock Pipe

Saving the Waste in Penstock Pipe Design II), B. F. Jakobsen. Jl. Elec., vol. 41, no. 11, Dec. 1, 1918, pp. 504-505, 2 figs. Presentation and discussion of various formulæ to determine manner in which available money should be distributed among different items in order to get maximum economy. (Continued from Nov. 1 issue.)

Water Hammer

Maxima Excess Pressures Produced by Water Hammer (Sovrapressioni massime nei fenomeni del colpo d'ariete), Maurice Gariel. Abstract of article published in Revue Générale de l'Electricité, Sept. 21. (See Eng. Index, Jan., Mech. Eng., Hydraulic Machy., Water Hammer.)

Notes on the Size and Location in Forced Conduits of Water Hammer Relief Devices. (Remarques au sujet des conditions à remplir par certains dispositifs destinés a attenuer les coups de bélier dans les conduites forcées). Comte de Sparre. Revue Générale de l'Electricité, vol. 4, nos. 19 and 20, Nov. 9 and 16, 1918, pp. 685-690 and 731-740, 1 fig. Nov. 9: Mathematical analysis of phenomena taking place, by reason of elasticity of water and conduit, in surge tank which opens a compensating orifice when water hammer reaches a certain value, the orifice having such dimensions that water hammer will never exceed a permissible maximum. Nov. 16: Application of principles established in preceding installment to calculation of permissible minimum dimensions of surge tanks which will insure a constant value of water hammer during compression.

INTERNAL-COMBUSTION ENGINES

Buckeye Barrett Engine

Buckeye Barrett Crude Oil Engine. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 72-73, 2 figs. Low-compression type burning heavier grades of fuel and designed for service where an engine must run for weeks under full load without a stop.

Design

The Working Process of Internal Combustion Engines, P. H. Sherbondy. Aerial Age, vol. 8, no. 11, Nov. 25, 1918, pp. 564-568, 7 figs. Historical review of inventions which have tended to improve engine efficiency.

Internal Combustion Engine Development, R. E. Neale. Eng. Rev., vol. 32, no. 5, Nov. 15, 1918, pp. 130-132. Indicates lines open to further development particularly in direction of lightening low-speed engines by adoption of higher piston speeds. (To be continued.)

Diesel-Engine Fuel Pumps

The Design and Construction of Diesel Engine Fuel Pumps, G. L. Kirk. Engineering, vol. 106, no. 2759, Nov. 15, 1918, pp. 549-551, 10 figs. Four systems of oil distribution; system of regulation; determination of clearances; constructional details; control lever.

Ignition

Operation of Internal-Combustion-Engine Magnetos (Sul funzionamento dei magneti di accensione dei motori a scoppio), Emilio Biffi. L'Elettrotecnica, vol. 5, no. 29, Oct. 15, 1918, pp. 407-411, 6 figs. Various aspects of spark; study of its oscillatory character; conclusions in regard to magneto operation. (Concluded.)

Ignition Timing and Valve Setting, Vermont Wells. Am. Blacksmith, vol. 17, no. 12, Sept. 1918, pp. 291-293, 4 figs. Rules for timing ignition in different makes of cars.

British Magneto Manufacture. Gas & Oil Power, vol. 14, no. 158, Nov. 7, 1918, pp. 20-22, 3 figs. General dimensions and brief outline of magneto manufactured by British Lighting and Ignition Co.

Dixie Standard Aircraft Magnetos. Automotive Indus., vol. 39, no. 23, Dec. 5, 1918, pp. 954-957, 6 figs. Type which may be adapted to various engines; methods used in manufacture of magneto magnets.

Semi-Diesel Engines

Semi-Diesel Oil Engines, F. D. Weber. Jl. Elec., vol. 41, no. 12, Dec. 15, 1918, pp. 549-550, 4 figs. Types being used to equip auxiliary wooden schooners of 500 to 3000 tons capacity and straight motor schooners up to 1000 tons capacity.

The Semi-Diesel Oil Engine, James Richardson. Gas & Oil Power, vol. 14, no. 158, Nov. 7, 1918, pp. 23-25, 9 figs. Development and operation. From paper before Diesel Engine Users' Assn. Also Macy. Market, no. 944, Dec. 6, 1918, pp. 17-18, 9 figs. Definition; compression pressure; flexibility; range of working.

Valves, Poppet, Air Flow Through

Air Flow Through Poppet Valves. Automotive Indus., vol. 39, no. 25, Dec. 19, 1918, pp. 1047-1051, 5 figs. Experimental investigation from which writer concludes that coefficient of efflux is practically constant for all pressure drops and nearly the same for valves of different sizes, at equal lifts expressed in per cent. of their respective diameters; considerations on number of inlet valves to use.

Air Flow Through Poppet Valves. Automotive Eng., vol. 3, no. 10, Dec. 1918, pp. 461-463, 1 fig. Data on valve sizes; investigation of merits of multiple valves. (To be continued.)

Winton Marine Engine

The Latest Winton Marine Oil Engine. Automotive Eng., vol. 3, no. 10, Dec. 1918, pp. 447-450, 5 figs. Review of mechanical details of 500 and 250-hp. units of Diesel-type reversible motor.

See also ELECTRICAL ENGINEERING, *Electrophysics (Spark Plug Insulators).*

LUBRICATION

Bearing Design

Oiling System and Bearing Designs, A. E. Windram. Tran. Inst. Marine Engrs., vol. 30, no. 238, Oct. 1918, pp. 209-216, 13 figs. Method of making main bearing, crankpin and crosshead brasses oiltight by means of drilling crank webs into oil rings or grooves turned round center of journal, and corresponding oil ring or groove in center of brasses connected with pipes from brasses to brasses, which are made oiltight by sealing rings on ends of brasses.

Oils

Properties of Oils and Their Relation to Lubrication (Propiedades de los aceites; su relacion con la lubricación). Boletin de la Sociedad de Fomento Fabril, year 35, no. 8, Aug. 1918, pp. 537-542. Significance of tests for acidity, carbon-residue, oxidation, volatility, surface tension, emulsion, heat and density.

See also MARINE ENGINEERING, *Ships (Lubrication).*

MACHINE ELEMENTS AND DESIGN

Crankshafts

Hair-Line Defects in Crankshafts, P. J. Piccirilli. Automotive Industries, vol. 39, nos. 25 and 26, Dec. 19 and 26, 1918, pp. 1041-1044, 1104-1105 and 1122, 15 figs. Metallographic study and physical tests of chrome-nickel steel crankshafts to determine nature and effect of so-called hair-line defects on their physical strength.

Springs

A new theory of Plate Springs, David Landau and Percy H. Parr. Jl. Franklin Inst., vol. 186, no. 6, Dec. 1918, pp. 699-721, 8 figs. Mathematical generalization of propositions advanced in first paper, vol. 185, Apr. 1918, p. 481. Special attention given to effect of tapering ends and constructing springs so that leaves continue in contact everywhere on application of load. (To be concluded.)

The Springs of the Car (IV), F. M. Paul. Am. Blacksmith, vol. 17, no. 12, Sept. 1918, pp. 298-299, 8 figs. Considers effect of thickness in regard to deflection and load.

MACHINE SHOP

Chisel

The Cold Chisel, J. A. Lucas. Power, vol. 48, no. 24, Dec. 10, 1918, pp. 838-841, 27 figs. Description of various types of cold chisels and their uses.

Cylinder Manufacture

Cylinder Boring and Reaming, Franklin D. Jones. Machy., vol. 25, no. 5, January 1919, pp. 383-394, 20 figs. First of series of articles dealing with boring, reaming and grinding of cylinders, and tools, fixtures and machines used.

Manufacture of Cylinders for the Hall-Scott Aeroplane Engine, Richard Vosbrink. Metal Trades, vol. 9, no. 12, Dec. 1918, pp. 475-479, 11 figs. Operations followed at California plant to produce accurate results.

Design

Novel Plant of American Tool Company, C. L. Smith. Iron Age, vol. 103, no. 1, Jan. 2, 1918, pp. 29-33, 10 figs. Latest ideas in heating and ventilating, lighting features, transportation facilities, sanitation, handling turnings; unusual drive for planers; machine foundations.

Designing a Shop for Present Day Needs, C. E. Edmund. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 431-433. Considerations on location, construction and operation of forge plant.

Gages

Notes on the Computing of Gauge Tolerances, M. H. Potter. Can. Machy., vol. 20, no. 24, Dec. 12, 1918, pp. 670-672, 6 figs. Classifies and studies the more frequent troubles experienced with gages and gives rules and formulæ for computing allowable tolerances for various gages. A square hole gage and a depth gage are referred to but the rules proposed apply in general to all gages.

Apparatus for Checking Screw Threads. Automotive Indus., vol. 38, no. 24, Dec. 12, 1918, pp. 1008-1010, 4 figs. Methods of operating machines used for inspection of plug and ring thread gages and similar threaded parts requiring great accuracy.

Flush-pin, Sliding Bar and Hole Gages, Erik Oberg. Machy., vol. 25, no. 5, Jan. 1919, pp. 404-412, 34 figs. Principles involved and procedure followed by Pratt & Whitney Co. in developing gaging systems for interchangeable manufacture. Fourth article.

Contour or Profile Gages, Erik Oberg. Machy., vol. 25, no. 4, Dec. 1918, pp. 301-308, 31 figs. Principles involved and procedure followed in developing gaging systems for interchangeable manufacture. Based upon experience of Pratt & Whitney Co. in furnishing gaging equipment for small arms and heavy ordnance work. Third article.

Gear Cutting

The Manufacture of Spiral Bevels. Automobile Engr., vol. 8, no. 121, Dec. 1918, pp. 336-339, 6 figs. Description of Gleason machine for that purpose.

Problem of the Theoretically Correct Involute Hob, Nikola Trbojevich. Machy., vol. 25, no. 5, Jan. 1919, pp. 429-433, 3 figs. Mathematical theory developed.

Grinding

Grinding of Hardened Work, C. H. Norton. Proc. Steel Treating Research Soc., vol. 1, no. 11, pp. 15-17. Norton Grinding Co.'s experience; suggestions in regard to grinding.

Grinding Operations on "Caterpillar" Tractor Parts, Frank A. Stanley. Am. Mach., vol. 50, no. 1, Jan. 2, 1919, pp. 1-4, 7 figs. Grinding operations include finishing of great variety of gears, bushings, shafts, piston pins, case covers, etc.; details of wheels, limits of accuracy, etc.

Grinding Round Work Without Centers. Am. Mach., vol. 50, no. 1, Jan. 2, 1919, pp. 4-5, 4 figs. Describes new grinding machine built by Detroit Tool Co.

Pistons and Rings

The Manufacture of Pistons and Rings, A. Thomas. Automobile Engr., vol. 8, no. 121, Dec. 1918, p. 358, 3 figs. Notes on operation of Potter-Johnston automatic machine.

Repair Work

Automotive Repair Work in the Machine Shop, Donald A. Hampson. Can. Machy., vol. 20, no. 24, Dec. 12, 1918, pp. 665-668, 7 figs. Practical observations on methods of increasing pedal leverage, making a working clutch, inserting cotters in unseen holes, fitting rings in cylinder, increasing size of cast-iron parts, reaming undersize in cast iron and other similar operations.

The Repair Shop, Automobile Engr., vol. 8, nos. 120 and 121, Nov. 1918 and Dec. 1918, pp. 312-315 and 341-345, 25 figs. Nov. 1918: Notes on heavy vehicle design from viewpoint of repair and maintenance. Radiator; engine; clutch; engine suspension; gear box; universal joints and brakes. Dec. 1918: Deals with rear axle; road wheels and bearings; chassis lubrication, spring and pins; frame; steering and front axle; controls.

MACHINERY, METAL-WORKING

Boring Mill

Blomquist-Eck Horizontal Boring Mill. Machy., vol. 25, no. 5, Jan. 1919, pp. 465-466, 2 figs. General description with illustrations.

Lathes

Large Lathes for Machining Turbine Spindles, A. M. M. Machy., vol. 25, no. 5, Jan. 1919, pp. 439-442, 4 figs. Illustrated description of some large lathes.

Planer

Newton Upright Generating Planer. Machy., vol. 25, no. 5, Jan. 1919, pp. 473-474, 4 figs. Description of machine built by Newton Machine Tool Works, Inc., Philadelphia, Pa.

Reamers

Types of Reamers and Their Use, E. C. Peck. Machy., vol. 25, no. 4, Dec. 1918, pp. 335-337, 6 figs. Description of various types of reamers.

Relieving Machine

Universal Relieving Machine for Hobs and Cutters. Machy., vol. 25, no. 5, Jan. 1919, pp. 467-468, 2 figs. Description of machine built by T. C. M. Mfg. Co., Harrison, N. J.

Steel, High-Speed

The Evolution of a High-Speed Steel Tool, T. L. Thorne. Proc. Steel Treating Research Soc., vol. 1, no. 11, pp. 33-43. Analyses of several high-speed steel specimens; influence of silicon, manganese, sulphur, phosphorus, chromium, vanadium and tungsten on characteristic properties of steel; practice followed in its manufacture; forms of furnaces used; heat-treating and tools.

A New Air-Hardening High-Speed Steel. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 435-436, 2 figs. Experiences of users of a steel made without tungsten by Cuyahoga Crucible Foundry Co.

Stellite

Stellite and High-Speed Steel Compared. Iron Age, vol. 102, no. 26, Dec. 26, 1918, pp. 1584-1585, 2 figs. Hardness at different temperatures; stellite softer in raw state; relative cutting tests on three materials.

See also RAILROAD ENGINEERING, Shops (Tools, Brass-Working); MUNITIONS AND MILITARY ENGINEERING, Tools for Shell Manufacture.

MATERIALS OF CONSTRUCTION AND TESTING OF MATERIALS

Notched Bars

Some Experiments on Notched Bars, H. T. Philpot. Jl. Soc. Automotive Engrs., vol. 3, no. 6, Dec. 1918, pp. 347-357, 3 figs. Tests to obtain dimensions and shapes for round notched bar for use in acceptance tests on heat treated steels in place of standard square type A test piece. Paper before Instn. Automobile Engrs. of Great Britain.

Hardness

The Ludwik Hardness Test, W. Cawthorne Unwin. Jl. Instn. Mech. Engrs., no. 6, Nov. 1918, pp. 485-492. Traces relationship between indentation hardness tests of ductile metals.

The Value of the Indentation Method in the Determination of Hardness, R. G. C. Batson. Jl. Instn. Mech. Engrs., no. 6, Nov. 1918, pp. 463-483, 6 figs. Deals with determination of hardness by means of indentation produced by a static load and by impact of a ball or cone.

Malleable Iron

Malleable Iron in Engineering Construction, H. A. Schwartz. Foundry, vol. 47, no. 317, Jan. 1919, pp. 19-24, 16 figs. Engineering properties and characteristics of malleable iron which recommend it for wide range of uses. From paper before Am. Foundrymen's Assn.

Optical Stress Determination

Stress Optical Experiments, A. R. Low. Flight, vol. 10, nos. 48-49, Nov. 28 and Dec. 5, 1918, pp. 1355-1356 and 1379-1381, 12 figs. Determination of stress by optical methods. Nov. 28: Elementary theory; changes in uniform field as stress increases; null method of measurement; appearances in non-uniform field; neutral, isochromatic and isoclinic lines. Dec. 5: Simplifications in case of bar under flexure; error of obliquity; observation of errors of parallax; general accuracy of optical observations of stress. Paper before Royal Aeronautical Soc. (To be continued.)

Rubber

Ageing of Vulcanized Plantation Rubber, Henry P. Stevens. Jl. Soc. Chem. Indus., vol. 37, no. 21, Nov. 15, 1918, pp. 305T-306T, 4 figs. Tests on ordinary pale rolled sheet and unrolled sheet.

Testing Machines

Testing Machines in Industrial Laboratories, H. S. Primrose and J. S. Glen Primrose. Can. Machy., vol. 20, nos. 23 and 25, Dec. 5 and 19, 1918, pp. 644-647 and 696-699, 17 figs. Necessity of establishing specifications properly controlled by analysis and test in purchasing engineering materials and features of various testing machines. From Engineering.

Testing of Materials

The Experimental Study of the Mechanical Properties of Materials, W. Cawthorne Unwin. Jl. Instn. Mech. Engrs., no. 6, Nov. 1918, pp. 405-439, 13 figs. Early researches; chain-cable testing machines; calibration of testing machines; large testing machines; Emery testing machine at Bureau of Standards; tests of reception-tension tests, Wöhler test, hardness tests, notched-bar tests.

Wood

Some Tests of Douglas Fir after Long Use, Arthur C. Alvarez. Univ. of Cal. Publications in Eng., vol. 2, no. 2, Nov. 18, 1918, pp. 57-118, 17 figs. Results of 1200 tests on strength, elastic properties and moisture content; includes 27 tables of measured and computed mechanical coefficients.

MEASUREMENTS AND MEASURING APPARATUS

Calibration

On the Choice of a Uniform Temperature for the Calibration of Measuring Instruments (Sur le choix d'un degré uniforme de température pour l'étalonnage des instruments de mesure), Ch. Cochet. Revue Générale de l'Electricité, vol. 4, no. 20, Nov. 16, 1918, pp. 740-742. Report of Commission de Normalisation des Ingénieurs des Arts et Métiers de Boulogne-sur-Seine, recommending adoption of 0 deg. cent. as standard.

Calorimeters

Calorimetric Methods and Devices, Walter P. White. Jl. Am. Chem. Soc., vol. 40, no. 12, Dec. 1918, pp. 1887-1889, 3 figs. Application of rules for calorimetric precision derived by writer to jacket covers and stirrers; vacuum-jacketed vessels; adiabatic method; aneroid or dry calorimeters; double or differential calorimeters; measured-shield calorimeters.

Coke Testing

Coke Factors Affecting Furnace Operation, G. D. Cochrane. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 502-504 and 512, 1 fig. Coke-testing machine employed in experiment for determining coke hardness. Mechanical condition of coke an important factor in furnace operation.

Picnometer

A Picnometer Operated as a Volumeter, H. G. Schurecht. Jl. Am. Ceramic Soc., vol. 1, no. 8, Aug. 1918, pp. 556-558, 1 fig. Same as ordinary picnometer but of sufficiently large size and opening to permit introduction of a briquet into the bottle. Volume of briquet determined from standard formula in terms of weight and specific gravity of liquid.

Salinometers

An Instrument for Recording Sea-Water Salinity, A. L. Thuras. Jl. Wash. Acad. Sci., vol. 8, no. 21, Dec. 19, 1918, pp. 676-687, 3 figs. Surface salinity of ocean determined by measuring ratio of resistances of sea water in two similar electrolytic cells. Accuracy, limited by that with which salinity of standard sea water carried in sealed cell is known. Table given showing conductivity of sea water throughout range of concentration found in open ocean.

Scales

Oscillations in Scales, Eugene Motchman. Scale Jl., vol. 5, no. 3, Dec. 10, 1918, pp. 7-9, 4 figs. Use of modern 150-ton beam applied to railroad track scales without loose weight. (Continuation of serial.)

MECHANICAL PROCESSES

Boilers

Boiler Making in an English Shop, A. L. Haas. Boiler Maker, vol. 18, no. 12, Dec. 1918, pp. 333-337, 11 figs. Hopwood, Cornish, Lancashire and Britannia types; shop conditions; position drilling; combustion chamber crown; seven-hour test.

Manufacturing Marine Steam Boilers, E. A. Suverkrop. Am. Mach., vol. 49, no. 26, Dec. 26, 1918, pp. 1155-1163, 21 figs. Description of building operations of single-ended, three-furnace Scotch marine boilers at shop of Sun Shipbuilding Co., Chester, Pa., where production has reached as high as nine per month.

Cans

A Modern Can-Making Plant in a Baking Powder Factory, J. V. Hunter. Am. Mach., vol. 49, no. 26, Dec. 26, 1918, pp. 1173-1176, 11 figs. Description of process of making tin cans.

Chains

The Manufacture of Diamond Transmission Chain, J. V. Hunter. Am. Mach., vol. 49, no. 23, Dec. 12, 1918, pp. 1077-1080, 14 figs. Assembling work. Fourth article.

Clocks

Applications of Magnetic Gears in Electric Clockmaking (Engrenages magnétiques. Application à l'horlogerie électrique), Pierre Seve. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 19, Nov. 4, 1918, pp. 681-683. Mutual action of two disks having magnets attached at regular intervals in their peripheries; disposition to provide magnetic escapement.

Engines, Oil

Quantity Production of Engines at the Skandia Pacific Plant, Geo. N. Somerville. Metal Trades, vol. 9, no. 11, Nov. 1918, pp. 429-434, 10 figs. Operations in various sizes of oil engines.

Lubricator

Manufacturing a Mechanical Lubricator, M. E. Hoag. Am. Mach., vol. 49, no. 26, Dec. 26, 1918, and vol. 50, no. 1, Jan. 2, 1919, pp. 1183-1185 and 23-26, 18 figs.

Plates

See Rolling Mills below.

Quarrying

Rock Quarrying for Cement Manufacture, Oliver Bowles. Department of Interior, Bur. of Mines, bul. 160, min. technology 22, 160 pp., 31 figs. Chief types of cement; growth of cement industry in U. S.; character of raw materials used; quarrying method and equipment with special reference to drilling and blasting; rock mining and prospecting.

Radiators

Building Radiators for Automobiles and Other Purposes, Ellsworth Sheldon. Am. Mach., vol. 49, no. 26, Dec. 26, 1918, pp. 1165-1169, 18 figs. Description of certain processes involved in manufacture of cellular type of radiator.

Rolling Mills

Design of Rolls for Making Ship and Boiler Plates, S. W. Staniford. Machy., vol. 25, no. 5, Jan. 1919, pp. 396-400, 1 fig. Rolling-mill practice; drafts of slabbing and plate-mill rolls; universal mill; surface speed of rolls, rolling tin plate.

The Liberty Mill of the Carnegie Steel Company, Charles A. Menk and F. L. Hunt. Elec. Jl., vol. 15, no. 12, Dec. 1, 1918, pp. 483-489, 18 figs. Layout of buildings and equipment of completely electrically-driven plate mill.

Valley Company Now Rolls Plates. Iron Trade Rev., vol. 63, no. 25, Dec. 19, 1918, pp. 1403-1406, 3 figs. Operation and details of electrically-driven steel plant with annual capacity of 350,000 tons.

Selecting Proper Size Mill Rolls, F. Johnson. Iron Trade Rev., vol. 63, no. 26, Dec. 26, 1918, pp. 1466-1468, 7 figs. Outline of relative advantages obtained by using rolls of small or large diameter for effecting a given reduction; effect of cold-working on physical properties of various metals. From paper before Birmingham Metallurgical Soc., England.

A New Departure in Rolling Mills. Iron Age, vol. 103, no. 1, Jan. 2, 1919, pp. 41-44, 6 figs. Neither lifting tables nor reversing drive employed; design developed by Mackintosh, Hemphill & Co.

Lukens Plate Mill is Largest in the World. Iron Age, vol. 103, no. 1, Jan. 2, 1919, pp. 56-59, 5 figs. Description of the mill.

Brier Hill Steel Co.'s New Plate Mill. Iron Age, vol. 102, no. 25, Dec. 19, 1918, pp. 1521-1524, 6 figs. World's largest mill building; houses and 84- and 132-in. units; power entirely electric; boiler plant dispensed with.

Blooming Mill Now Rolling Plates. Iron Trade Rev., vol. 63, no. 23, Dec. 5, 1918, pp.

Stoker Service

MURPHY FURNACES — RILEY STOKERS
R. SANFORD RILEY, PRESIDENT
SANFORD RILEY STOKER CO. WORCESTER, MASS. — MURPHY IRON WORKS DETROIT, MICH.

1005 MORGAN BLDG., BUFFALO, N.Y.
THE MURPHY AUTOMATIC FURNACE MURPHY IRON WORKS DETROIT, MICH.

When you need legal advice you consult a lawyer.

When you need advice on combustion problems why nct consult a combustion engineer?

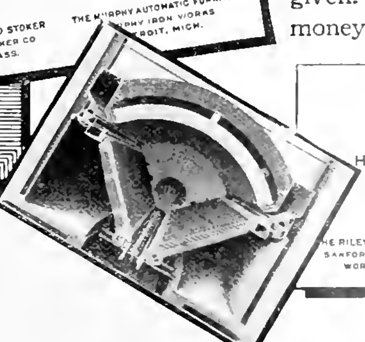
Selection of furnace equipment is a science in itself. Too many have found this to be true at the expense of much time, money and materials.

Replacements are costly. They typify questionable engineering. When you realize that a large percentage of our business is for replacements, then you grasp the significance of having an expert in the first place prescribe the equipment most suitable for your plant.

The *combination* of the sales work of the Sanford Riley Stoker Company and the Murphy Iron Works enables us to unite the efforts and experience of leading combustion experts.

Located at many central points, these engineers stand ready to give constructive service regarding the operation of present equipment as well as making recommendations on new equipment.

Get in touch with our representatives in your territory. They are your councillors. Their services are cheerfully and freely given. Let them save you time, money, men and fuel.



HARRY E OSGOOD, DISTRICT MANAGER
201 DEVONSHIRE STREET, BOSTON, MASS.

TRADE MARK Rx REGISTERED

1285-1288, 4 figs. Account of rebuilding of mill, originally designed for breaking down ingots, to aid rapid transformation from shell steel to peace-time commercial product.

Sawmills

Small Sawmills: Their Equipment, Construction, and Operation, Daniel F. Seerey. U. S. Department of Agriculture, bul. 718, Dec. 17, 1918, 68 pp. Suggestions to portable sawmill operators regarding methods of organization, milling, and lodging which have been proved by experience to give the best results. Written particularly for operators in National Forest timber.

Shell and Ivory Articles

Making Shell Buckles and Brooches, Robert Mawson. Am. Mach., vol. 50, no. 1, Jan. 2, 1919, pp. 20-22. 13 figs. Making of buckles and brooches from shells and ivory performed as far as possible on machines, but some operations are done by hand.

Shovels

Shovels Made Out of Old Locomotive Tires, W. S. Standiford. Can. Machy., vol. 20, no. 25, Dec. 1918, pp. 693-695, 3 figs. Description of manufacturing process.

Tanks, Pressure

Tables for the Design of Pressure Tanks, John A. Cole. Boiler Maker, vol. 18, no. 12, Dec. 1918, pp. 349-351. Specifications for cylindrical pressure tanks; single-riveted lap girth seams, for use when girth and longitudinal seams are the same size; safe working pressures for cylindrical tanks of various diameters; safe working pressures on convex and dished heads.

Tractor

Manufacturing of Farm Tractor, M. E. Hoag. Am. Mach., vol. 49, no. 25, Dec. 19, 1918, pp. 1135-1137. Description of shop arrangement of Moline Plow Co.

MECHANICS

Balancing

Dynamic and Static Balancing, Edward K. Hammond. Machy., vol. 25, nos. 4 and 5, Dec. 1918 and Jan. 1919, pp. 285-292 and 422-426, 26 figs. Two articles explaining conditions which must be fulfilled in balancing machine members, and methods of conducting work.

Stress Theory

The Specification of Stress, Part V, R. F. Gwyther. Memoirs & Proc. Manchester Literary & Phil. Soc., vol. 62, part 1, Aug. 7, 1918, pp. 1-11. Formal solution of elastic stress equations; theory of displacements of materials bodies as consequence of stress; results of hypothesis that nine elements of stress may be functions of nine first differential coefficients of components of some vector; fundamental equations estimating forces causing rate of change of momentum and expression of corresponding rate of change of momentum.

Vibration

Vibration: Mechanical, Musical and Electrical, Edwin H. Barton. Sci. Am. Supp., vol. 87, no. 2244, Jan. 4, 1919, p. 5. Analogies and experimental verification of laws governing vibratory motion. Discourse delivered at Royal Instn. From Engineering.

MOTOR-CAR ENGINEERING

Acceleration Determined by Mechanical Differentiometer

Automobile Performance Analyzed by Mechanical Differentiation, Armin Elmendorf. Automotive Indus., vol. 40, no. 1, Jan. 2, 1919, pp. 11-16, 17 figs. Determination of acceleration from time and distance observations by means of mechanical differentiometer.

Carburetors

Carburetor Adjustments of Twenty Leading Automobiles, George H. Murphy. Am. Blacksmith, vol. 17, no. 12, Sept. 1918, pp. 301-303, 9 figs. Instructions for making adjustments. (To be concluded.)

Design

Post-War Chassis. Automobile Engr., vol. 8, nos. 120 and 121, Nov. and Dec. 1918, pp. 304-305 and 339-340. Nov. 1918: Possible effects of aircraft engine experience and other factors bearing upon design. Pistons; valve position and actuation; valves. Dec. 1918. Valve springs; valve rockers; connecting rods; crankshafts; lubrication.

Analysis of Gas and Gasoline High-Speed Engine Design, Harry R. Ricardo. Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 673-677. Groups of mechanical losses depend upon form of pipe work; volumetric efficiency and piston design. Second article.

Differentials

The Allen Self-Locking Differential. Automotive Indus., vol. 39, no 26, Dec. 26, 1918, p. 1099, 2 figs. Device embodying reversible ratchet principle. Drive on curves is through inner wheel.

Engines

Used Airplane Engines for Automobile Installation, Frank F. Tenney. Automotive Eng., vol. 3, no. 10, Dec. 1918, pp. 457 and 463. Why engines which have outlived their usefulness in air service may still be of service for other uses.

Exports

Export Opportunities for Automotive Products, 11. Automotive Eng., vol. 3, no. 10, Dec. 1918, pp. 454-456. Export of American combustion engine from 1914 to 1917; motor boats and marine machinery in Siam; demand for motor boats in Denmark; high fuel limits in South America; market tractors in Cuba, tractors in farming sections of Wales. (Continuation of serial.)

Cultivating Japanese Automotive Field (III), Tom O. Jones. Automotive Indus., vol. 39, no. 23, Dec. 5, 1918, pp. 970-971. Types of automobiles desired; equipment and finish; automobile building in Japan. (To be continued.)

France

The Automobile after the War, Georges Cote. Automotive Indus., vol. 39, no. 25, Dec. 19, 1918, pp. 1057-1058 and 1075. Views and suggestions to automobile manufacturers of France as to means and methods of meeting reconstruction problems and foreign competition.

Fuels

Benzol Superior to Gasoline as Auto Fuel. Gas Age, vol. 42, no. 12, Dec. 16, 1918, pp. 548-550, 2 figs. Result of comparative tests made by Automobile Club of America; 90 per cent benzol said to give higher brake hp. at less fuel consumption by the motor.

Liberty Fuel

Liberty Fuel, A Chemical Marvel, E. W. Roberts. Gas Eng., vol. 21, no. 1, Jan. 1919, pp. 1-4, 8 figs. Description of fuel with report of U. S. Government tests.

Properties of Liberty Fuel and Results of Economy Tests. Power, vol. 49, no. 1, Jan. 7, 1919, pp. 9, 2 figs. Particulars as to nature and characteristics of new fuel.

Headlights

Headlamp Glare. Jl. Soc. Automotive Engrs., vol. 3, no. 6, Dec. 1918, pp. 364-366. Account of work done and bases followed by committee of Illum. Eng. Soc. in preparation of headlight specifications.

Manufacturing Problems

Why So Many Motor Models? George F. Crouch. Motor Boat, vol. 15, no. 23, Dec. 10, 1918, pp. 18-20, 3 figs. Observes that concentration by manufacturer on fewer sizes would mean better motors, better service and lower cost.

Radiators

Principles of Tractor Radiator Design, E. Goldberger. Automotive Indus., vol. 38, no. 24, Dec. 12, 1918, pp. 1000-1003, 3 figs. Equations showing dependence of radiator capacity on temperatures, rates of flow and inherent characteristics; advantages of thermosiphon circulation in tractor work.

Steam Vehicles

A New British Coke-Fired Steam Commercial Vehicle. Automotive Indus., vol. 39, no. 22, Nov. 28, 1918, pp. 919-922, 6 figs. Three-ton chassis having automatic control of steam-generating functions and manual control of devices arranged as on a gasoline vehicle.

Suspension

Houdaille Brings Out Adjustable Car Suspension, F. W. Bradley. Automotive Indus., vol. 38, no. 24, Dec. 12, 1918, pp. 1004-1005, 2 figs. Device which permits moving points of attachment of springs to car frame.

Tractors

S. W. H. Tractor a New Cleveland Product. Automotive Indus., vol. 39, no. 26, Dec. 26, 1918, pp. 1085-1088, 5 figs. Three-plow machine with pressed-steel semi-frame bolted to front end of transmission housing; engine and transmission independent.

The Auto Tiller, a Two-Horse Team Replacement Unit. Automotive Eng., vol. 3, no. 10, Dec. 1918, pp. 473-477, 5 figs. Field of utility and mechanical details of motor tractor for farm work operated by one man from a fixed position.

Trucks

Regulation of Speed, Weight, Width and Height of Motor Trucks Discussed, George M. Graham. Eng. News-Rec., vol. 81, no. 25, Dec. 19, 1918, pp. 1109-1112. Regulation, while necessary, should not restrict expansion of motor truck; table of proposed dimensions, speeds, weights, and fees presented.

Double Reduction Gear Drive for Heavy Duty Trucks. Am. Blacksmith, vol. 18, no. 2, Nov. 1918, pp. 32-33. Operation of drive in new 3- and 5-ton White models.

Wheel

An Elastic Wheel (La roue élastique I. D.). Génie Civil, vol. 73, no. 20, Nov. 16, 1918, pp. 393-394, 2 figs. Design which by means of helical springs attached to rim permits tangential effort on wheel to be distributed over a number of contact points of spring.

See also MECHANICAL ENGINEERING, Mechanical Processes (Radiators); Internal-Combustion Engines (Buckeye Barrett Engine); Machine Shop (Repair Work).

PIPE

See MECHANICAL ENGINEERING, Corrosion (Pipe).

POWER GENERATION

Exhaust Steam

Utilization of Exhaust Steam in Collieries for the Generation of Electrical Energy (Considérations sur l'utilisation des vapeurs d'échappement dans les houillères en vue de la production d'énergie électrique), A. Barjou. Industrie Electrique, year 27, nos. 621, 623, 627, 631 and 634, May 10, June 10, Aug. 10, Oct. 10 and Nov. 25, 1918, pp. 166-171, 212-217, 287,293, 373-379 and 425-430. 26 figs. May 10: theoretical aspect of problem. June 10: systems of regulating exhaust steam. Aug. 10: utilization of exhaust steam in low-pressure turbines. Oct. 10: Westinghouse Leblanc system of condensation. Nov. 25: Brequet-Delaporte condenser.

Tides

Tides as a Source of Mechanical Power (Etude sur l'utilization des marées pour la production de la force motrice), F. Maynard. Revue Générale de l'Electricité, vol. 4, nos. 19, 20 and 21, Nov. 9, 16 and 23, 1918, pp. 697-715, 749-762 and 793-802, 14 figs. Brief description of 87 patents granted in France concerning devices for utilization of tidal energy and analyses of their practical values. (To be continued.)

POWER PLANTS

Boiler Water

Control of Concentrated Boiler Water is Essential, Hartley Lell. Smith. Elec. Ry. Jl., vol. 52, no. 25, Dec. 21, 1918, pp. 1087-1091, 1 fig. Methods used for control of concentration in boilers; how ratio of concentration from feedwater to boiler water is determined; calculation of boiler concentration control charts.

Coal Economy

Coal Economy in a Small Steam Generating Station. Elec. Rec., vol. 24, no. 6, Dec. 1918, pp. 27-28, 3 figs. Results secured in 290-kw. plant given as example of coal saving.

Flue-Gas Analysis

Controlling Efficiency of Combustion, E. A. Uehling. Power, vol. 48, no. 26, Dec. 24, 1918, pp. 921-923. Use of flue-gas analysis for controlling combustion.

Furnace Indicating Instruments

Meters and Gages in Boiler Operation, E. A. Uehling. Power, vol. 48, no. 24, Dec. 10, 1918, pp. 842-844. Use of meters and gages in diagnosing condition of furnace.

Hand Firing

Power Plant Management: Hand Firing, Robert June. Power House, vol. 11, no. 11, Nov. 1918, pp. 315-317, 3 figs. Standard practice; proper combustion conditions; thickness of fire; minimization of smoke.

Individual Plants

Steam-Generating Equipment of Mark Plant, Gordon Fox and F. E. Grenley. Power Plant Eng., vol. 22, no. 24, Dec. 15, 1918, pp. 981-984, 3 figs. Description of certain features of new plant of Steel & Tube Co. of America.

Power Plants in 1918

Review of the Year in the Power Field. Power, vol. 49, no. 1, Jan. 7, 1919, pp. 2-8. What has been new and of especial interest during 1918.

Scale in Boilers

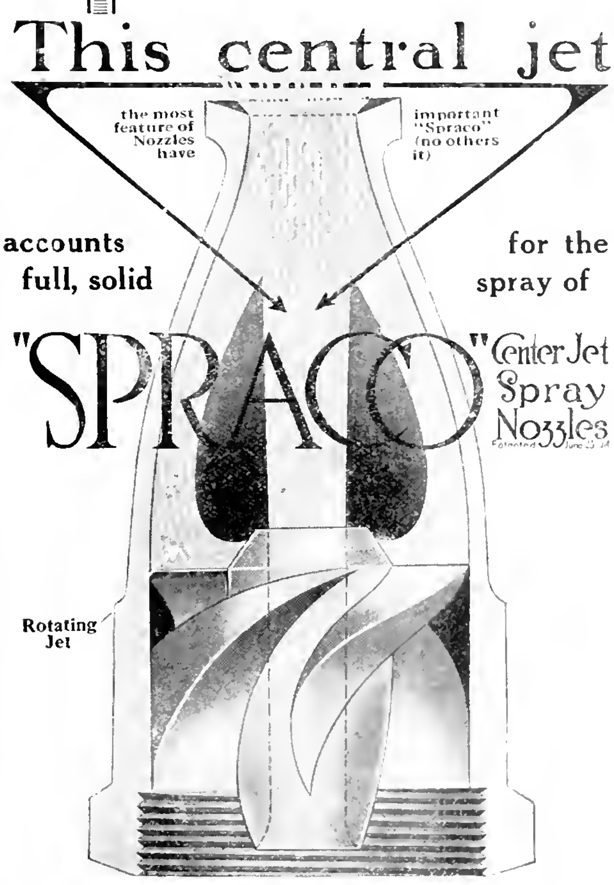
Scale in Water-Tube Boilers. Monthly Jl. Utah Soc. Engrs., vol. 4, no. 9, Sept 1918, pp. 175-176. Results of cleaning a 400-hp. Babcock & Wilcox boiler after operating it for six months, with table indicating the amount of scale taken from each of its 14 sections.

Transmission Losses

Wasting Power in the Using, L. W. Alwyn-Schmidt. Power Plant Eng., vol. 22, no. 24, Dec. 15, 1918, pp. 984-987. Transmission losses, waste of power at machine and methods suggested for overcoming them.

SPRACO

Spraco Cooling System



The war is won, but the necessity for conservation is as great as ever. The whole world needs coal—we must save every pound possible. Spraco Equipment, which helped to put many plants on a basis of wartime efficiency, is ready for the work of reconstruction.

The Spraco Cooling System (with Spraco Center Jet Nozzle) saves fuel and cuts operating costs. Under ordinary conditions it will cool condensing water sufficiently to insure an average vacuum of 27 inches or better, throughout the year. And compared to a cooling tower the Spraco System costs much less to install, about one-half as much to operate and practically nothing to maintain.

Our engineers are at your service—ready to submit drawings, specifications and estimates covering an installation in your plant. A word from you will bring full details.

SPRAY ENGINEERING CO.

93 Federal St., - Boston, Mass.

Engineers Manufacturers

SEE OUR DATA IN 1918 A.S.M.E. CONDENSED CATALOGUES OF MECHANICAL EQUIPMENT

Turbo-Generator Plants

Operating Methods That Increase Economy. C. F. Hirshfeld and C. L. Karr. Elec. World, vol. 72, no. 24, Dec. 14, 1918, pp. 1120-1121, 2 figs. Apply to turbo-generator plants; distribution of loads on boilers and turbines and economical operation of auxiliaries discussed.

Economic Operation of Steam Turbo-Electric Stations. T. C. Hirshfeld and C. L. Karr. Elec. Rev., vol. 73, nos. 23 and 24, Dec. 7 and 14, 1918, pp. 886-890 and 923-928, 5 figs. Bureau of Mines Technical Paper discussing fuel-economy factors, load, distribution between units, boiler room and auxiliaries operation.

Waste Heat

Waste Heat for Steam Generation. Thomas B. Mackenzie. Engineering, vol. 106, no. 2759, Nov. 15, 1918, pp. 567-569, 2 figs. Utilization of waste heat from open-hearth furnaces for generation of steam. Paper before Iron & Steel Inst., Sept. 1918.

PRODUCER GAS

Kiln, Gas-Fired

Heat Balance on a Producer-Gas Fired Chamber Kiln. R. K. Hursh. Jl. Am. Ceramic Soc., vol. 1, no. 8, Aug. 1918, pp. 567-577, 1 fig. Data based on tests of a kiln of 16 chambers, each holding 50,000 standard-sized brick, and on three 6-ft. water-sealed gas producers of the pressure type.

Open-Hearth Furnaces

Waste Heat from Open Hearth Furnaces. Thomas B. Mackenzie. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 488-492, 3 figs. Analysis of producer gas supplied to furnace; theoretical principles governing operation of waste-heat boilers; suggestions concerning layout of plant and boiler setting. Paper before British Iron & Steel Inst. (Concluded.)

Wood

The Production of Power-Gas from Wood. Leslie B. Williams. Min. Mag., vol. 19, no. 5, Nov. 1918, pp. 246-250. Discusses composition of power gas from wood and methods of obtaining largest amounts of most effective components.

PUMPS

Motor-Driven Pumps

High Efficiencies Shown by Motor-Driven Water Works Pumps at St. Paul, Minn. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 202-204, 2 figs. Results obtained from tests of two 12-in. centrifugal pumps.

REFRACTORIES

Classification

Refractories. Clay-Worker, vol. 70, no. 6, Dec. 1918, pp. 504-505. Reasons for classification into acid, basic and neutral; construction, effectiveness and uses of each of these classes; properties of some refractory clays.

Firebrick

How Slag Temperatures Affect Firebrick. Raymond M. Howe. Iron Trade Rev., vol. 63, no. 23, Dec. 5, 1918, pp. 1288-1289. Penetration of slag into brick was determined after allowing bricks, which were previously heated to required temperature, to retain in cavity 35 grams of slag for 2 hrs.; tables given for various temperatures. Paper before Refractories Mfrs. Assn. Also Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 484-485.

Silica

Silica Refractories. Donald W. Ross. Jl. Am. Ceramic Soc., vol. 1, no. 7, July 1918, pp. 477-499, 6 figs. and (discussion) pp. 499-501. Experimental data on raw materials, manufacture and burning of silica brick, and properties of burned ware.

REFRIGERATION

Ammonia

What Becomes of the Ammonia in Refrigerating Systems? George L. Reuschline. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 3, Nov. 1918, pp. 161-167. Production of ammonia from normal sources; amount used in ice and refrigerating plants; actual needs and unavoidable losses; actual ammonia loss per ton of ice made; avoidable losses and how to stop them; purging; piston-rod leakage; bonus system.

Ammonia, Compression System

The Ammonia Compression Refrigerating System XXV. W. S Doan. Refrig. World, vol. 53, no. 12, Dec. 1918, pp. 33-34, 1 fig. Testing of lubricating oil; petroleum oils; necessary quantity to feed bearings. (To be continued.)

Ammonia Piping

Discussion of the Topic—Size of and Proper Vapor Velocity in Ammonia Suction and Discharge Mains. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 2, Sept. 1918, pp. 120-124, 1 fig. Discussion at Milwaukee meeting.

CO_2 Machine

The Carbonic Anhydride Refrigerating Machine. Peter Neff. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 3, Nov. 1918, pp. 153-156. Items of design requiring research before a CO_2 machine can be developed as successfully as one of the ammonia type.

Forecooling

Discussion of the Topic Advantages of Forecooling Liquid Ammonia Between Receiver and Expansion Valve with Coldest Water Available. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 2, Sept. 1918, pp. 125-130. Discussion at annual meeting, New York.

Household Refrigerating Machine

The Household Refrigerating Machine. John E. Starr. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 3, Nov. 1918, pp. 157-160. Attributes difficulty of designing commercial type of small compression machine to leakage at stuffing box, small quantity of liquid circulated per minute and gradual projection of lubricant from high-pressure to low-pressure side.

Ice Manufacture

Ice Plant Investments. George. E. Wells. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 3, Nov. 1918, pp. 145-152. Detailed ice-manufacturing costs in 1915 of 20 southwestern ice plants using Corliss steam engines.

Power and Labor Requirements of Detroit Type Ice Plant. Donald Cole. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 2, Sept. 1918, pp. 110-115 and (discussion) pp. 115-119. Operation of electrically driven raw-water plant, low-pressure, drop-pipe system having in conjunction an ice storage house holding full output of thirty to one hundred days.

Motor Driven Raw Water Ice Plant. George E. Chamberlin. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 2, Sept. 1918, pp. 87-109, 11 figs. Description of electrically driven high-pressure plant making 120 tons of ice per day.

Low-Temperature Compression System

The Low-Temperature Compression System in Practice. H. Sloan. Power, vol. 48, no. 25, Dec. 17, 1918, pp. 896-987, 2 figs. From paper before Am. Soc. of Refrig. Engrs., Milwaukee.

RESEARCH

British

National Laboratory for Industrial Research. Richard T. Glazebrook. Contract Rec., vol. 32, no. 47, Nov. 20, 1918, pp. 924-926. Need of special laboratories for research work; research for trade associations; study of industrial problems in central laboratory. From lecture delivered at Royal Instn.

Science and the Future. A. A. Campbell Swinton. Machy. Market, no. 944, Dec. 6, 1918, pp. 19-20. From address to Roy. Soc. Arts.

National Research Council, U. S.

The Engineering Work of the National Research Council. Henry M. Howe. Bul. Am. Inst. Min. Engrs., no. 144, Dec. 1918, pp. 1715-1719. Purpose, status in October, 1918, and character of researches on pyrometry and electric welding.

STANDARDS AND STANDARDIZATION

Engine-Testing Forms

Standard Engine Testing Forms. Jl. Soc. Automobile Engrs., vol. 3, no. 6, Dec. 1918, pp. 378-381, 3 figs. Four sheets: one giving rules and direction for use of forms and three providing means for giving information regarding engine conditions of test and plotting curves of results.

Gasoline

Government Standard Gasoline and Oil Specifications. Jl. Soc. Automotive Engrs., vol. 3, no. 6, Dec. 1918, pp. 405-406. Specifications for aviation gasoline, motor gasoline, and fuel, gas and bunker oils, adopted by Committee on Standardization of Petroleum Specifications.

Oils, Illuminating

Specifications for Illuminating Oils. Oil & Gas Jl., vol. 17, no. 31, Jan. 3, 1919, pp. 50-52. Methods of test and specifications adopted by Committee on Standardization of Petroleum Specifications. Rules were drafted with view to allow making of products from any satisfactory crude petroleum.

STEAM ENGINEERING

Boilers

Modern Boilers (Les chaudières modernes). L. Conge. Revue Générale de l'Electricité, vol. 4, no. 19, Nov. 9, 1918, pp. 715-718, 11 figs. Several French and American types are considered as usable in large central turbo-electric stations.

Feeding and Circulating the Water in Steam Boilers. John Watson. Trans. Inst. Marine Engrs., vol. 30, no. 239, Nov. 1918, pp. 225-246 and (discussion) pp. 246-264, 7 figs. Historical account of schemes evolved and experimental work undertaken; analysis of present practices in the various types of boilers; effect of mixing hot boiler water with incoming feed in proportions up to 200 per cent. boiler water.

Mechanical Department Circular No. 11, U. S. Ry. Administration. Frank McManamy. Ry. Jl., vol. 25, no. 1, Jan. 1919, pp. 21-22, 1 fig. Rules and instructions for inspection and testing of stationary boilers.

How to Design and Lay Out a Boiler—II. William C. Strott. Boiler Maker, vol. 18, no. 12, Dec. 1918, pp. 353-354, 5 figs. Calculation of proper tube expansion; purpose of beading; use of scant tube lengths; figuring "line-up." (To be continued.)

Condensers

Keeping Up Condenser Performance. Hartley LeH. Smith. Power, vol. 48, no. 25, Dec. 17, 1918, pp. 868-870, 4 figs. How to determine economy which should be obtained and how to correct causes of low vacuum.

Steam Pressure, High

High Steam Pressure and Superheat. Eskil Berg. Power, vol. 48, no. 24, Dec. 10, 1918, pp. 832-835, 3 figs. From a paper before joint meeting of Western Soc. of Engrs., Chicago Section of Am. Soc. of Mech. Engrs. and Am. Inst. of Elec. Engrs.

Turbines

Steam Turbines for Natural Steam. Power Plant Eng., vol. 22, no. 24, Dec. 15, 1918, pp. 990-993, 7 figs. Power plant at Larderello, Italy, operating large turbine units with natural steam taken from crevices and fissures in ground.

Turbine Engines for Cargo Vessels. Marine Rev., vol. 49, no. 1, Jan. 1919, pp. 31-34, 6 figs. Mechanical features of the geared drives.

Steam Turbine Progress and Possibilities. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 481-483, 5 figs. Higher boiler pressures; intermediate steam reheating in large multiple-cylinder machines; feedwater heating; use of economizer.

The Historical Development of Steam Turbine (I). Power House, vol. 11, no. 11, Nov. 1918, pp. 311-314, 10 figs. Growth in capacity and in size of individual units during last 30 years. (To be continued.)

Valves, Balanced Slide

Balanced Slide Valve for Andrews-Cameron Steam Engine (Tiroir équilibré pour machine à vapeur système Andrews et Cameron). Génie Civil, vol. 73, no. 17, Oct. 26, 1918, pp. 333-334, 8 figs. Description of two types, one with two and other with three ports.

See also MECHANICAL ENGINEERING, Motor-Car Engineering (Steam Vehicles).

THERMODYNAMICS

Heat Transmission

Heat Transfer Tests of Building Materials. L. M. Arkley. Jl. Eng. Inst. Can., vol. 1, no. 8, Dec. 1918, pp. 386-393, 6 figs. Account of tests (1) to determine selection of proper materials to be used in buildings, (2) to determine effect on transfer of heat through a 12-in. hollow tile wall of laying it up, first with hollow spaces horizontal, and second with hollow spaces vertical and directly over each other, (3) to investigate heat-insulating qualities of a number of materials suitable for refrigerating rooms including built-up walls, cork walls, and ordinary building papers.

New Heat Transmission Tables. William R. Jones. Heat. & Vent. Mag., vol. 15, no. 12, Dec., 1918, pp. 36-40. Third series of tables.

WELDING

Aluminum

How to Use a "Chill" on Aluminum Welding. David Baxter. Jl. Acetylene Welding, vol. 20, no. 6, Dec. 1918, pp. 280-282, 3 figs. Method of backing up hole in aluminum crankcase with piece of heavy galvanized iron and welding across to fill hole with aluminum, the iron acting as a sort of chill.

Arc-Welding Tool

Improved Arc Welding Tool. Aerial Age, vol. 8, no. 12, Dec. 2, 1918, pp. 619-634, 2 figs. Designed to make operation of changing electrodes definite, to permit any amount of pull when electrode freezes to work and capable of operating for voluntary release.

Electric Welding

Comparisons of Processes of Electric Butt Welding. J. B. Clapper. Boiler Maker, vol. 18, no. 12, Dec. 1918, pp. 345-346. Operations

in butt welding; transformer control; strength of butt weld; application of point and spot welding; use of resistance process.

Modern Welding by Use of Electricity. Elec. Rev., vol. 73, no. 25, Dec. 21, 1918, pp. 959-962, 3 figs. Principles of electric arc and spot welding; advantages; methods of application; recent developments; extent of field.

Some Recent Developments in Machines for Electric Spot Welding as a Substitute for Riveting, J. M. Weed. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 928-934, 9 figs. Writer claims his experiments have demonstrated that the thickness of parts to be welded is governed by capacity of apparatus available for doing the work.

Electric Welding—A New Industry, H. A. Hornor. Contract Rec., vol. 32, no. 47, Nov. 20, 1918, pp. 931-934. Status of industry; uses of alternating current; methods of welding and of testing a joint; developments. Paper before Am. Inst. Elec. Engrs.

Comparative Characteristics of Arc Welders, J. F. Lincoln. Elec. World, vol. 72, no. 24, Dec. 14, 1918, pp. 1119-1120. Discussion to bring out comparative advantages and costs of a. c. and d. c. welders.

Features of Arc Welding Development, O. A. Kenyon. Elec. Rev., vol. 73, no. 25, Dec. 21, 1918, pp. 963-965, 2 figs. Control of welding heat; selection of kind and size of electrodes; kinds of joints and their characteristics; systematic planning of welding method to be used.

The Constant-Energy Arc-Welding Set, P. O. Noble. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 938-940, 6 figs. Type of equipment designed to facilitate maintenance of a short arc and to make it difficult to continue a long one.

Electric Welding at the Erie Works, General Electric Company, H. Lemp and J. R. Brown. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 915-918, 12 figs. Applications of process to welding saws, butt-welding high-speed steel to shank of machine steel in manufacture of machine tools, and various other mechanical purposes.

A Review of Electric Arc Welding, John A. Seede. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 881-886, 10 figs. Evaluation of present practice, with special consideration of carbon electrode welding, metallic electrode welding, electrodes, fluxes, holders, a. c. arc welding, automatic welding and apparatus employed.

Inspection of Welds

Inspection of Electric Welds, O. H. Escholz. Power, vol. 48, no. 25, Dec. 17, 1918, pp. 872-873, 3 figs. Describes various tests and their efficiencies.

Inspecting Metallic Electrode Arc Welds, O. S. Escholz. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 448-450, 4 figs. Comments on significance and value of visual inspection, adhesion of deposit, penetration and electrical tests.

Joints

Lloyd's Experiments on Electrically Welded Joints, H. Jasper Cox. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 864-870, 16 figs. Results concerning modulus of elasticity, approximate elastic limit, ultimate strength, ultimate elongation, alternating stresses, chemical and microscopic analysis, and strength of welds.

Non-Ferrous Metals

The Butt Welding of Some Non-Ferrous Metals, E. F. Collins and W. Jacob. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 958-961, 5 figs. Describes process said to be outcome of search for satisfactory method of connecting end rings to rotor bars of induction motor.

Oxidation

The Welding of Iron and Steel, W. H. Cathcart. Iron Age, vol. 102, no. 26, Dec. 26, 1918, pp. 1578-1583, 10 figs. Principles governing smithy and forge; effect of oxidation; use of a flux; annealing essential; conditions to be fulfilled. From article in Apr., 1918, issue of Jl. of West of Scotland Iron and Steel Inst., Glasgow.

Oxy-Acetylene Welding

Oxy-Acetylene Pipe Welding and Cutting. Gas Age, vol. 42, no. 12, Dec. 16, 1918, pp. 515-516, 5 figs. Practical suggestions on manipulation of blowpipe. (Continuation of serial.)

Handling Acetylene Welding Outfits, E. Wanamaker. Ry. Rev., vol. 63, no. 25, Dec. 21, 1918, pp. 869-871. Discussion of acetylene and oxygen gases and instructions for handling outfits in shops. Paper before Ry. Fire Prevention Assn., Chicago.

Research

Research in Spot Welding of Heavy Plates, W. L. Merrill. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 919-922, 7 figs. Record of experiments with specially built welding machine of 36 tons pressure capacity and 100,000 amperes current capacity, showing probability that new field of application for spot welding will be developed.

Structure of Iron

Microstructure of Iron Deposited by Electric Arc Welding, George F. Comstock. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 43-50, 10 figs. From microscopic examination of a weld writer concludes that pale crystals typical of steel fusion welds are not cementite or martensite or any similar carbide product, but probably nitride of iron. Discussion of S. W. Miller's paper. (Bul. A. I. M. E., Feb.-May, 1918.)

A Study of the Joining of Metals, J. A. Capp. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 947-956, 36 figs. Microscopic study of welds made (1) with high current applied for long periods, (2) smaller current applied for shorter time, and (3) current just large enough to procure welding temperature when applied for minimum time; made to determine best practice in making butt welds by Thompson electric welding machine.

The Metallurgy of the Arc Weld, W. E. Ruder. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 941-946, 15 figs. Notes based on microscopical examination of crystal structure, gas holes, slag inclusions, impurities, and composition.

Tank Manufacture

Electric Arc Welding in Tank Construction, R. E. Wagner. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 899-911, 35 figs. Qualifications of successful operator; value of intelligent study of work in hand and its preparation for welding; application of arc welding to tank construction; tabular data for determining cost of process.

Welded Seams

Welded Seams Correct Faults in Converters. Boiler Maker vol. 18, no. 12, Dec. 1918, pp. 347-348, 6 figs. Experiments on welded-type heaters; difficulties in welding materials of varying thicknesses; automatic cutting machine. From Jl. Acetylene Welding.

Welding

Principles and Practices of Fusion Welding, S. W. Miller. Am. Soc. Refrig. Engrs. Jl., vol. 5, no. 3, Nov. 1918, pp. 168-215, 83 figs. Differences between various systems; principles of successful welding; composition of weld; testing welds; welding practices and materials; metallurgy and heat treatment of welds; variety of welds.

See also ELECTRICAL ENGINEERING, *Transformers, Converters, Frequency Changers (Welding, Transformers for)*; MARINE ENGINEERING, *Yards (Welding)*; RAILROAD ENGINEERING, *Shops (Welding)*.

VARIA

Metric System

Reflexions on the Arguments For and Against the Metric System (Reflexions sur les pour et les contre du système métrique), Ch. Ed. Guillaume. Industrie Electrique, year 27, no. 624, June 25, 1918, pp. 225-227. Question of fundamental units; decimalization; possible adoption by Anglo-Saxon nations; arguments based on present situation. Remarks on Atkinson's communication to Instn. Elec. Engrs.

Opportunities for Engineers

Broader Opportunities for the Engineer, Charles T. Main. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 6-11. Fields of activity opened to engineering societies and individual engineers in consequence of technical and social opportunities which have been created with the advent of world peace. Presidential address delivered at annual meeting of the Society.

Packing, Machinery

The Problem of Packing. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 257-262, 6 figs. Suggestions in regard to packing machinery for home market and export.

Society Engineering

Aims and Organization of the Society, L. C. Marburg. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 12-15. Relations of the mechanical engineer to his work, to the community and other engineers. Report of Committee on Aims and Organization of the Society.

Technical Writing

Obtaining Ideas for Technical Articles, Albert M. Wolf. Wis. Engr., vol. 23, no. 2, Nov. 1918, pp. 40-41. Value of observation and diligent application of mental faculties to gathering technical data.

Electrical Engineering

ELECTROPHYSICS

A. C. Circuits

The Calculation of Alternating Current Circuits, Gordon Kribs. Power House, vol. 11, no. 11, Nov. 1918, pp. 318-321, 2 figs. Tables of constants offered as readily usable in computing size of wire in a. c. 25- and 60-cycle circuits.

Harmonic Analysis

Harmonic Analysis of Alternating Currents by the Resonance Galvanometer (Sur l'analyse harmonique des courants alternatifs par le galvanomètre de résonance), André Blondel. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 20, Nov. 11, 1918, pp. 711-717, 1 fig. Characteristics of method proposed as modification of Pupin's and Armagnat's. Considers (1) non-inductive resistances in circuits of galvanometer, and (2) a circuit having one or several capacities in series.

Spark-Plug Insulators

Resistance of Hot Spark Plug Insulators, R. H. Cunningham. Automotive Indus., vol. 39, no. 22, Nov. 28, 1918, pp. 907-911, 8 figs. Experimental tests to determine loss of resistance at working temperatures; how such loss affects action of plug.

Vapor Arcs

Low-Voltage Arcs in Metallic Vapours, J. C. McLennan. Proc. Phys. Soc., Lond., vol. 31, no. 176, Dec. 15, 1918, pp. 30-48, 6 figs. Repetition of experiments by Millikan and Hebb whose results writer believes to be in conflict with quantum theory. Results showed that quantum relation holds good with moderately heated incandescent cathodes and a moderate supply of metallic vapor. It was possible to obtain questioned phenomena, however, by increasing temperature of incandescent cathode.

ELECTROCHEMISTRY

Copper Plating

Automatic Copper Plating, Joseph W. Richards. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 27-31, 4 figs. Patented process. Basic principle involved lies in application of plating copper while iron sheet is cold and then melting metal under conditions favorable to formation of plating.

FURNACES

Electric Furnace Improvements During 1918, A. V. Farr. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 20-24, 9 figs. Efforts to increase output; linings, tilting apparatus and cooling; power supply; comparative data.

Electrodes

Electrodes for Electric Furnaces: Their Manufacture, Properties, and Utilization (II), Jean Escard. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 781-792, 37 figs. Form, dimensions, grouping, and composition of electrodes, and their arrangement in the various types of furnaces; life, wear, and protection of electrodes; electrode holders, cooling systems, and methods of attaching connections. Translated from Le Génie Civil.

Industrial Furnaces

Electric Heated Industrial Furnaces, George J. Kirkgasser. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 26-32, 14 figs. Type of furnaces and accessory apparatus used in melting irons, brasses and bronzes in foundries; for heat-treating metal parts; in the manufacture of special alloys; for annealing, hardening and tempering tools; and for determining decalescent and recalescent points in tool steels.

Nitrogen-Fixation Furnaces

Nitrogen Fixation Furnaces, E. Kilburn Scott. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 793-804, 16 figs. Salient points of difference between electric furnaces for fixation of nitrogen and those for metallurgical purposes. Discussion of various features in operation, such as phase balance, starting, losses, electrodes, stabilizing arc, power factor, air supply, preheater, absorption, cooling the gas, and theory of reaction. Abstract of paper before Electrochemical Soc.

Steel Furnaces

The Status of the Electric Steel Industry, Edwin F. Cone. Iron Age, vol. 103, no. 1, Jan. 2, 1919, pp. 60-62. United States still leads in output with 287 furnaces; progress since 1910; furnaces in world's industry probably over 815.

Electric Furnaces for the Production of Steel and Ferro-Alloys, J. O. Seede. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 767-780,

28 figs. Fundamentals of high-grade steel manufacture; author prefers electric furnace to all other types; classification and sketches of important furnaces.

Adds Electric Unit to Melting Equipment. Iron Trade Rev., vol. 63, no. 24, Dec. 12, 1918, pp. 1353-1354, 10 figs. Installation in which power is supplied through bank of two single-phase, 500-kva. transformers connected to a 2300-volt, 3-phase, 60-cycle supply line. Furnace hearth acts as neutral electrode, bottom connection being made to central point on transformer. Arcs are formed independently of one another.

Electric Furnaces in Metallurgy. Elecn., vol. 81, no. 2113, Nov. 15, 1918, pp. 588-590, 7 figs. Description of Héroult furnace.

The Electric Furnace in the Grey Iron Foundry. Can. Foundryman, vol. 9, no. 12, Dec. 1918, pp. 291-292 and 295, 4 figs. Work being done by Bowmanville Foundry Co. Mechanical features and electrical control of furnace.

Electric Furnace Data for Ferro-Tungsten. Robert M. Kenney. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 486-487. Data and description of ferro-tungsten production; smelting of ferberite concentrate; possibilities of making in one single operation ferro-tungsten containing less than one per cent carbon. Paper before Am. Inst. Min. Engrs.

GENERATING STATIONS

Canada

Electric Power Generation in Ontario on Systems of Hydro-Electric Power Commission, Arthur H. Hull. Can. Engr., vol. 35, no. 25, Dec. 19, 1918, pp. 532-533. Details of generation and electrical distribution: Rideau and Niagara systems: Queenstown development. (Concluded.)

Centralization of Power

Wholesale Power, F. P. Royce. Stone & Webster Jl., vol. 23, no. 5, Nov. 1918, pp. 357-360. Conditions favorable to centralization of electric power. Memorandum of statement made at meeting of New England Section of Nat. Elec. Light Assn.

Hydroelectric Stations

Electric Power Generation in Ontario on Systems of Hydro-Electric Power Commission, Arthur H. Hull. Can. Engr., vol. 35, no. 24, Dec. 12, 1918, pp. 520-523. Paper before Toronto Section Am. Inst. Elec. Engrs. Also Elec. News, vol. 27, no. 23, Dec. 1, 1918, pp. 25-29, 1 fig. General plan and particulars of canal development work and power generation.

The Present Status of Hetch Hetchy, Rudolph W. van Norden. Jl. Elec., vol. 41, no. 10, Nov. 15, 1918, pp. 438-443, 8 figs. Survey, scope and present progress of water and power project undertaken by city of San Francisco.

Data Existing in Regard to the Construction of Hydroelectric Power Plants (Sur les données actuelles en matière de construction d'usines hydroélectriques), Denis Eydoux. Annales des Ponts et Chaussées, year 88, vol. 4, no. 18, Jul-Aug. 1918, pp. 7-96, 34 figs. Résumé of theoretical considerations, general equations and present practice, with special reference to groups of French plants in Dauphiné and the arrangement existing between water-courses of the Société Pyrénéene (Toulouse and Tarn) with those of the Société Meridionale (Aude and Hérault). (To be continued.)

Steam-Electric Stations

A Good Instance of Utilization of Italian Products in Argentine (Uno forte impronta dei produttori italiani nell' Argentina). L'Industria, vol. 32, no. 21, Nov. 15, 1918, pp. 638-644, 13 figs. Details and plans of steam-turbine central station distributing 30 million kw-hr. at 7000 volts to five substations. Substation also described.

GENERATORS AND MOTORS

Dynamical Theory

The Dynamical Theory of Electric Engines. Elecn., vol. 81, no. 2114, Nov. 22, 1918, pp. 616-617, 4 figs. Abstracted from 10th Kelvin lecture delivered by L. B. Atkinson before Inst. of Elec. Engrs.

Alternators

High-Frequency Alternators (Les alternateurs à haute fréquence), O. Billeux. Revue Générale de l'Electricité, vol. 4, no. 21, Nov. 23, 1918, pp. 803-805, 5 figs. Principles of these machines, particularly of the Alexanderson type (frequency, 30,000 per sec.), built for experimental purposes.

Generators

Construction and Use of Generators Driven by Waterwheels. Elec. Rec., vol. 24, no. 6, Dec. 1918, pp. 60-66, 24 figs. Important features in both vertical and horizontal types.

Induction Motors

Reconnecting Induction Motors—For Change in the Number of Poles, A. M. Dudley. Power, vol. 49, no. 1, Jan. 7, 1919, pp. 9-14, 15 figs. (Third article.)

Rotors

Turbo-Alternator Rotors: Features of Mechanical Design (II), S. F. Barclay. Power House, vol. 11, no. 11, Nov. 1918, pp. 323-327, 17 figs. Suggested specifications for guidance in purchasing equipment.

Synchronous Motors

Magnetization Curves for Synchronous Motors (Fältkurvor-diagram och magnetiseringskurvor for flerfasiga synkronmaskiner), John Wennerberg. Teknisk Tidskrift, Elektroteknik, vol. 48, no. 11, Nov. 6, 1918, pp. 138-146.

LIGHTING AND LAMP MANUFACTURE

Fixtures

Linking Science and Art in Lighting, M. Luckiesh. Elec. Rev., vol. 73, no. 23, Dec. 7, 1918, pp. 884-885. Suggestions for fixture dealer in demonstrating lighting effects. Third article. (First and second appeared in Elec. Rev. Oct. 5 and Nov. 2.)

Lamps, Manufacture

Methods of Manufacturing Incandescent Lamps, H. M. Robins. Wis Engr., vol. 23, no. 3, Dec. 1918, pp. 67-76, 6 figs. Description of required operations with reference to advantageous working conditions of manufacturing establishments.

Light Generation and Distribution

Light, Electricity and the Shop, C. E. Clewell. Am. Mach., vol. 49, no. 24, Dec. 12, 1918, pp. 1061-1065, 10 figs. From coal pile to machine tool and lamp, losses are considered.

MEASUREMENTS AND TESTS

Loader

The Loader, Ross B. Mateer. Jl. Elec., vol. 41, no. 12, Dec. 15, 1918, p. 553, 4 figs. Suggests composite symbol to indicate load center, density and character of load served.

Meters

Three-Wire D-5 Meters. Jl. Elec., vol. 41, no. 10, Nov. 15, 1918, pp. 474-475. Wiring diagram and features of watthour meter consisting of two- and three-wire elements placed side by side in common base and registering on common recording train so that sum of revolutions of both elements will be added and indicated on dial.

Power-Factor Indicators

Removing Obstacles to Power-Factor Charge, Will Brown. Elec. World, vol. 72, no. 26, Dec. 28, 1918, pp. 1220-1222, 1 fig. Necessity of standard method of measuring power factor and instrument that would be universally applicable: examination into methods now employed in widely separated plants.

Calibration of Power Factor Indicators, Walter Wescott Hoke. Elec. World, vol. 72, no. 23, Dec. 7, 1918, pp. 1076-1078, 4 figs. Method of calibrating polyphase power-factor indicators of which resistances of potential circuits are not equal: also applies to indicators in which current coil is in one phase of a two-phase line.

Rubber-Goods Testing

Safeguarding Electrical Employees. Elec. World, vol. 72, no. 26, Dec. 28, 1918, pp. 1223-1226, 5 figs. How companies which take active interest in well-being of their employees have made use of protective devices to guard against personal injuries: care and testing.

Transmission Factor for Glass

The Measurement of Transmission-Factor, M. Luckiesh and L. L. Mellor. Jl. Franklin Inst., vol. 186, no. 5, Nov. 1918, pp. 529-545, 8 figs. Investigation of various arrangements of apparatus designed to determine transmission factors for several diffusive glasses for illumination (1) by a narrow beam of light directed perpendicularly to surface of specimen, and (2) uniformly diffused light reaching specimen from all directions; examination of effect on value of transmission factor of position of specimen with respect to light and character of side, smooth or rough, upon which light strikes it.

POWER APPLICATIONS

Alloy Production

New Materials Developed in Germany for Electrical Industry (Les nouveaux matériaux dans l'industrie electrique en Allemagne), S. Frid. Industrie Electrique, year 27, no. 624, June 25, 1918, pp. 227-256. Application of alloys such as electron (10 Al + 90 Mn), magnalium, duralumin and other compositions; regulation governing material to be used in various types of electric lines; instruments and apparatus; machines and transformers.

Dairy Farms

Use of Electricity on Dairy Farms to Increase Production. Elec. Rev., vol. 73, no. 26, Dec. 28, 1918, pp. 995-997, 3 figs. Proper lighting and use of electric fans in Georgia farm stables result in greater quantity and better quality of product.

Electrochemical Processes

Electricity Releases Chemistry's Power, James M. Matthews. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 727-750, 46 figs. Some of the uses of electricity in the chemical industry are illustrated with descriptions of uses of electric furnaces and electrically-driven motors and installations of electrolytic works.

Electrolytic and Electrothermic Processes and Products. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 756-766, 12 figs. Brief outline of manufacture of sodium, calcium, magnesium and aluminum; more detailed description of electric-furnace methods of manufacturing calcium carbide, carborundum, silicon, graphite, alundum, fused silica and carbon bisulphide; methods of fixation of atmospheric nitrogen and oxidation of nitrogen; sketches of Birkland-Eyde, Schonherr, and Pauling furnaces.

Gold Dredges

Use of Electricty on Gold Dredges. Elec. Rev., vol. 73, no. 23, Dec. 7, 1918, pp. 881-883, 3 figs. Description of typical dredge; value of central-station service for work; points to observe in selecting apparatus required; description of electrical equipment used.

Harbors

Extensive Use of Electricity for San Francisco Harbor. Elec. Rev., vol. 72, no. 26, Dec. 26, 1918, pp. 1001-1005, 4 figs. Pier, dock and street lighting; electric clock system; harbor lights and fog signals; fire-alarm and telephone system; electric repair and maintenance service; features of wiring.

Shipbuilding

The Application of Electricity in Ships and Shipbuilding, J. F. Nielson. Elecn., vol. 81, no. 2114, Nov. 22, 1918, pp. 621. Abstract of paper before Scottish Local Section of Inst. of Elec. Engrs., Nov. 1918.

Steel Mills

Operating Electrically-Driven Steel Mills, J. T. Sturtevant. Iron Trade Rev., vol. 63, no. 23, Dec. 5, 1918, pp. 1292-1293, 4 figs. Layout, equipment, power consumption, tonnages and capacities of 11 installations at Lehigh plant of Bethlehem Steel Co.

TELEGRAPHY AND TELEPHONY

Antenna

The Vertical Grounded Antenna as a Generalized Bessel's Antenna, A. Press. Proc. Inst. Radio Engrs., vol. 6, no. 6, Dec. 1918, pp. 317-322, 1 fig. General expression for current at any point of antenna formulated by taking account of variable distribution of inductance and capacity; particular solution for current and voltage distribution in case of antenna having zero current at top and maximum current at bottom.

Capacity of a Horizontal Antenna (Capacité d'une antenne horizontale), J-B Pompey. Revue Générale de l'Electricité, vol. 4, no. 21, Nov. 23, 1918, pp. 790-792, 1 fig. Modification of original derivation of Pedersen's formula.

Duplex Polar Transmission

Improving Polar Duplex Transmission. Telegraph & Telephone Age, no. 24, Dec. 16, 1918, pp. 564-565, 5 figs. Diagrams of five different schemes tried in long lines operated polar duplex.

Photographs, Wireless Transmission of

The Design and Construction of Apparatus for the Wireless Transmission of Photographs, Marcus J. Martin. Wireless World, vol. 6, no. 69, Dec. 1918, pp. 509-513, 7 figs. Describes system outlined in handbook on the Wireless Transmission of Photographs as at present developed. Writer's intention is to provide practical groundwork for improvements. (To be continued.)

Radio Telephony

Some Aspects of Radio Telephony in Japan, Eitaro Yokoyama. Wireless World, vol. 6, no. 69, Dec. 1918, pp. 484-487, 5 figs. Influence of gas clearance, dimensions and shape of electrodes upon discharge. From Proc. Inst. Radio Engrs. (Continuation of serial.)

Radio Transmitter

On the Electrical Operation and Mechanical Design of an Impulse Excitation Multi-Spark-Group Radio Transmitter, Bowden Washington. Proc. Inst. Radio Engrs., vol. 6, no. 6, Dec. 1918, pp. 295-315, 31 figs. Discussion of

impulse excitation; description of three forms of gaps suitable for extreme quenching; oscillograms showing operation of such gaps; operation of actual 0.5-kw. and 2-kw. sets.

Spark Discharges

The Revolving Mirror and Spark Discharges, Lindlay Pyle. Wireless World, vol. 6, no. 69, Dec. 1918, pp. 489-490, 1 fig. Shows diagrammatically and describes briefly method of observing and photographing oscillatory nature of "wireless" spark. From Electrical Experimenter.

Spark Gap

A Ventilated Spark Discharge Gap. Wireless Age, vol. 6, no. 3, Dec. 1918, pp. 44-45, 3 figs. Internal construction and action of apparatus said to be silent in operation and to maintain a predetermined operating characteristic.

On the Possibility of Tone Production by Rotary and Stationary Spark Gaps, Hidetsugu Yagi. Proc. Inst. Radio Engrs., vol. 6, no. 6, Dec. 1918, pp. 323-343, 17 figs. Results produced by needle and spherical gaps with a. c. transformer, spark-gap method and with high-tension d. c. spark-gap method; brief treatment of transient conditions existing before establishment of stable tone régime.

Telephone, Sound-Detecting Devices

Telephone Service Standards. Telephony, vol. 76, no. 1, Jan. 4, 1919, pp. 22-23. Investigation of service and transmission standards and experimental work on sound-detecting devices by telephone section of Bureau of Standards, from 1917-1918 report Secretary of Commerce.

Telephone Troubles

How to Locate Telephone Troubles, J. Bernard Hecht. Telephony, vol. 76, no. 1, Jan. 4, 1919, pp. 26-27. Care and maintenance of primary batteries. Instructions to managers, wire chiefs and troublemen of local battery telephone exchanges. Sixth article.

Vacuum-Tube Electrodes

A Method of Constructing Gas-Free Electrodes. Wireless World, vol. 6, no. 69, Dec. 1918, pp. 488-489. Process of manufacturing vacuum tube in which anode consists of coating of metal sprayed on inside of bulb by incandescing refractory metallic conductor, such as tungsten, in partial vacuum. From Wireless Age.

Time Signaling

Wireless Time-Signaling Device, Wireless Age, vol. 6, no. 3, Dec. 1918, pp. 13-14, 3 figs. Apparatus for synchronizing time clocks from one main radio station, permitting at predetermined intervals a correction of errors encountered in clock mechanisms.

TRANSFORMERS, CONVERTERS, FREQUENCY CHANGERS

Radio Frequency Changers

Radio Frequency Changers, E. E. Bucher. Wireless Age, vol. 6, nos. 3 and 4, Dec. 1918 and Jan. 1919, pp. 20-22 and 20-22, 13 figs. Reported progress in their application to wireless telegraphic and telephonic communication. Control of antenna currents.

Rectifiers

Incandescent-Cathode Arc Device for the Rectification of Alternating Currents. Wireless Age, vol. 6, no. 3, Dec. 1918, pp. 14 and 43-44, 3 figs. Construction and electrical connections of tube; arc started by means of a high-voltage discharge from a pointed cathode.

An Enclosed Rectifier. Wireless Age, vol. 6, no. 3, Dec. 1918, pp. 12-13, 3 figs. Incandescent cathode type. Argon at considerable pressure is injected into enclosed medium.

Rotary Converters

The Effect of Power-Factor on Output of Rotary Converters with Reactance Control, R. G. Jakeman. Elecn., vol. 81, no. 2114, Nov. 22, 1918, pp. 614-616, 4 figs. Dealing with effect of power-factor on size of converter.

Transformer Dimensions

Dimensions of Transformers, A. R. Low. Elecn., vol. 81, no. 2113, Nov. 15, 1918, pp. 597-599. Object of article is to classify principal problems of transformer discussion and compare certain assumptions, methods and results.

Transformer Oil

Transformer Oil. W. S. Flight. Elecn., vol. 81, no. 2115, Nov. 29, 1918, pp. 636-638, 4 figs. Author discusses types and characteristics of oils; formation of sludge; minor tests.

Welding, Transformers for

Transformers for Electric Welding, W. S. Moody. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 935-937. Requirements of those used for spot welding and for arc welding; construction found best to fulfill service specifications of each type.

See also ELECTRICAL ENGINEERING, *Transmission, Distribution, Control (Transformer Losses).*

TRANSMISSION, DISTRIBUTION, CONTROL

Central-Station Service

Twenty-Seven Thousand Dollar Saving in Manhattan Building Plant. Power, vol. 48, no. 26, Dec. 24, 1918, pp. 918-919. By using Edison off-peak service during summer months, substituting motor-driven elevator pumps for inefficient steam pumps, installing a feed-water heater and a stoker.

Frequency Control

Better Frequency Control, Henry E. Warren. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 816-819, 3 figs. Method which records revolutions, thus indicating mean frequency and enabling operator to adjust governor-regulating mechanism to maintain average frequency at its normal value practically exact.

Growth of Electric Systems

The Growth of Electric Systems, Julian C. Smith. Can. Engr., vol. 35, no. 25, Dec. 1918, pp. 539-540. Evolution since 1882; direct and alternating transmission systems; why the "hydro" is 25 cycles; thrust bearings and vertical units. From one of the J. E. Aldred lectures on engineering practice, Johns Hopkins University.

Interconnection

Interconnection of Power Systems. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 12, Dec. 1918, pp. 1297-1333, 12 figs. Technical features of interconnection of electric power systems of California; electric power in northern and central California; function of Pacific Gas and Electric Co. in interconnected operation of power companies of central and northern California. Symposium at meeting of San Francisco Section Am. Inst. Elec. Engrs.

Power Factor

Location for Power-Factor Corrective Apparatus, Will Brown. Elec. World, vol. 72, no. 24, Dec. 14, 1918, pp. 1125-1128, 3 figs. Experience with static condensers; dissimilarities in synchronous machines; using idle alternators as condensers; best motor rating for correction; effect of condenser location on result.

Improvement of Power-Factor by the Operation of Synchronous Motors (Note sur l'emploi des moteurs synchrones pour améliorer le facteur de puissance), Paul Rieunier. Revue Générale de l'Electricité, vol. 4, no. 21, Nov. 23, 1918, pp. 771-788, 15 figs. Mathematical and graphic study of equation, $S\ R = \sin \Phi_1 - \cos \Phi_1 \tan \Phi_2$, where S is current supplied in quadrature by synchronous motor, R current absorbed by network with factor power $\cos \Phi_1$ and Φ_1, Φ_2 are the respective phase angles before and after motor is connected. Practical applications are deduced.

St. Lawrence River Transmission Line

111,000-Volt Transmission Line Over the St. Lawrence River, S. Svenningson. Elec. News, vol. 27, no. 23, Dec. 1, 1918, pp. 31-34. Crossing consists of central span 4801 ft. long supported by two 350-ft. towers. Author gives special attention to cables, insulators, ice protection and sag calculations. Paper before Toronto meeting of Am. Inst. Elec. Engrs.

Substations

Effect of a Tie-Line Between Two Substations, H. B. Dwight. Elec. Rev., vol. 73, no. 25, Dec. 21, 1918, pp. 966-968, 1 fig. Methods of calculating effect of tie-lines upon current and voltage; several formulæ given.

The Modern Outdoor Substation, M. M. Samuels. Elec. World, vol. 72, no. 23, Dec. 7, 1918, pp. 1068-1073, 20 figs. Apparatus developed until it is as reliable as indoor equipment; station design not greatly improved; notes on transformers, oil circuit breakers, lightning arresters, air-break switches and bus supports.

A Two-Unit Automatic Substation, Walter C. Slade. Elec. Ry. Jl., vol. 52, no. 24, Dec. 14, 1918, pp. 1038-1044, 13 figs. Description of Rhode Island Co.'s substation at Oakland illustrating latest practice. Economics of automatic substation application.

Synchronous Condensers

Synchronous Condenser in Fuel Conservation, L. N. Robinson. Jl. Elec., vol. 41, no. 10, Nov. 15, 1918, pp. 456-458, 2 figs. Possibilities due to quadrature phase relation of energy and wattless components of current in virtue of which a synchronous condenser can deliver, under given line regulations, wattless current corresponding to 10,000-kv-a, and simultaneously absorb as motor or deliver as generator 10,000 kw. with total current corresponding to only 14,100 kv-a.

Transformer Losses

Influence of Distributing System on Transformer Losses in Large Networks (Pertes dans les transformateurs des grands réseaux suivant le système de distribution employé). Revue Générale de l'Electricité, vol. 4, no. 19, Nov. 9, 1918, pp. 721-724, 5 figs. Study and comparison of losses in two systems: (1) uniform distribution at 20,000 to 30,000 volts and (2) distribution at 30,000 to 50,000 volts in main network with reduction to 6,000 to 20,000 volts in secondary lines. From Electrotechnische Zeitschrift.

See also ELECTRICAL ENGINEERING, *Generating Stations (Steam-Electric Stations).*

VARIA

Battery Charging, A. C.

High-Tension Battery Fed with Alternating Current (Sur une batterie à haute tension alimentée à courant alternatif). Industrie Electrique, year 27, no. 633, Nov. 10, 1918, pp. 416-417, 1 fig. Principle and diagram of apparatus which by an arrangement of Grætz valves and condensers connected to secondary winding of transformer permits conversion of alternating current into direct current at voltages up to 10,000. From Bulletin de l'Association Suisse des Electriciens, Apr. 1918.

Contract Clauses

Power Factor Clauses in Contracts, Will Brown. Elec. World, vol. 72, no. 25, Dec. 21, 1918, pp. 1164-1165. Commercial problems involved; opinions from widely scattered central stations regarding necessity of considerating power factor; typical clauses of two types of contract which base charges on average power factor.

Electrolysis Protection

Drainage if Necessary vs. Negative Feeder Electrolysis Protection, D. W. Roper. Elec. Ry. Jl., vol. 52, no. 23, Dec. 7, 1918, pp. 1003-1007, 12 figs. Comparison of plans used in St. Louis and Chicago for eliminating damage to underground structures from power company viewpoint. (Abstract of paper before Am. Inst. Elec. Engrs., St. Louis.)

Fires in Oil Switches

R. Frère Process of Extinguishing Fires in High-Tension Oil Switches (L'extinction des feux d'huile dans les cellules d'interrupteurs à haute tension par les procédés R. Frère), Ch. Benjamin. Génie Civil, vol. 73, no. 19, Nov. 9, 1918, pp. 361-363, 10 figs. Fundamental principle of process consists in reducing oxygen in atmosphere by a large quantity of inert gas such as nitrogen.

International Electrotechnic Commission

International Electrotechnic Commission (La Comision Electrotécnica Internacional), German Niebuhr. Boletin de la Asociación Argentina de Electro-Técnicos, vol. 4, no. 8, Aug. 1918, pp. 783-788. Its origin, development and work. (To be continued.)

Lightning Arresters

Substitution of Copper for Platinum in Lightning Rods on Account of Present Shortage of Platinum (L'emploi du platine et du cuivre sur les paratonnerres et la crise du platine), E. Lignorelles. Génie Civil, vol. 73, no. 18, Nov. 2, 1918, pp. 351-353. States that aluminum, copper and iron are satisfactory for lightning rods; gives suggestions as to proper installation.

Storing Direct-Current Aluminum Arresters for the Winter, F. T. Forster. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 820-821. Ill effects of leaving plates standing in electrolyte when arrester is out of service; method of preparing arresters for storage.

Civil Engineering

BRIDGES

Arch Bridge

The Rock Island Builds Two Rainbow Arch Bridges. Ry. Age, vol. 65, no. 23, Dec. 6, 1918, pp. 1003-1005, 4 figs. Limited-weight concrete structure with shallow floor.

Erection

Erection Experiences at the Sciotoville Bridge, Clyde B. Pyle. Eng. News-Rec., vol. 81, no. 26, Dec. 26, 1918, pp. 1182-1186, 6 figs. Machines used found efficient; adjustment of bridge easy; deflections agreed with computed values; last of three articles on field work.

Pontoon Bridge

The Sardah (India) Pontoon Bridge. Ry. Engr., vol. 39, no. 467, Dec. 1918, pp. 221-222,

6 figs. Principles of construction, method of use and structural details of 420 ft. 7-pontoon bridge. From report of Technical Section of Railway Branch, Public Works Department, Government of India.

Railway Bridges

General Specification for Steel Railway Bridges. Jl. Eng. Inst. Can., vol. 1, no. 8, Dec. 1918, pp. 367-385, 3 figs. Final draft as approved by meeting of committee of the Institute.

Reinforced Concrete Flat Slab Railway Bridges, A. B. Cohen. Ry. Gaz., vol. 29, no. 20, Nov. 15, 1918, pp. 528-530, 2 figs. Advantages of this type and details of Lackawanna terminal at Buffalo, N. Y. Paper before joint session of Am. Concrete Inst. and Am. Soc. for Testing Materials.

Stress Measurements on Niagara Gorge Railway Bridge, Charles Evans Fowler. Eng. News-Rec., vol. 81, no. 26, Dec. 26, 1918, pp. 1172-1175, 6 figs. Permissible loading studied by strain gage; dead-load condition of arch determined by forcing crown apart and measuring release of stress.

BUILDING AND CONSTRUCTION

Barracks

Temporary Barracks at Rosedale Heights. Contract Rec., vol. 32, no. 52, Dec. 25, 1918, pp. 1019-1022, 6 figs. Disposition and finish of 24 buildings rapidly completed for Toronto demobilization depot.

Gypsum Houses

Houses of Gypsum Have Many Advantages. Contract Rec., vol. 32, no. 51, Dec. 18, 1918, pp. 1006-1007, 1 fig. Mode of constructing walls of gypsum blocks cast from gypsum mortar.

Hospitals

Details of Hospital Construction, N. V. Perry. Modern Hospital, vol. 11, no. 6, Dec. 1918, pp. 469-471, 5 figs. Remarks on general requirements, adaptable equipments for ward lighting, suitable arrangement of heating system, and special features demanded in floor construction. Paper before convention of Am. Hospital Assn.

Mills

The Reconstructed Plant of the Quaker Oats Company at Peterboro, Ont. Contract Rec., vol. 32, no. 47, Nov. 20, 1918, pp. 918-921, 6 figs. Work done in clearing site in plant destroyed by fire; layout of new buildings.

Ornamentation

Structural Ornamentation. Vol. 70, no. 6, Dec. 1918, pp. 506-507. Study in face brick, fancy brick, architectural terra cotta and decorative tile as factors in the clayworking industry.

Roofing

English Slate and Tile Roofing Methods. Metal Worker, vol. 90, no. 26, Dec. 27, 1918, pp. 703-705, 9 figs. Plain and ornamental slating; single- and double-nailing methods; hints on making repairs.

School

Test of Chicago and Cook County School for Boys, Meyer J. Sturm. Heat. & Vent. Mag., vol. 15, no. 12, Dec. 1918, pp. 41-44, 5 figs. Description of building and its equipment.

Slabs and Culverts

Practice in the Design of Concrete Floor Slabs and Flat Top Culverts, Geo. H. Tinker. Bul. Am. Ry. Eng. Assn., vol. 20, no. 210, Oct. 1918, pp. 3-19. Summary of replies from bridge engineers connected with various railroads to questionnaire in regard to their practice concerning longitudinal, transverse and vertical distribution of axle loads and impact allowance in designing culverts and slabs; a short analysis of the salient points also presented.

Timber Framing, Steel in

How to Use Steel in Timber Framing, Ernest Irving Freese. Building Age, vol. 41, no. 1, Jan. 1919, pp. 13-15, 9 figs. Practical methods of supporting long-span floors and bearing partitions upon structural steel girders.

CEMENT AND CONCRETE

Cold-Weather Concrete

Some Temperature Records of Cold Weather Concrete, L. J. Towne. Stone & Webster Jl., vol. 23, no. 6, Dec. 1918, pp. 414-417, 3 figs. Tests made to secure data on amount of protection necessary to prevent concrete from freezing before setting can take place. On account of heat generated as result of chemical actions incident to setting concrete does not follow daily variations in air temperatures.

Compression Tests

Some Compression Tests of Portland Cement Mortars and Concrete Containing Various Percentages of Silt, Arthur C. Alvarez and James R. Shields. Univ. of Cal. Publications in Eng., vol. 2, no. 3, Nov. 19, 1918, pp. 119-130, 1 fig. Concludes that at age of 28 days the compressive strength of 1:2:4 concrete stored in water increases with increase in percentage of silt for amounts up to 14 per cent by weight of sand, and that of mortars varying in proportion between 1:1 and 1:4 is reduced on an average by about 4.5 per cent with 10 per cent silt.

Oil

Oil and Concrete. Ry. Engr., vol. 39, nos. 462 and 466, July and Nov., 1918, pp. 135-137 and 207-210. Results of laboratory tests on different specimens and under varied conditions; L. Waller Page's experiments on waterproofing concrete; W. Lawrence Gadd's conclusions from his investigation of Page's results; accounts of other experimenters. (To be continued.)

Poles

Hollow Concrete Poles Made by New Method. Ry Age, vol. 65, no. 25, Dec. 20, 1918, pp. 1127-1128, 3 figs. Important savings in weight over solid construction are effected by centrifugal process.

Study of the Construction of Latticed Girder Poles for Electrical Lines (Contributo allo studio delle palificazioni per condutture elettriche), Ettore lo Cigno. L'Elettrotecnica, vol. 5, no. 29, Oct. 15, 1918, pp. 402-407, 7 figs. Analytical investigation of stresses in latticed girder poles of square base with formulæ and graphs for examination of relative significance of mechanical coefficients.

Setting Process

The Setting Process in Lime Mortars and Portland Cements, Cecil H. Desch. Contract Rec., vol. 32, no. 47, Nov. 20, 1918, pp. 922-923. Review of researches undertaken and hypotheses advanced.

Waterproofed Floors

Waterproofed Floors for Railway Crossings Over Streets, H. T. Welty. Eng. News-Rec., vol. 81, no. 24, Dec. 12, 1918, pp. 1081-1086, 9 figs. Grade-crossing work makes severe demands; troughing unsatisfactory; concrete slab floor; methods of sealing concrete to girders.

See also CIVIL ENGINEERING, Building Construction (Slabs and Culverts); Earthwork, Rock Excavation, etc. (Dams).

EARTHWORK, ROCK EXCAVATION, ETC.

Dams

Progress on Concrete Dam at Paris, Ont. Contract Rec., vol. 32, no. 49, Dec. 4, 1918, pp. 955-956, 2 figs. Method of bracing framework.

Construction Features of a Multiple Arch Dam, L. R. Jorgensen. Jl. Elec., vol. 41, no. 11, Dec. 1, 1918, pp. 506-508, 3 figs. Considers details of construction methods with reference to an actual case.

A Veritable Niagara Created in the South—Mammoth Hydro-Electric Development in East Tennessee, Stuart Towe. Mfrs. Rec., vol. 75, no. 1, Jan. 2, 1919, pp. 143-145, 3 figs. Brief description of dam 225 ft. high, 725 ft. long at top and 350 ft. at base, 175 ft. thick at base and 12 ft. at top. For a 90,000-hp. hydroelectric development.

New Concrete Dam and Bridge Over Lynn River at Port Dover. Contract Rec., vol. 32, no. 52, Dec. 25, 1918, pp. 1031-1033, 6 figs. Excavation work; specifications for aggregate.

The Lake Eleanor Dam, Rudolph W. Van Norden. Jl. Elec., vol. 41, no. 12, Dec. 15, 1918, pp. 551-553, 4 figs. Plans, essential features and details of construction. Dam contains 11,000 cu. yd. of concrete.

HARBORS

Floating Docks

Construction and Trials of 30,000-Ton Black Sea Floating Dock. Engineering, vol. 106, no. 2759, Nov. 15, 1918, pp. 551-552, 3 figs. Drawings with principal dimensions and description.

San Francisco Harbor

Harbor Improvements at San Francisco, Charles W. Geiger. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 31-35, 7 figs. Extensive enlargement of piers; large bulkhead warehouses; railroad connection with piers; developments in Islais Creek section.

See also ELECTRICAL ENGINEERING, Power Applications (Harbors).

MATERIALS OF CONSTRUCTION

Road Materials

Standard Forms for Tests, Reports, and Method of Sampling for Road Materials. Better Roads & Streets, vol. 8, no. 8, Aug. 1918, pp. 300-306, 2 figs. From Bul. 555 issued by office of Public Roads and Rural Eng.

Stucco

Review of Stucco Tests by Bureau of Standards, J. C. Pearson. Cement & Eng. News, vol. 30, no. 12, Dec. 1918, pp. 36-37. From paper at annual meeting of Am. Concrete Inst.

MECHANICS

Arches

Calculation of Built-In Arches Under the Action of Continuous External Loads (Calcul des arcs encastrés sollicités par des charges extérieures continues), P. Ernest Flamard. Génie Civil, vol. 73, no. 11, Sept. 14, 1918, pp. 207-209, 4 figs. Mathematical study of problem with reference to work of deformation.

Beams

Beam Deflections Under Distributed or Concentrated Loading, J. B. Kommers. Eng. News-Rec., vol. 82, no. 1, Jan. 2, 1919, pp. 44-46, 10 figs. New algebraic method proposed for cases usually solved by graphical calculation gives accurate results.

Bending Moments in Grillage Beams, R. Fleming. Eng. & Contracting, vol. 50, no. 26, Dec. 25, 1918, pp. 585-586, 1 fig. Outcome of recent review of calculations for proportioning grillage beams in foundations.

Lines of Influence for a Vierendeel Beam (Lignes d'influence pour une poutre Vierendeel), G. Magnel. Génie Civil, vol. 73, no. 18, Nov. 2, 1918, pp. 344-347, 5 figs. Mathematical investigation of bending moments and other mechanical factors in reinforced concrete beam.

ROADS AND PAVEMENTS

Boulevards

Boulevards of San Francisco, California, Charles W. Geiger. Good Roads, vol. 17, no. 1, Jan. 4, 1919, pp. 1-3, 5 figs. Notes on history and construction of scenic drives in and near city.

Concrete Pavements

Concrete Pavement Subjected to Severe Test, George C. Swan. Concrete Highway Mag., vol. 2, no. 11, Nov. 1918, pp. 246-247, 3 figs. Damage at crossing where locomotive was thrown off track and dragged itself 40 ft. over concrete surface.

Construction

Construction Methods Employed in Building Lincoln Highway Cut-Off Across the Desert at Gold Hill, Utah, R. E. Dillree. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 195-197, 12 figs. Building roadway with grade above level of desert under conditions which necessitated using hay to keep heavy equipment from bogging down.

Disintegration of Roads

The Road: Its Paramount Importance as Viewed by a Briton, J. H. A. MacDonald. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 218-221. Concludes necessity of building good roads from analysis of London traffic statistics and considers problem of road disintegration and that of paying for roads.

Hard-Surface Pavements

The Prevention of Longitudinal Cracks in Hard Surfaced Pavements, Wm. C. Perkins. Contract Rec., vol. 32, no. 49, Dec. 4, 1918, pp. 972-973. Suggests use of tile in artificial foundation.

Macadam Roads

The Maintenance of Macadam Roadways, R. C. Heath. Contract Rec., vol. 32, no. 52, Dec. 25, 1918, pp. 1033-1034. Preventing wear and raveling; carpet treatment; economic importance of road maintenance. Paper before Ky. Highway Engrs. Assn.

Snow Removal

Organization, Methods and Equipment Employed in Removing Snow from Main Roads in Pennsylvania, George H. Biles. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 216-218. Address before Highway Traffic Assn. of N. Y. State.

Snow Removal on Trunk Line Highways, Charles J. Bennett. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 214-215, 3 figs. Address before Highway Traffic Assn. of N. Y. State.

State Highways

State Highway Work in 1919. Good Roads, vol. 17, no. 1, Jan. 4, 1919, pp. 4-6. Report of available funds and plans for work in 31 states.

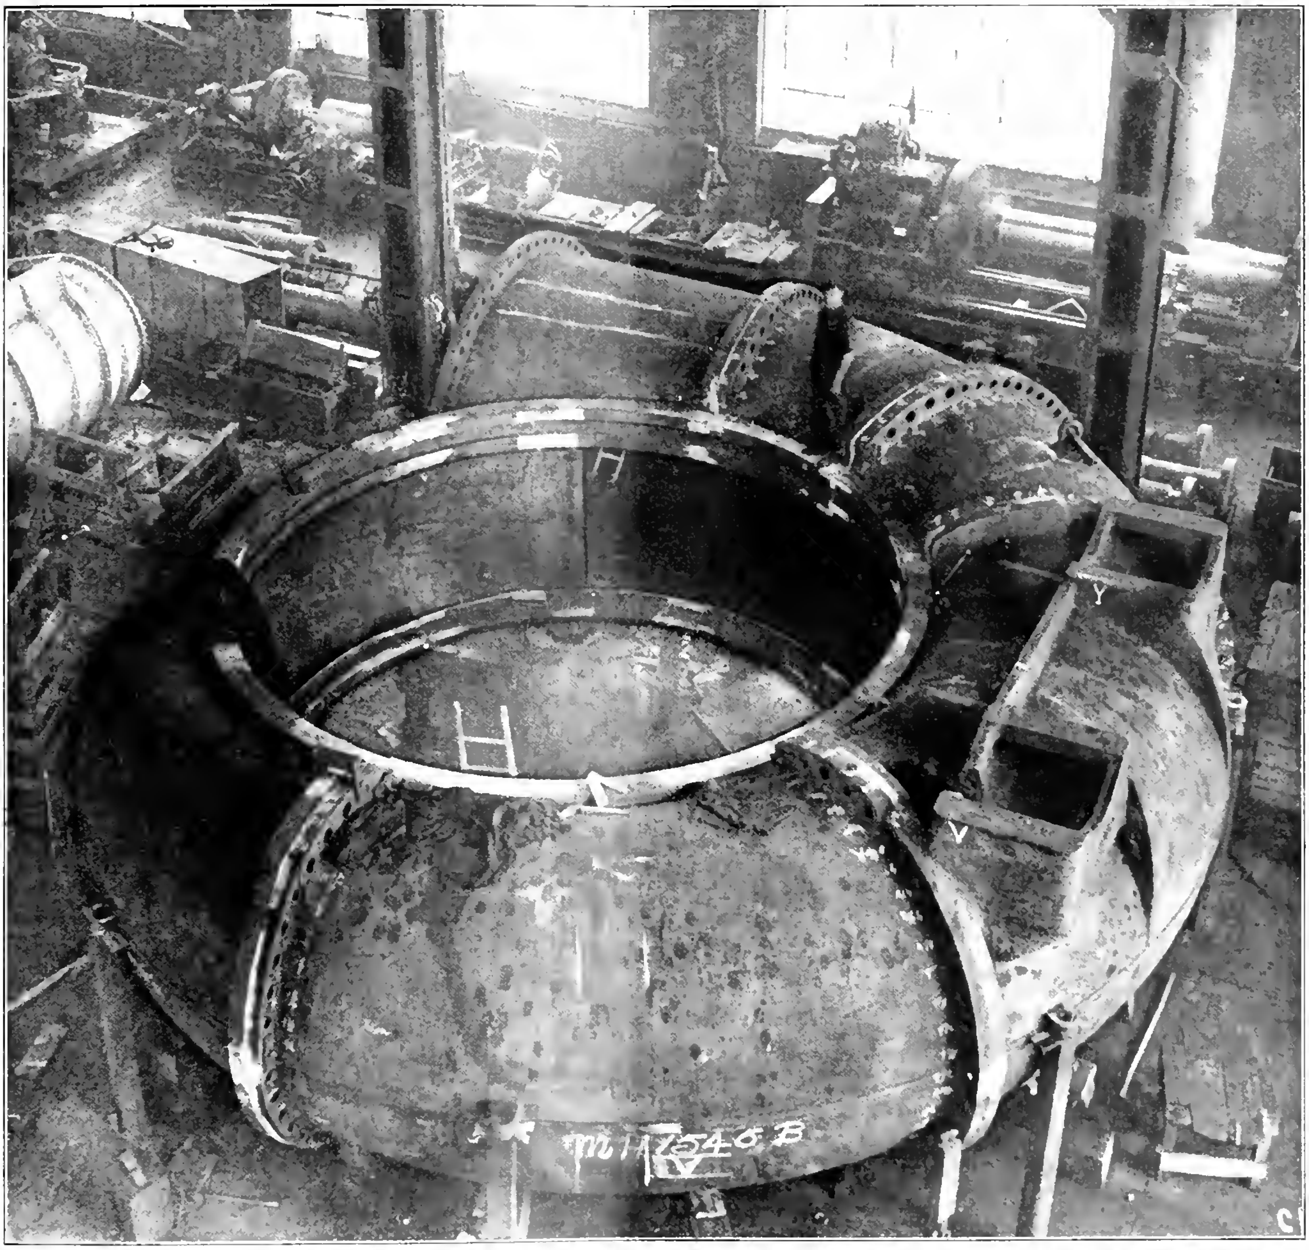
War, Roads During

Construction and Maintenance of Roads During War. Better Roads & Streets, vol. 8, no.

I. P. Morris Hydraulic Turbines

The Wm. Cramp & Sons Ship & Engine Building Co.

Richmond and Norris Sts., Philadelphia



THE MOST POWERFUL TURBINE EVER BUILT

Cast iron volute casing of **37,500 H. P.** Turbine for The Niagara Falls Power Company The turbine is designed to develop the above power under a head of 214 feet, at a speed of 150 R. P. M. We have two of these units now under construction in our shops.

S. Aug. 1918, pp. 299 and 324. Policy issued by Council of Nat. Defence.

See also CIVIL ENGINEERING, *Materials of Construction (Road Materials).*

SANITARY ENGINEERING

Sewage Disposal

Sewage Disposal from an Operator's Standpoint, William K. F. Durrant. Can. Engr., vol. 35, no. 24, Dec. 12, 1918, pp. 512-513. Comments on each of features of plant consisting of detritus pit and screen chamber, pump house, plain sedimentation tanks, bacteria beds, disinfecting chambers and humuspond. Abstracted from Western Min. News.

The Private Sewerage Question, D. H. Wyatt. Clay-Worker, vol. 70, no. 6, Dec. 1918, pp. 500-501. Analysis of results produced by leaky building drains and sewers. Vitrified pipe advocated as well constituted to withstand chemical action.

The Aqua Privy. Indian Eng., vol. 64, no. 14, Oct. 5, 1918, pp. 192-193, 3 figs. Special feature is that nightsoil goes straight into small septic tank under seat, where it undergoes septic treatment.

Concrete Septic Tanks and Subsoil Disposal Fields for Country Homes, John H. Perry. Domestic Eng., vol. 85, no. 10, Dec. 7, 1918, pp. 363-365 and 391, 5 figs. Design and construction of such systems.

Sanitary Conveniences and Comforts for Country Homes. Clay-Worker, vol. 70, no. 6, Dec. 1918, pp. 501-503, 3 figs. Illustrates a manner in which ordinary sewer pipe and drain tile may be used.

Sewage-Pumping Station

Design and Operation of Automatic Sewage Pumping Station at West Haven, Conn., Clyde Potts. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 199-200, 2 figs. Draining sewage to common point for treatment.

WATER SUPPLY

Freezing

How to Prevent Freezing of Riser Pipes to Elevated Water Supply Tanks. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 213-214. Four means: (1) providing method for artificially heating water; (2) conserving heat in water by providing sufficient insulation; (3) maintaining temperature of water above freezing point by pumping and withdrawal of water; (4) adding chemicals to lower freezing point. From Water Tower.

Purification

Four Years' Operating Results of Minneapolis Water Purification Plant. Contract Rec., vol. 32, no. 47, Nov. 20, 1918, pp. 926-927. Filtration data of plant having capacity of 96,000,000 gal.

Algal Growths and Chlorine Treatment of London Waters, A. C. Houston. Contract Rec., vol. 32, no. 47, Nov. 20, 1918, pp. 929-930. Report of Director of Water Examination.

Water Treatment at Council Grove, Kansas, Louis L. Tribus. Can. Engr., vol. 35, no. 25, Dec. 19, 1918, pp. 536-538, 4 figs. Results obtained under highly varying conditions of turbidity at plant in operation for three years. Paper before Am. Waterworks Assn.

Reservoir Capacity

Determination of the Available Water Supply in the Haut-Cher Basin (Contribution à la détermination du régime hydraulique du Cher), P. Morin. Revue Générale de l'Electricité, vol. 4, no. 21, Nov. 23, 1918, pp. 805-806, 1 fig. Account of observations made to determine capacity of reservoirs which would insure continuous delivery.

Stream Pollution

Control of Stream Pollution, Earle B. Phelps. Can. Engr., vol. 35, no. 24, Dec. 12, 1918, pp. 515-518. Considers use of streams for waste disposal, effect of stream pollution, self-purification of streams, chemical methods of sewage treatment, biological treatment of sewage, and purification of water. From J. E. Aldred Lecture on Eng. Practice.

Relation of Main Drainage to River and Harbor Front Improvements in Various American Cities, Morris Knowles and John M. Rice. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 204-205. Special reference to methods adopted for eliminating nuisance caused by discharge of raw sewage at Baltimore, New Bedford, Mass., Cleveland, Toronto, Syracuse, N. Y., Washington, Cincinnati, Waterbury, Conn., and Harrisburg, Pa.

WATERWAYS

Canal Traffic

The Potentialities of Our Inland Water Routes, Robert G. Skerrett. Rudder, vol. 34, no. 12, Dec. 1918, pp. 565-570, 11 figs. Economic and commercial aspects of developing possible canal traffic.

Flumes

Lindsay-Strathmore Irrigation Flume, Stephen E. Kieffer. Can. Engr., vol. 35, no. 25, Dec. 19, 1918, pp. 525-527, 5 figs. Self-supporting, high-level flume with 2-in. walls built on inside forms at rate of 130 lin. ft. per 8-hr. day, nearly $1,500,000 expended in improvements to 15,500 acres in Cal.

Groynes

Groynes as Applied to Water Control and Silt Exclusion. Indian Eng., vol. 64, nos. 14, 15 and 16, Oct. 5, 12 and 19, 1918, pp. 194-195, 206-208 and 222-223, 16 figs. Experiments with silt bags from the results of which writer concludes that when a canal is added to a Bell Bund system, flow behind groyne is introduced, but head still exists in pockets so that arrangement retains power of checking and diverting silt.

Navigable Rivers

The Study of Currents in Navigable Rivers (L'étude des courants dans les revières navigables), P. Dupont. Génie Civil, vol. 73, no. 17, Oct. 26, 1918, pp. 327-329. Recommends study of currents by engineers in order not to differ so often with mariners in regard to construction of improvements.

Calculations in Regard to Improvement of Rivers (Calculs concernant les améliorations de rivières), Alf. Bijls. Génie Civil, vol. 73, no. 19, Nov. 19, 1918, pp. 371-373, 1 fig. Concludes from examination and comparison of formulæ generally used, that in calculations it is advisable to deduce the coefficient of velocity from observations on long sections of 10 to 20 km. and to gage water at all possible levels.

Sediment in Rivers

Sediment in River Waters, J. S. Ryan. Tran. Inst. Marine Engrs., vol. 30, no. 238, Oct. 1918, pp. 217-218, 2 figs. Experience with propeller and shaft due to working amid water mingled with sand.

St. John River

St. John River Affords Big Opportunities, Frank S. Small. Can. Engr., vol. 35, no. 23, Dec. 5, 1918, pp. 489-495, 3 figs. Topographical features; reclamation of waste land by drainage; utilization of water powers; site proposed for tideless harbor.

St. Lawrence River

Canada's Heritage in the St. Lawrence River, Arthur V. White. Can. Engr., vol. 35, no. 24, Dec. 12, 1918, pp. 507-510, 2 figs. Indicates power sites on river and refers to canalization of river as a unit. Address before Elec. Club of Toronto.

Canada's Heritage in the St. Lawrence River, Arthur V. White. Elec. World, vol. 72, no. 26, Dec. 28, 1918, pp. 1216-1217, 1 fig. Estimated low-water power aggregates 2,000,000 hp., of which greater part is wholly within territorial area of Dominion and capable of development. From address before Elec. Club of Toronto, Nov. 12, 1918.

Mining Engineering

COAL AND COKE

California

Tesla Coal Mine, J. W. Beckman. Jl. Elec., vol. 41, no. 12, Dec. 15, 1918, p. 559. Indicates possibilities of a lignite mine in California.

Colliery Output

South Staffordshire and Warwickshire Institute of Mining Engineers. Presidential address, William Charlton. Trans. Instn. Min. Engrs., vol. 56, part 1, Nov. 1918, pp. 13-26. Considers question of output in collieries under two aspects: 1, immediate and pressing need for United Kingdom to produce utmost possible quantity of coal; 2, standpoint of output per unit of person employed, and its bearing on prosperity of coal industry, and those other industries whose ultimate economic position is affected by use and cost of fuel.

What One Coal Mine Has Done. Stone & Webster Jl., vol. 23, no. 5, Nov. 1918, pp. 354-356. Mine in question hoisted 32,514 tons in one week.

GEOLOGY

Lake Michigan District

Explanation of the Abandoned Beaches About the South End of Lake Michigan, G. Frederick Wright. Bul. Geol. Soc. Assn., vol. 29, no. 2, June 1918, pp. 235-244, 3 figs. Peat deposits; series of moraines; supposed changes of level; glacial and clay deposits underneath Chicago; provisional estimates of glacial time afforded in this area. Presented in abstract before the Soc.

MAJOR INDUSTRIAL MATERIALS

Tungsten

Chief Materials Needed in the Electrical Industry: Tungsten (De quelques matières premières nécessaires à l'industrie électrique: le tungstène), D. Pector. Revue Générale de l'Electricité, vol. 4, no. 4, July 27, 1918, pp. 121-125. Metallurgy, uses and ore deposits. Bibliography of documents.

Zinc Concentration

Concentration of Lead-Zinc-Silver Ore at the Zinc Corporation's Mine, George C. Klug. Min. Mag., vol. 19, no. 5, Nov. 1918, pp. 243-245, 1 fig. Methods employed at Broken Hill. Gravity concentration by jigging and tabling for production of high-grade lead concentrate; treatment of zincy tailing by flotation methods (De Bavay, and Delprat); Seale-Shellshear method of cascading as modified by Lyster and Hebbard for selectively separating galena from mill pulp.

Zinc Tailings

Treatment of Accumulated Tailing as Practised by the Zinc Corporation, George C. Klug. Min. Mag., vol. 19, no. 6, Dec. 1918, pp. 298-300, 1 fig. Plant recovering zinc, silver and lead by mineral-separation process of removal in collective float and subsequent separation of a lead concentrate from collective float by tabling methods.

MINES AND MINING

Field Tests

Field Tests for the Common Metals in Minerals, George R. Fansett. Univ. of Ariz. Bul., bul. 93, Min. Technology Series no. 21, Nov. 1918, 20 pp. Compiled for Ariz. State Bur. of Mines and intended as text for lectures on Prospector's Mineralogy.

Fire Protection

Smothering Mine Fires (Note sur l'embouage des feux de mine), M. Cabane. Bulletin et compter rendus mensulels de la Société de l'Industrie Minérale, series 5, vol. 14, 3d issue 1918, pp. 67-77, 6 figs. Principal features of system developed at Commentry Collieries; arrangement at Decazeville mines designed to deliver dust under pressure; materials used to form dust.

Safety

Miners' Safety and Health Almanac for 1919, R. C. Williams. Department of Interior, Bur. of Mines, Miners' Circular 24; 48 pp., 7 figs. Responsibility of miners concerning their own safety and that of others; pure drinking water for mining camps; prevention of accidents and promotion of sanitation; miners' anemia; disposal of human excreta in rural districts; sewage disposal in mines; mine-rescue cars of Bureau of Mines. Other articles dealing with health conditions and tending to impart information to miners are included in bulletin.

Sampling.

Sampling, F. W. Bunyan. Min. & Sci. Press, vol. 117, no. 25, Dec. 21, 1918, pp. 827-832, 2 figs. Emphasizes importance of sampling in analytical work and illustrates with examples value of systematic procedure in performing it.

Stoping Methods

Mining Methods of United Verde Extension Mining Co., Charles A. Mitke. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 9-22, 3 figs. Considerations which influenced selection and planning of adaptable stoping method. Ore deposit considered as replacement of volcanic schist. Mineralization believed to have taken place after intrusions of diorite and quartz porphyry had folded and faulted schist.

Ventilation

Cooling and Drying the Air in Deep Mines, Sydney F. Walker. Iron & Coal Trades Rev., vol. 47, no. 2645, Nov. 8, 1918, p. 518. Writer believes coal may be mined successfully at depths from 5000 to 6000 ft. by treating each individual mine, each pair of shafts and the workings connecting them, in same manner as modern cold stores are treated. Gives recommendations and refers to actual installations.

Welfare Work

Welfare Work in the Mining Work in the Mining Industry, H. Lipson Hancock. Chem. Eng. & Min. Rev., vol. 10, no. 121, Oct. 5, 1918, pp. 6-13, 18 figs. Betterment work being done by South Australian company.

MINOR INDUSTRIAL MATERIALS

Arsenic

Arsenic and Its Occurrences in South Queensland (1), H. I. Jensen. Queensland Government Min. Jl., vol. 19, no. 221, Oct. 15, 1918, pp. 455-458. Notes on arsenic as a

source of trouble in metal extraction and on its origin and extraction.

OIL AND GAS

Gas Pressure

Record of Gas-Pressure from a Borehole, Charles J. Fairbrother. Trans. Instn. Min. Engrs., vol. 56, part 1, Nov. 1918, pp. 6-8, 2 figs. and (discussion) pp. 8-10. Photographs showing gas blowing out of borehole while clear of rods, and borehole with rods in and water being blown in all directions by force of gas.

Gas Storage

Natural-Gas Storage, L. S. Panyity. Bul. Am. Min. Engrs., no. 145, Jan. 1919, pp. 25-25, 2 figs. Scheme to regulate pressure by connecting exhausted well to high-pressure gas line.

Petroleum Hydrology

Petroleum Hydrology Applied to Mid-Continent Field, Roy O. Neal. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 1-8. Method of distinguishing between waters that encroach upon oil-bearing beds from sources in stratum and waters that reach oil sands from planes above.

PRECIOUS MINERALS

Gold

Two Instances of Mobility of Gold in Solid State, Edward Keller. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 33-42, 1 fig. Assay results of gold movement on surface of auriferous copper when latter is subjected to oxidation.

RARE MINERALS

New Minerals

Review of New Mineral Species (Revue des espèces minérales nouvelles), P. Gaubert. Bulletin de la Société Française de Minéralogie, vol. 41, no. 4-5-6, Apr.-June 1918, pp. 93-96 and 117-130. General notes on appearance, occurrence and constitution of 29 minerals discovered in recent years. Reference made in each case to publication where first account of substance appeared.

See also INDUSTRIAL TECHNOLOGY, Yttrium.

Metallurgy

BLAST FURNACES

Development in 1918

1918 Blast Furnace Development Reviewed, F. H. Wilcox. Blast Furnace, vol. 7, no. 1, Jan. 1919, pp. 30-31. Analysis indicates tendency has been toward large hearths, steep and low boshes, high inwall batters and moderate thickness of lining.

Gases

Remarks on the Composition of Blast-Furnace Gases and Volumetric Methods of Measuring the Gas Produced and the Air Blown In (Remarques relatives à la composition des gaz de haut fourneau et méthodes volumetriques pour le calcul du gaz produit et du vent soufflé), J. Seigle. Bulletin et Comptes rendus mensuels de la Société de l'Industrie Minérale, series 5, vol. 14, 3d issue 1918, pp. 113-131, 1 fig. Methods of measuring gases by weight (Gruner and Ledebur); volumetric methods based on combination of carbon or on combination of oxygen; examples of applications; comparison of theoretical results and practical analyses.

Manganese

How to Save Manganese and Coke. Iron Trade Rev., vol. 63, no. 24, Dec. 12, 1918, pp. 1347-1348. Table of operating data of 12 blast furnaces producing ferromanganese and spiegeleisen and 40 per cent of output of manganese alloys in U. S. Conclusion reached that large savings can be effected by using low-ash cokes.

Research

Study of Blast Furnaces, Based on the Researches Undertaken by Francis Mulet (Etude sur les hauts fourneux dapres les travaux de Francis Mulet), E. Damour. Bulletin et Comptes rendus mensuels de la Société de l'Industrie Minérale, series 5, vol. 14, 3d issue 1918, pp. 5-47, 1 fig. Economical operation of furnaces; analysis of charge and of gaseous products; heat required by chemical reactions; influence of temperature of blast on coke economy; utilization of gases; variation in coke consumption with output.

See also MECHANICAL ENGINEERING, Fuels and Firing (Blast Furnace Gas).

COPPER

Brass, Cartridge

A Comparison of Grain-Size Measurements and Brinell Hardness of Cartridge Brass, W. H. Bassett and C. H. Davis. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 57-78, 16 figs. It was found that grain sizes of brasses annealed at low temperatures are greatly affected by previous grain size and reduction by rolling, consequently hardness of cartridge brass may be better determined by Brinell-hardness measurement than from grain size.

Bronzes

The Constitution of the Tin Bronzes, Samuel L. Hoyt. Bul. Am. Inst. Min. Engrs., no. 144, Dec. 1918, pp. 1721-1727, 15 figs. Explains upper heat effect over $\alpha + \beta$ range.

Chloridizing Roasting

Chloridizing-Roasting of Burnt Pyrites on the Ramen-Beskow System, Peter Klason. Min. Mag., vol. 19, no. 6, Dec. 1918, pp. 301-313, 4 figs. Suggests improvement of Longmaid-Henderson process for extracting copper from pyrites that have been burnt by alkali manufacturers.

Copper-Aluminum Alloys

Constitution and Hardness of Copper-Aluminum Alloys Having High Percentage of Copper (Constitution et dureté des alliages cuivre-aluminium riches en cuivre). La Metallurgie, year 50, no. 45, Nov. 6, 1918, pp. 1631-1633, 1 fig. Effect of temperature of hardening on hardness of alloys containing 9 to 16 per cent aluminum. (Continuation of serial.)

Leaching

The Utah Copper Enterprise (VIII). The Leaching Plant, T. A. Rickard. Min. & Sci. Press, vol. 117, no. 24, Dec. 14, 1918, pp. 787-791, 5 figs. Oxidized cap stripped from main mass of sulphide ore, averaging 0.65 per cent Cu in form of carbonates and 0.1 to 0.2 per cent additional in form of chalcopyrite and chalcolite, is dissolved with H_2SO_4 derived from decomposition of sulphide mineral. Plant has capacity of 2000 tons of ore per day. (To be continued.)

FLOTATION

Ruth Flotation Machine

Ruth Flotation Machine, Arthur J. Hoskin. Queensland Government Min. Jl., vol. 19, no. 222, Nov. 15, 1918, pp. 500-501, 3 figs. Machine for concentrating minerals by oil flotation; designed on principle that best attachment of minerals to bubbles takes place when there is least amount of relative motion.

STEEL AND IRON

Basic Steel

Formula for Strength of Basic Steel, Andrew McWilliam. Iron Age, vol. 102, no. 25, Dec. 19, 1918, pp. 1508-1511, 3 figs. Calculations made from composition; influencing principal elements; application to basic steel. Paper before Iron & Steel Inst., London, Sept. 1918.

Cast Iron

The Mixing and Melting of Cast Iron, J. F. Mullan. Can. Foundryman, vol. 9, no. 12, Dec. 1918, p. 304. Review of opinions expressed by several experts leads writer to assert that success of foundry depends more on proper management of furnace than on any other branch of the trade.

Electric Steel

Making Electric Steel for Roller Bearings, Edward K. Hammond. Machy., vol. 25, no. 4, Dec. 1918, pp. 318-326, 20 figs. Methods of operating Héroult electric furnaces, forging ingots, rolling billets and cold-drawing steel into solid bars and seamless tubing.

Ferro-Alloys

The Ferro-Alloys, J. W. Richards. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 751-755. Composition of these alloys, method of manufacture, and properties imparted to steel by addition of each of the molten metals. Also Metal Trades, vol. 9, no. 12, Dec. 1918, pp. 488-489, 2 figs. Properties of ferromolybdenum, ferro-vanadium, ferrotitanium and ferroboron. Paper read at Nat. Exposition of Chem. Indus.

The Manufacture of Ferro-Alloys, Robert M. Keeney. Automotive Eng., vol. 3, no. 10, Dec. 1918, pp. 461-468. Ores and furnaces used and methods followed to produce ferrochrome, ferromanganese, ferromolybdenum, ferrotungsten, ferrovanadium and ferrouranium; uses of these metals.

The Manufacture of Ferro-Alloys in the Electric Furnace, E. S. Bardell. Min. Jl., vol. 123, no. 4316, Dec. 7, 1918, p. 708. Comparative efficiency of large and small furnaces used in manufacture of ferromanganese. Discussion of Am. Inst. Min. Engrs. paper by Robert M. Keeney.

Record of an Old Ferro-Silicon Furnace, I. Peterman. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 492-493. Historical account of plant built in 1792, now a part of Warner Iron Co.

Forged Steel

Influence of Forging and Rolling on the Properties of Steel (Le corroyage de l'acier. Son influence sur les propriétés du metal), Georges Charpy. Revue de Métallurgie, year 15, no. 5, Sept.-Oct. 1918, pp. 427-448, 9 figs. Experiments conducted by engineering staff of large works; records of deformations by forging of straight lines drawn originally on surface of bar and examination of section of hollow threaded cylinder filled with liquid metal of same composition and rolled after solidifying under pressure of 1200 tons from 530 mm. in diameter to 265 mm.

Metallurgy in 1918

Phases of Iron and Steel Metallurgy in 1918, John Howe Hall. Iron Age, vol. 103, no. 1, Jan. 2, 1919, pp. 27-28. Remedies for ingot defects; strides in steel-casting industry; manganese problem; alloy-steel helmets.

Open-Hearth Furnaces

Principles of Open-Hearth Furnace Design, Chas. H. F. Bagley. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 505-507, 3 figs. Calculations relating to pressure in furnace, port ends, ratio of air to gas passages. Flue and valve diagrams. Paper before British Iron & Steel Inst. (Concluded.)

Plate and Structural Mills at Fairfield, Ala. Iron Age, vol. 103, no. 1, Jan. 2, 1919, pp. 47-49, 3 figs. New plant of Tennessee Coal, Iron & Railroad Co., to serve Mobile shipyard; producing steel by triplexing at Ensley open-hearth works.

Oxygen in Steel

Determination of Oxygen in Steel. Iron Age, vol. 102, no. 26, Dec. 26, 1918, pp. 1573, 2 figs. Objections to Ledebur method apparently overcome; details of modifications; interesting comparative analyses.

The Heterogeneity of Steel (L'hétérogénéité de l'acier), H. le Chatelier and B. Bogitch. Génie Civil, vol. 73, no. 18, Nov. 2, 1918, pp. 350-351, 6 figs. Concludes, from experiments with Stead's reagent, that microscopic heterogeneity of steel is due to oxygen in solid solution in metal.

Russian Iron Works

Pre-War Russian Iron and Steel Plants. Iron Age, vol. 102, no. 25, Dec. 19, 1918, pp. 1501-1507, 11 figs. Output and equipment of leading works; prospects after war.

Structure of Steel

Inspecting the Structure of Metals, J. J. McIntyre. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 443-444, 2 figs. Shows manner of taking structural photographs of metals or similar opaque objects with ordinary camera.

Development of Grain Boundaries in Heat-Treated Alloy Steels, R. S. Archer. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 51-55, 12 figs. Specimen is etched in 4 per cent solution of picric acid in ethyl alcohol from 5 to 25 min., then carbonaceous smudge is rubbed off on moist broadcloth or kersey.

See also MECHANICAL ENGINEERING, Heat Treating (Malleable Iron); Machinery, Metal-Working (Steel, High-Speed); ELECTRICAL ENGINEERING, Furnaces (Steel Furnaces).

Aeronautics

AEROSTATICS

Ascending and Landing

Military Aerostatics, H. K. Black. Aerial Age, vol. 8, no. 16, Dec. 30, 1918, p. 811. Precaution in ascending and in landing. (Continuation of serial.)

Balloons

Manufacture of War Balloons in U. S., Allen Sinsheimer. Automotive Indus., vol. 39, no. 22, Nov. 28, 1918, pp. 925-927, 6 figs. Adaptation of French Caquot type.

Free Ballooning

Military Aerostatics, H. K. Black. Aerial Age, vol. 8, no. 14, Dec. 16, 1918, p. 705, 1 fig. Training in free ballooning. (Continuation of serial.)

Kites

Meteorological Kites (Cerfs-volants météorologiques), L.-P. Frantzen. Aérophile, year 26, nos. 19 and 20, Oct. 1-15, 1918, pp. 298-299, 3 figs. Particulars of German design of "Diamant" type.

AIRCRAFT PRODUCTION

Navy Plant

Our Navy Winged Destroyers. Austin C. Lescarboura. Sci. Am., vol. 119, no. 24, Dec. 14, 1918, pp. 480-481 and 486-487, 8 figs. Work done by Navy in establishing Government-owned aircraft plant for supplying giant seaplanes.

Rigging

From a Rigger's Note-Book. Flight, vol. 10, no. 47, Nov. 21, 1918, pp. 1313-1315, 8 figs. General procedure of rigging. Case of a B. E. 2c is taken up in detail.

U. S. Air Service

Report of the Director of Military Aeronautics. Aerial Age, vol. 8, no. 14, Dec. 16, 1918, pp. 720-722. Story of development of personnel, training and organizing phases of present Air Service.

APPLICATIONS

Aeroplane Business

The Future of the Airplane Business. C. F. Kettering. Jl. Soc. Automotive Engrs., vol. 3, no. 6, Dec. 1918, pp. 358-362 and pp. 362-363 (discussion). 2 figs. Present difficulties in civilian use of airplanes as built at present; types of military airplanes. Presidential address before Detroit Section of Society.

American View

Future of the Aircraft Industry. Harry Bowers Mingle. Aviation, vol. 5, no. 9, Dec. 1, 1918, pp. 560-562, 3 figs. Enumerates possible uses of airplane in scientific, civil and sporting fields.

British Civil Transport

Civil Aerial Transport. Flight, vol. 10, no. 48, Nov. 28, 1918, pp. 1350-1351. Outline of report of Civil Aerial Transport Committee regarding steps to be taken to develop aviation for civil and commercial purposes and utilizing trained personnel for that purpose. From London Times.

Control of Aircraft

The Two Futures for Flight. H. Massac Buist. Flight, vol. 10, nos. 48 and 49, Nov. 28 and Dec. 5, 1918, pp. 1352-1354 and 1370-1373. Argues against establishment of bureaucracy in connection with development of aviation alike for military, public and private purposes, and for absolutely free scope for development and application by individuals or companies.

Dutch View of Future

Flying Machines and Air Communication and Navigation in the Near Future (Vliegmachines, bestuurbare luchtschepen en het luchtverkeer in de naaste toekomst). Ph. Kapteyn. De Ingenieur, year 33, no. 43, Oct. 26, 1918, pp. 827-845, 41 figs.

Italian View of Commercial Aviation

Commercial Aviation. Gianni Caproni. Aeronautics, vol 15, no. 264, Nov. 6, 1918, pp. 428-430, 3 figs. From Rivista dei Transporti Aerei.

AUXILIARY SERVICE

Trucks

Building Trucks for the Aviation Service. M. E. Hoag. Am. Mach., vol. 49, no. 23, Dec. 12, 1918, pp. 1089-1092, 13 figs. Description of construction and assembly of some special parts. (Second article.)

ENGINES

Austro-Daimler

The 200 H. P. Austro-Daimler Aero Engine. Flight, vol. 10, no. 46, Nov. 14, 1918, pp. 1288-1293, 7 figs. Ignition; carburetor and induction system; petrol tanks; air pump; water pump; water cooling system; calibration and endurance test report; metallurgical test report; general data; general analysis by weights. Issued by Technical Department, Aircraft Production, Ministry of Munitions. Also Automobile Engr., vol. 8, nos. 120 and 121, Nov. and Dec., 1918, pp. 316-319, 350-357, 28 figs.

Design

The Design of Airplane Engines, III. John Wallace. Automotive Engr., vol. 3, no. 10, Dec. 1918, pp. 458-460. Mean effective pressure; power; construction of a theoretical diagram; modifying diagram to include practical conditions of ignition; comparison of results. (Continuation of serial.)

Hispano-Suiza

The Hispano-Suiza Aircraft Engine. Donald McLeod Lay. Jl. Soc. Automotive Engrs., vol. 3, no. 6, Dec. 1918, pp. 367-372, 9 figs. Historical review of design and development; mechanical features; circulating water and gasoline systems; production problems.

Four Hispano-Suiza Models. Automotive Indus., vol. 39, no. 22, Nov. 28, 1918, pp. 914-915 and 946, 2 figs. Details of models A, I, E, and H, built in U. S.

The Hispano-Suiza Airplane Engine. Aviation, vol. 5, no. 9, Dec. 1, 1918, pp. 549-553, 4 figs. History of development and detailed description of latest type.

Liberty

Details of the Liberty Engine. J. Edward Schipper. Automotive Indus., vol. 38, no. 24, Dec. 12, 1918, pp. 991-995, 12 figs. Mechanical description illustrated with sectional drawings.

Electrical System of the Liberty Engine. J. Edward Schipper. Automotive Indus., vol. 39, no. 26, Dec. 26, 1918, pp. 1089-1092, 14 figs. Special type of interrupter comprising three breakers in parallel. Storage battery designed to permit of upside-down flying.

The Liberty Motor. Douglas Wardrop. Aerial Age, vol. 8, nos. 14 and 15, Dec. 16 and 23, 1918, pp. 706-717, 762-765, 39 figs. Dec. 16: Extensive description of machine and outline of its development. Dec. 23: Oiling system; electric ignition; voltage regulator; duplex Zenith carburetor.

Starter

The Liberty Starter. Aerial Age, vol. 8, no. 16, Dec. 30, 1918, p. 816, 3 figs. Elevation and sections of 4-cylinder radial 2-cycle air motor. As starter it has a 9 to 1 gear reduction on final drive to motor.

HISTORY

Official U. S. History

Official History of Aircraft Production. Automotive Indus., vol. 39, no. 23, Dec. 5, 1918, pp. 968-969 and 987-990. Objects, problems, production, and results of air program.

MATERIALS OF CONSTRUCTION

Spruce

Development of the Aircraft Spruce Industry. Lawrence K. Hodges. Automotive Indus., vol. 39, nos. 25 and 26, Dec. 19 and 26, 1918, pp. 1037-1040 and 1100-1101, 8 figs. Organization of Spruce Production Division. Figures of monthly cut; problem of by-products disposal.

See also MECHANICAL ENGINEERING, Corrosion (Aircraft Parts).

METEOROLOGY

Aerographic Records

Uniformity in Aerographic Records. Alexander McAdie. Sci. Am. Supp., vol. 87, no. 2244, Jan. 4, 1919, pp. 15-16. Discusses desirability of universal scientific units. Special reference is made to meteorological work.

MODELS

Ford-Motored Aeroplane

Elementary Aeronautics and Model Notes. John F. McMahon. Aerial Age, vol. 8, no. 14, Dec 16, 1918, p. 727, 16 figs. Construction of a Ford-motored airplane.

Model Construction

Model Aeroplane Building as a Step to Aeronautic Engineering. Aerial Age, vol. 8, nos. 11, 12, 15 and 16, Nov. 25, Dec. 2, 23 and 30, 1918, pp. 581, 627, 781 and 826, 16 figs. Table of resistance and weight of spruce struts. Table of plates of different aspect ratios at angles from 5 to 60 deg. showing K_y, K_x and ratio of lift to drift at the different angles. Bracing fuselage. Construction of seat, gas tank and rudder bar.

PLANES

Berg

The Austrian Berg Single-Seater. Flight, vol. 10, no. 46, Nov. 14, 1918, pp. 1285-1287, 9 figs. Wing section; attachment of struts to fuselage and longerons; details of internal bracing; ailerons. (Concluded.)

Bombers

The Gotha Bomber, with Notes on Giant Aeroplanes. Flight, vol. 10, nos. 46, 47, 48 and 49, Nov. 14, 21, 28 and Dec. 5, 1918, pp. 1280-1282, 1318-1322, 1340-1347 and 1375-1378, 84 figs. Nov. 14: Principal dimensions; construction; struts; ailerons; propeller accommodation; empennage; fuselage. Nov. 21: Undercarriage; engine mounting; engines; controls; petrol system; armament; bombs; wireless; instruments; fabric and dope. Nov. 28: Particulars of four-engined giant. Dec. 5: Principal items of interest in five-engined giant brought down by allied forces. Issued by Technical Department, Aircraft Production, Ministry of Munitions. Also Engineer, vol. 126, no. 3281, Nov. 15, 1918, pp. 419-421, 8 figs.; Aeronautics, vol. 15, no. 266, Nov. 20, 1918, pp. 473-486, 79 figs.

De Haviland 4

The De Haviland 4, with Liberty "12" Engine. Aerial Age, vol. 8, no. 17, Jan. 6, 1918, pp. 860-861, 5 figs. General dimensions and weights.

Design

The Probable Trend of Aeroplane Design. R. F. Mann. Sci. Am. Supp., vol. 87, no. 2244, Jan. 4, 1919, p. 11, 1 fig. Review of present stage in development and changes likely to be introduced by reason of applications of airplanes to various purposes. From Flight.

The Trend of German Aeroplane Design. Flight, vol. 10, no. 49, Dec. 5, 1918, pp. 1383-1385. Comparison with British machine of principal features of captured German aeroplanes. Also in Aeronautics, vol. 15, no. 268, Dec. 4, 1918, pp. 518-520.

Gallaudet

The Gallaudet D-4 Light Bomber Seaplane. Aerial Age, vol. 8, no. 16, Dec. 30, 1918, pp. 817 and 831, 3 figs. General specifications. Machine is a biplane and is fitted with one 400-hp. Liberty "Twelve" engine.

Hannoveraner

The German Airplane Hannoveraner, C. L. II. (Avion allemand Hannoveraner C. L. III). Aérophile, year 26, nos. 19 and 20, Oct. 1-15, 1918, pp. 289-296, 10 figs. Comprehensive de-description of light biplane fitted with 200-hp. Opel motor.

Junker

The Junker Armored Biplane. Flight, vol. 10, no. 48, Nov. 28, 1918, pp. 1356-1357, 2 figs. Main characteristics of all-metal aeroplane.

L-W-F

The L-W-F Model G-2 Fighting Airplane. Glenn D. Mitchell. Aviation, vol. 5, no. 9, Dec. 1, 1918, pp. 554-558, 7 figs. General features and dimensions of an all-American design.

Martin

The Martin K-III Single Seater. Aerial Age, vol. 8, no. 15, Dec. 23, 1918, pp. 759-761, 7 figs. Particulars of biplane specially designed as altitude fighter and equipped with oxygen tanks and provision for electrically heating pilot's clothing.

N. C. 1, U. S. Navy

Our Giant Aircraft. Sci. Am., vol. 120, no. 1, Jan. 4, 1919, pp. 7 and 18. General design of N. C. 1 equipped with three 12-cylinder Liberty engines driving three four-bladed tractor screws; wing spread, 126 ft.

Rumpler

Rumpler Two-Seater Biplane. Automotive Indus., vol. 39, no. 23, Dec. 5, 1918, pp. 962-965, 14 figs. Technical description of model German reconnaissance machine. Issued by British Aircraft Department.

PROPELLERS

Metal

The Metal Airscrew. Vladimir Olhovsky. Aerial Age, vol. 8, no. 12, Dec. 2, 1918, pp. 622-623, 2 figs. Results of experiments on wooden and metal propellers; factors entering in design of hollow metal propeller.

Patterns

Propeller Patterns. Joseph A. Shelly. Machy., vol. 25, no. 5, Jan. 1919, pp. 434-438, 8 figs. Describes method of laying out propeller patterns, assembling different sections and working blades to required form. (Second article.)

Research

Experimental Research on Air Propellers, II. William F. Durand. Automotive Eng., vol. 3, no. 10, Dec. 1918, pp. 478-480, 2 figs. Results of work done by Nat. Advisory Committee for Aeronautics. Torque dynamometer; revolution counter; air-speed meter; tests and calibrations of apparatus; uniformity of velocity over cross-section of air stream; relation between depression within experiment room and air stream velocity. (To be concluded.)

Marine Engineering

AUXILIARY EQUIPMENT

Barge

Standard Concrete Barge for Use on the New York State Barge Canal. Engineering, vol. 106, no. 2759, Nov. 15, 1918, pp. 554-556, 6 figs. Drawings showing details of construction.

Starrett
A Few of the Many Styles and Sizes of
Starrett Tools
MANUFACTURERS, toolmakers, machinists, inspectors and mechanics in all trades recognize the Starrett Tools as Standards for accuracy, an assurance that comes through the knowledge that tools bearing the "Starrett" name are guaranteed.
There are tools to meet every practical requirement described in our catalog No. 21—write for your copy. It also shows Starrett Hack Saws that cut quicker and last longer.
THE L. S. STARRETT COMPANY
The World's Greatest Toolmakers
Manufacturers of Hacksaws Unexcelled
ATHOL, MASS., U. S. A.
NEW YORK LONDON CHICAGO
42-839
STARRETT TOOLS
The STARRETT BOOK

Bark, Auxiliary

Auxiliary Bark—The France, George Douglas. Rudder, vol. 34, no. 12, Dec. 1918, pp. 590-592, 5 figs. Sail plan, deck arrangement and design features of five-masted bark, 418.8 ft. long, fitted with two Schneider heavy-oil engines.

Fishing Cruiser

An Outdoor Motored Cruiser—Complete Plans and Building Instructions, William Atkin. Motor Boat, vol. 15, no. 23, 6 figs. Model is adaptation of flat-bottomed work boats used by clammers of Lower New York Bay.

Life Boats

Two Lifeboats in Place of One. Rudder, vol. 34, no. 12, Dec. 1918, pp. 588-590, 7 figs. Design providing partial collapse of one so it can be stowed under the other.

Producer-Gas Power Lighter

Design and Construction of Producer Gas Power Lighter, Frederick S. Nock. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 36-37, 3 figs. Special central control for engine and hoisting apparatus; double rudder installation; compact engine-room planning.

Towboat

Plans and Specifications of New Wood Tow Boats. Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 673-674, 2 figs. Built for hard service; compound engine of 750 hp.; Scotch boiler with three Morison furnaces.

SALVAGE

Salving of the SS. "——— ," Frank A. T. Wheeler. Tran. Inst. Marine Engrs., vol. 30, no. 238, Oct. 1918, pp. 218-220, 3 figs. Steps taken to prevent falling over of vessel struck by torpedo on her port side in No. 5 hole, holes being blown in her 'tween deck and starboard side; watertight bulkhead at after end of engine room leaked badly and eventually flooded engine room.

SHIPS

Boilers

Sediment in Marine Boilers, Its Bearing on Furnace Collapse, W. R. Austin. Trans. Inst. Marine Engrs., vol. 30, no. 238, Oct. 1918, pp. 189-196, 1 fig. and (discussion), pp. 196-209. Occasions where risk arises and suggestions to eliminate it; Backing strains from unequal expansion and their prevention by keeping uniform temperature in furnaces; dangers arising from circulation of sediment caused by rolling of ship; possibilities of creating critical situation while cleaning a fire at sea; means of avoiding accident while lying under banked fires.

Concrete Ship

What the Year Has Taught About the Concrete Ship. Eng. News-Rec., vol. 82, no. 1, Jan. 1, 1919, pp. 14-15. Much learned regarding design and construction; future depends on ability to build in cost competition with steel; structurally, ship is success.

Concrete Ships and Barges (Los buques i barcos menores de concreto). Boletin de la Sociedad de Fomento Fabril, year 35, no. 9, Sept. 1918, pp. 614-619. History of development of process from 1849 to present time.

Shear in Concrete Ships Critical Point in Design, A. C. Janni. Eng. News-Rec., vol. 81, no. 24, Dec. 12, 1918, pp. 1089-1091, 1 fig. According to accepted theory, usual thin shell monolithic with frame gives rise to dangerous conditions.

Design

V-Bottom or Round Bilge—Which? George F. Crouch. Motor Boat, vol. 15, no. 23, Dec. 10, 1918, pp. 30-34, 3 figs. Advantages of each shape; diagrams showing relations between length and speed, and giving approximate form to use for different speeds.

Best Fore-and-Aft Position of Parallel Middle Body in Single-Screw Cargo Ship, William McEntee. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 18-23, 8 figs. Effect of variation of position of parallel middle body on shaft horsepower, propulsion coefficient and propeller revolutions. Paper before Soc. of Naval Architects and Marine Eng., Philadelphia, Nov. 1918.

Electric Transmission

Electric Propulsion of Vessels (La propulsion électrique des navires), A. Foillard. Génie Civil, vol. 73, no. 17, Oct. 26, 1918, pp. 321-327, 13 figs. Machinery used and characteristic curves of motors in the vessels Wulsty Castle and Mjölner.

Lubrication

Uniform and Constant Forced-Feed Lubrication of the Steamchests, Cylinders and Other Parts of Steam Engines. Ry. Engr., vol. 39, no. 466, Nov. 1918, pp. 203-209, 8 figs. Describes "Intensifore" Gorton type developed from exhaustive experiments with various mechanical and hydrostatic lubricators by engineering staff of Great Central Ry.

Power Plant

Marine Power Units, J. G. Callan. Wis. Engr., vol. 23, no. 2, Nov. 1918, pp. 42-47. General characteristics of steam turbines and Diesel engines. Reasonableness of adoption of geared unit.

Standards

Adopt British Ship Steel Standards. Iron Trade Rev., vol. 63, no. 22, Nov. 28, 1918, pp. 1245-1246. Decisions of American steel manufacturers at conference in Philadelphia.

Standardization of Ship Steel. Steel & Metal Digest, vol. 8, no. 12, Dec. 1918, pp. 690-691. Recommendation of mills to Emergency Fleet Corporation.

Structural Steel Standardization Cargo Vessels, Henry R. Sutphen. Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 695-698, 1 fig. How quantity production was met; use of structural steel expedient; layout of yard.

Submarines

The Surrender of the Submarines. Min. Jl., vol. 123, no. 4345, Nov. 30, 1918, pp. 688-691, 5 figs. General features of construction of the different types, their propulsive machinery and other engineering details.

See also MECHANICAL ENGINEERING, *Internal Combustion Engines* (*Winton Marine Engine*).

YARDS

Concrete Vessels

Build Boats in Dry Docks at New Yards in Detroit. Eng. News-Rec., vol. 82, no. 1, Jan. 2, 1919, pp. 21-24, 9 figs. Concrete barges under construction on concrete floors inside dikes which will be flooded for launching; lighters carry construction machinery alongside dry docks.

Reinforced Concrete Shipbuilding in Dorsetshire. Engineer, vol. 126, no. 3281, Nov. 15, 1918, pp. 408-410, 10 figs. Drawings with description of some concrete ships.

Building a Government 3500-Ton Concrete Ship. Eng. News-Rec., vol. 81, no. 24, Dec. 12, 1918, pp. 1058-1065, 16 figs. Fougner yard has concrete ways; reinforcement tacked to outside forms and finish put on with cement gun; air hammers on forms compact concrete.

Control of Construction

Control of the Construction of a 5000-Ton Deadweight Fabricated Steel Ship, "Fabricator." Int. Mar. Eng., vol. 23, no. 12, and vol. 24, no. 1, Dec. 1918 and Jan. 1919, pp. 691-694 and pp. 29-30, 6 figs. Dec. 1918: Special schedule for ordering and installation of machinery and equipment; correlation between order and purchasing departments. (Fourth article.) Jan. 1919: Forms for following up movement and arrival of steel parts; railway shipments of plates and sheets traced. (Fifth article.)

Costs and Estimates

Shipbuilding Costs and Estimates, James M. Robertson. Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 671-672. Careful reading of specifications necessary; system a requisite; list of items; how to deal with individual items. (Second article.)

Cranes

Pre-Assembly System and Efficient Erection Cranes Speed Up Shipbuilding at Ecorse. Eng. News-Rec., vol. 81, no. 24, Dec. 12, 1918, pp. 1076-1081, 8 figs. Pre-assembling extending rapidly in Lake Yards; reduces erection labor on hulls.

Design

Berth Construction and Side-Launching Practice in Great Lakes Shipyards. Eng. News-Rec., vol. 82, no. 1, Jan. 2, 1919, pp. 7-13, 25 figs. Berth structure simple; timber and concrete foundations for support of ships; concrete launching-way stringers at one yard; keel blocks and cradles variously arranged; trip shores to release ships.

Ship-Design and Quantity-Production Methods of Newark Bay Yard. Eng. News-Rec., vol. 81, no. 25, Dec. 19, 1918, pp. 1122-1125, 4 figs. Project for factory-style shipbuilding based on enlisting new labor supply and using commercial steel; methods dictated by delay in ship orders; bridge shops fabricate straight parts.

Equipment

Fabricating Shop and Berth Equipment at Sun Shipyard. Eng. News-Rec., vol. 82, no. 1, Jan. 1, 1919, pp. 57-61, 9 figs. Assembly bay of shop delivers finished material to shipbuilding cranes; multiple punches and roller tables; reinforced-concrete berths served by bridge cranes.

Fabricated Ship

Fabricated-Ship Construction in One Year's Experience. Eng. News-Rec., vol. 82, no. 1, Jan. 2, 1919, pp. 16-17. New system now tested by large-scale working has proved adaptable and free from inherent difficulties or elements of excess cost.

Ford Eagles

Building the Ford Submarine-Chaser "Eagle." Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 23-27, 7 figs. Simplicity of hull construction; safety devices on unusual launching platform; routing aids production.

Ford Methods in Ship Manufacture, Fred E. Rogers. Ind. Management, vol. 57, no. 1, Jan. 1919, pp. 1-6, 12 figs. Description of boat with features of plan of manufacture. (First article.)

Building the Ford Submarine Chaser "Eagle." Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 702-705, 4 figs. Straight-line design; two parts of system; hurried development of process.

Hog Island

Hog Island, the Greatest Shipyard in the World, W. H. Blood, Jr. Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 678-690, 20 figs. Review of conditions that preceded planning of yard; adopting type and design of boat; troubles encountered and overcome. Before Soc. of Naval Architects and Marine Engrs., Philadelphia, Nov. 1918.

Illumination

A Method of Ship Way Illumination, F. D. Weber. Jl. Elec., vol. 41, no. 11, Dec. 1, 1918, p. 503. Outlines method followed by western company.

Laying Out

Laying Down and Taking Off, Charles Desmond. Rudder, vol. 34, no. 12, Dec. 1918, pp. 584-587, 5 figs. How to lay out shape of transom stern inclined aft with rounded after face and intended to be made of pieces of material bent to shape. (Continuation of serial.)

New Yards

Large Addition to Plant of the Tidewater Shipbuilders, Ltd., Cap de la Madeleine, P. Q. Contract Rec., vol. 32, no. 51, Dec. 18, 1918, pp. 1001-1004, 6 figs. Extensions necessitated to build four 5100-ton steel cargo boats.

Shipbuilding at the Pensacola Yards, John M. Sweeney. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 12-16, 8 figs. Well-constructed plant for 9000-ton fabricated steel ship; use of permanent scaffolding; powerful plate-bending machine.

Routing of Materials

Routing of Fabricated Ship Material at Bristol. Eng. News-Rec., vol. 82, no. 1, Jan. 2, 1919, pp. 25-30, 9 figs. Hull construction operated on basis of shop-to-storage-to-ship system requires accurate timing of material supply, shop work, and assembly; routing handled by production department.

Welding

The Steel Ship and Oxy-Acetylene Welding, J. F. Springer. Can. Machy., vol. 20, no. 25, Dec. 19, 1918, pp. 701-703. Observations on behavior of metal under welding flame and precautions to be taken. Writer believes tensile strength of material at and near weld is much less than that of the plates. Of the restorative measures available, he considers reheating method the most convenient and effective.

Welding Designs for Shipyard Use, E. G. Rigby. Marine Rev., vol. 49, no. 1, Jan. 1919, pp. 22-29, 22 figs. Practical examples of electric welding in deck, tank and bulkhead structures; how it is applied to armor plate.

Electric Welding in Ship Construction, H. Jasper Cox. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 42-46, 7 figs. Methods of welding and apparatus described; inspection and testing welds; speed and cost of welding; Lloyd's experiments. Paper before Soc. of Naval Architects and Mar. Eng., Philadelphia, Nov. 1918.

The Steel Ship and Oxy-Acetylene Welding, J. F. Springer. Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 699-701. Autogenous welding decreases strength of steel; behavior under heat; restorative measures.

The First Electrically Welded Boat, John Liston. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 844-848, 10 figs. Process followed in welding 42-ft. boat of 11-ft. beam said to have been plying Lake Erie for two years when the 275-ton, English-built, rivetless welded barge was launched in June 1918.

Electric Welding for Shipbuilding. Elecn., vol. 81, no. 2114, Nov. 22, 1918, pp. 619-620. From address by W. S. Abell, Chief Ship Surveyor of Lloyd's Register, before North-East Coast Inst. of Engrs. and Shipbuilders, Tyneside, Nov. 1918.

U. S. Warship Kept on the Job by Oxy-Acetylene Torch. Jl. Acetylene Welding, vol. 20, no. 6, Dec. 1918, pp. 290 and 292. Repair of boiler with oxy-acetylene outfit.

Electric Welding for Shipbuilding, W. S. Abell. Nautical Gaz., vol. 94, no. 24, Dec. 14,

1918, pp. 346-347. Past progress; strength of joints; possibility of industry. Paper before British Northeast Coast Instn. Engrs. & Shipbuilders.

The Adequacy of Welding in Constructing Hulls of Ships, H. M. Hobart. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 840-845. Investigations of Welding Research Sub-Committee of Emergency Fleet Corporation in regard to relative merits of different systems and equipments.

Spot Welding and Some of Its Applications to Ship Construction, H. A. Winne. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 923-927, 6 figs. Advantages of spot welding over riveting with respect to strength, time, and labor; limitations of spot welder; application of spot welding to construction of ladders and gratings and to plugging of misplaced holes.

Electric Welding in Navy Yards, H. G. Knox. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 849-859, 20 figs. Work conducted in each type of shop in a navy yard; recommendations of welding equipment desirable in each shop; data on speed and cost of welding ship structures; comparative cost data of welding based on records from steam railroads.

The Electric Arc Used in Steamship Overhauling. Can. Machy., vol. 20, no. 24, Dec. 12, 1918, pp. 675-676, 2 figs. Examples of uses of Westinghouse arc welder in repairing marine boiler and furnace while under steam.

Arc Welding in Shipyard, W. L. Roberts. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 860-864, 13 figs. Simplification of anglesmith's work by use of arc welding in production of staples; probability of abandoning staples in favor of directly arc-welding parts; application of electric arc to construction of water, oil, and air tanks, stacks, condensers, and other similar appliances.

Wooden Vessels

Building Wooden Vessels on the Pacific. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 8-11, 8 figs. Record of accomplishment; Hough and Ferris types give way to 5000-ton vessels; wood vessels coming into their own again.

VARIA

Emergency Fleet Corporation

Organization of the U. S. Shipping Board Emergency Fleet Corporation, Charles Piez. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 32-35, 2 figs. Relationship and functions of Board and construction and operation divisions of Fleet Corporation.

Naval Engineering in War

The Achievements of Naval Engineering in the War, William L. Cathcart. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 18-25, 18 figs. Organizations and principal activities of Bureau of Steam Engineering; electric drive for battleships; repair of German merchant ships by oxy-acetylene welding. Presented at annual meeting of Society.

U. S. Shipbuilding in 1918

Shipbuilding in the United States in 1918. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 5-7. Three million tons of merchant ship completed in first eleven months; rate of production rapidly increasing.

Organization and Management

ACCOUNTING

Expense Distribution

Efficiency and Democracy, H. L. Gantt. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, p. 43. Suggestions in regard to accounting systems. Stress is laid on erroneous process of charging work with expense of idle machines.

EDUCATION

Apprentices

The Training of Engineering Apprentices, T. H. Fenner. Can. Machy., vol. 20, no. 23, Dec. 5, 1918, pp. 641-643, 4 figs. Analyzes necessary standard of education and suggests course of training.

Canada

Labor, Apprenticeship and Technical Education. Can. Engr., vol. 35, no. 24, Dec. 12, 1918, p. 511. Report of committee to Ottawa Conference of Assn. of Can. Building and Construction Industries.

Crippled Workers

How to Deal with Crippled Workers, T. Norman Dean. Am. Mach., vol. 49, no. 25, Dec. 19, 1918, pp. 1115-1116. Suggestions from deductions from scientific experience to relieve 2,122,000 industrial cripples in United States.

Physical Reconstruction of Crippled Men, Constance Drexel. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 508-509. Plan of U. S. Government for rehabilitation and vocational training; schools established giving courses in oxy-acetylene welding, etc.

Re-Educated Soldiers in the Machine Trade, Katherine Freeman. Can. Machy., vol. 20, no. 25, Dec. 1918, pp. 691-692, 2 figs. Instances in which vocational reëducation, together with artificial limbs, have made injured soldiers earn more than in pre-war days.

Industrial Surveys for Physical Readjustment, A. B. Segur. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 63-65, 2 figs. Method of investigating possibilities of employing disabled persons in industry, developed by Red Cross Institute for the Blind; results shown for few operations in a meat-packing house.

Engineers

The Engineer in Foreign Service, L. S. Rowe. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 31-32. Plea to broaden training of engineer in order that he may acquire a greater breadth of view which will permit his adaptability to international service.

English Language

Educational in English Language Promotes Efficiency, Sarah Elkus. Nat. Efficiency Quarterly, vol. 1, no. 3, Nov. 1918, pp. 140-149. Coöperation of Board of Education in promoting English classes in factories; English as a safety-first method.

S. A. T. C.

Students' Army Training Corps, Alexander S. Langsdorf. Proc. St. Louis Ry Club, vol. 23, no. 7, Nov. 22, 1918, pp. 115-127 and (discussion) pp. 127-129. Educational plan as developed by War Department after series of experiments. Special reference made to features and arrangements of Government contracts with Washington University.

Intensive Training, C. R. Dooley. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 37-38. Program set up by Committee on Education and Special Training. It consisted of (1) military training, (2) sorting and training according to ability, (3) trade fundamentals and combinations, and (4) development of originality and initiative.

Shipyards

Industrial Training in War Time, E. E. MacNary. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 871-875, 4 figs. Procedure followed and accomplishments performed by Emergency Fleet Corporation. Article deals with teaching of eighteen different trades.

Training 350,000 Men for the Shipyards, J. Will Parry. Eng. News-Rec., vol. 82, no. 1, Jan. 1, 1919, pp. 53-56, 1 fig. How Fleet Corporation met problem.

Training Workers in Shipyards, R. V. Rickford. Int. Mar. Eng., vol. 24, no. 1, Jan. 1919, pp. 38-42, 12 figs. Short cut over old apprentice system; work progresses from simple to difficult operations; rivet records show results.

Trade Journals

Technical Journal Best Aid to Education, S. Balmfirth. Can. Foundryman, vol. 9, no. 12, Dec. 1918, pp. 307-309. After analyzing advantages and disadvantages of various sources of technical education writer concludes that technical journals, by reason of their ready availability and simplicity of style, are best help for self-instruction. Also in Can. Machy., vol. 20, no. 23, Dec. 5, 1918, pp. 655 and 657.

Training Factory

Lens Grinding in a Training Factory, Erik Oberg. Machy., vol. 25, no. 4, Dec. 1918, pp. 330-332, 3 figs. Means for meeting war emergencies devised by U. S. Government.

Vocational Schools

Need for vocational Schools in Mining Communities, J. C. Wright. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 91-94. Kinds of vocational schools which may be organized under the terms of the Federal Vocational Education Act.

Welders

The Training of Electric Welders, H. A. Horner. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 876-881, 9 figs. Development of ingenuity and manipulating skill necessitated by welding operators said to be principal aim of course given by instructors of Emergency Fleet Corporation.

Women

Service for Women in the Gisholt Shop, J. V. Hunter. Am. Mach., vol. 50, no. 1, Jan. 2, 1919, pp. 6-10, 17 figs. Methods used in training women workers in a Wisconsin shop.

Preliminary Training for Women Workers, Fred H. Colvin. Am. Mach., vol. 49, no. 24, Dec. 12, 1918, pp. 1067-1070, 9 figs. Account of methods employed in school of Packard Motor Car Co.

Motor Company's Shop Training for Women, F. L. Prentiss. Iron Age, vol. 102, no. 24, Dec. 12, 1918, pp. 1453-1455, 1 fig. Intensive work at Lincoln plant done in threshold school; women employees are protected by enforcement of rigid rules.

Work Schools

New Developments in Industrial Organization, Modern Methods of Port Sunlight (Ill.), W. G. Cass. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 248-256. Work schools at Port Sunlight works.

FACTORY MANAGEMENT

Employment Managers

Aids to Employment Managers and Interviewers on Shipyard Occupations with Description of Such Occupations. Special Bul. U. S. Shipping Board Emergency Fleet Corporation, 1918, 147 pp. List of fundamental trades and occupations with most commonly accepted names used as standard. Specifications describe occupation from shipyard standpoint.

Duties of the Employment Manager, Charles W. Moon. Machy., vol. 25, no. 5, Jan. 1919, pp. 443-447, 9 figs. Fundamental principles involved and methods used successfully by R. K. Le Blond Machine Tool Co.

Employment Managers Graduate at the University of California, A. T. Parsons. Metal Trades, vol. 9, no. 11, Nov. 1918, pp. 450-452. Historical account of development of industrial activity involved in occupation of employment managers.

Handbook on Employment Management in the Shipyard. Organizing the Employment Department—I. U. S. Shipping Board Emergency Fleet Corporation 1918, 17 pp. Methods and processes of handling employment problems, which have been found successful in some of largest shipyards and corporations in U. S.

The Employment Manager a New Factor in the Industrial Relationship, Edward D. Jones. Wis. Engr., vol. 23, no. 2, Nov. 1918, pp. 48-53. Considerations on necessity for and meaning of formanizing labor as developed in new profession. Also in Metal Trades, vol. 9, no. 12, Dec. 1918, pp. 500-501.

Employment Methods

Installing Employment Methods, William Alfred Sawyer. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 7-11, 16 figs. Record of first year's work of employment and health department of American Pulley Co.

Interviewing and Selecting, Mark M. Jones. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 66-67. From address before Am. Assn. of Public Employment Officers.

Environment

Influence of Environment on Production, Lewis J. Brew. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 428-429. Suggestions in layout and details of forge plant.

Equipment

Equipment for Diversified Production, A. B. Shuart. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 429-430. Features of forge-plant design contributing to eliminate manual labor to large extent.

Ford Shipbuilding Methods

Ford Methods in Ship Manufacture—I, Fred E. Rogers. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 1-6, 12 figs. Basic features that made possible the production of Eagle submarine chasers. (To be continued.)

Foundry

Organizing a Foundry to Obtain Top Production, Paul R. Ramp. Foundry, vol. 47, no. 317, Jan. 1919, pp. 8-13, 5 figs. Systematic method of following up work of foremen in each department essential. From paper before Am. Foundrymen's Assn., Milwaukee.

Inter-Departmental Communications

Shooting the Shop Orders to Their Targets, Robert L. Clegg. Iron Age, vol. 103, no. 1, Jan. 2, 1919, pp. 53-55, 4 figs. Simple scheme of Geometric Tool Co. to rush instructions to departments the instant they are required.

Localization of Industry

The Localization of Industry, Malcolm Keir. Sci. Monthly, vol. 8, no. 1, Jan. 1919, pp. 32-48. Localization traceable as response to resources either in raw materials and power, or in unskilled labor; chance and monopoly as contributing factors; requirements of factories utilizing waste products; dependence of localized industries on skilled labor; influence of localization in formation of labor unions; deterrent features of localization.

Material Handling

Saving Tool Materials in Winchester Shop, W. E. Freeland. Iron Age, vol. 102, no. 26, Dec. 26, 1918, pp. 1574-1575, 2 figs. Work of central material planning division. Files are kept on steel basis. Tenth article dealing with methods at Winchester plant.

Organization

What Should Organization Achieve? Harry Tipper. Automotive Indus., vol. 40, no. 1, Jan. 2, 1919, pp. 17-18. Its effect on (1) providing incentive to work, (2) settling individual grievances and general disagreements, (3) improving the working force, (4) decreasing labor turnover, and (5) reducing friction between departments.

Production Control

Graphic Production Control—V The Control of Equipment and Labor, C. E. Knoeppel, Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 56-62, 22 figs. Features of control said to improve efficiency of workmen, do away with idleness of equipment and improve faulty shop practice. (To be concluded.)

Public-Utility Plants

Practical Measures for Securing Greatest Economy in Public Utility Plant Operation, Charles Brossman. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 206-208. Proper use of recording and indicating instruments; bonus system; examples of plant neglect.

Purchasing

Principles of Purchasing and Storing, Dwight T. Farnham. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 33-38, 6 figs. Instructions concerning storing of materials and supplies, their withdrawal from stock, preparing purchasing requisitions, obtaining bids and quotations, placing purchase orders, following up delayed purchase materials, and reporting receipt of materials. From U. S. Employment Service Bulletin.

Rates and Rate Setting

Time Studies for Rate Setting on Gisholt Boring Mills (III), Dwight V. Merrick. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 271-275, 4 figs. Time required in actual manipulation of machine for cuts.

Establishing Basic Rates Saves Time Study Work, Carle M. Bigelow. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 17-22, 5 figs. Using as examples the determination of basic rate for a machine and finding basic rate for manual labor, writer points out how their use gradually increases usefulness of time-study men by simplifying vexatious problems of determining allowed times and repeated studies due to variation of product for single operation.

Shop Efficiency

The Cultivation of Shop Efficiency, H. J. MacMillan. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 446-447, 9 figs. Contrasts present with past conditions in industrial relationship between employees. In illustration quotes work accomplished by Mueller Mfg. Co.

Tool System

A Simple Tool System, B. L. Van Schaick. Indus. Management, vol. 57, no. 1, Jan. 1919, p. 32, 1 fig. Plan based on actual inventory and formation of central crib where all grinding, dressing and repairing is done.

FINANCE AND COST

Cost Accounting

Cost Accounting to Aid Production IV. The Principles of Burden Distribution, G. Charter Harrison. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 49-55, 2 figs. Details of method of obtaining machine rates, bringing in use of punched cards and sorting and tabulating machines. (To be continued.)

Cost Finding

True Cost Finding What It Can Do for the Railroads, Morris Llewellyn Cooke. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 40-42. States that since main purpose in collecting cost data is to measure efficiency, its scientific application in railroad operation will provide gage for efficiency of each performance; and that initiative in scheming out an adequate cost finding system should be taken by U. S. Railroad Administration.

Cost Systems at Factories

Costing at National Factories, W. Webster Jenkinson. Iron & Coal Trades Rev., vol. 47, no. 2645, Nov. 8, 1918, pp. 513-516. Forms of progress records and cost returns; desirability of introducing cost system in a business. (Concluded.)

Cost Systems, Construction

How to Figure Construction Costs, Stanley D. Moore. Cement & Eng. News, vol. 30, no. 12, Dec. 1918, pp. 30-32. Notes on calculation of sewer system costs. Address at annual meeting of Iowa Eng. Soc.

INSPECTION

Fuel Supervision

Supervision and Fuel Economy, Robert Collett. Official Proc. N. Y. R. R. Club, vol. 29, no. 1, Dec. 1918, pp. 5452-5455. Recommends supervision by friendly counsel and encouragement.

LABOR

Bonuses

Day Labor, Force Account Work and Bonuses, Charles M. Upham. Good Roads, vol. 16, no. 25, Dec. 21, 1918, pp. 239-241. Discusses advantages and disadvantages. Paper presented at meeting of Am. Assn. State Highway Officials, Chicago.

Piece Work and Bonus System (Le travail aux pièces et la prime), M. Crémieux. Génie Civil, vol. 73, no. 17, Oct. 26, 1918, pp. 329-333, 8 figs. Established fundamental equations for comparison of these two systems of remunerating workers.

Compensation

Workmen's Compensation, Health Insurance and Hospitals, Thomas Howell. Modern Hospital, vol 11, no. 5, Nov. 1918, pp. 414-416. Discussion of future relations of charitable hospitals to industry, indicating probable vast changes.

Cripples

An Experimental Employment Bureau for Cripples, Eleanor Adler, Modern Hospital, vol. 11, no. 5, Nov. 1918, pp. 402-405. Brief historical account of efforts to find employment for disabled with reference to establishment of bureau under control of Federation of Assns. for Cripples and the Hudson Guild.

Opportunities for Crippled Soldiers in the Metal Industries, Elsie Plant. Metal Trades, vol. 9, no. 11, Nov. 1918, pp. 448-449, 3 figs. Some of the things disabled men can do, as found by Red Cross Inst. for Crippled and Disabled Men.

Demobilization

When Labor Comes to Market, Walton H. Hamilton. Survey, vol. 41, no. 14, Jan. 4, 1919, pp. 425-428. Explanation and comment on demobilization chart of U. S. Labor Policies Board showing importance of rate at which demobilization is to be effected, analysis of problem and contingencies upon which solution depends.

Status of the Unproductive Worker, Harry Tipper. Automotive Indus., vol. 39, no. 25, Dec. 1918, pp. 1045-1046. Right of salaried workers to representation in organization with skilled and unskilled employees.

Employment Department

Employment Department, Hog Island Shipyard. Am. Mach., vol. 49, no. 23, Dec. 12, 1918, pp. 1071-1075, 11 figs. Shows forms used and describes process of employing men.

A Definition of "Penny-Wise, Pound Foolish," Applied to the Picking and Developing of Men for Big Jobs, Christian Girl. Monthly Jl. Utah Soc. Engrs., vol. 4, no. 9, Sept. 1918, pp. 169-175. Analysis of characteristics in personnel which contribute to stability of organization. Experience of writer in picking out men. From System.

Selecting Employees. Gas Industry, vol. 18, no. 12, Dec. 1918, pp. 359-362. Forms used by company covering appearance, mentality, and ability of applicants, who are examined on each by different person.

Housing

Instances of Industrial Housing. Stone & Webster Jl., vol. 23, no. 6, Dec. 1918, pp. 408-413, 11 figs. General appearance and finish of industrial housing at Mills of Carnegie Steel Co., and Buckeye Coal Co. Developments include building of houses, grading of streets, installation of water and sewer lines, etc.

The New E. F. C. Hotel at Hog Island, W. H. Blood. Stone & Webster Jl., vol. 23, no. 5, Nov. 1918, pp. 344-346, 4 figs. Views; rules; conveniences available. Hotel accommodates 2176 men.

Industrial Courts

New Basis for Industrial Relations, Harry P. Kendall. Am. Contractor, vol. 39, no. 52, Dec. 28, 1918, p. 17. Discusses establishment of set of federal industrial courts as in Australia, and formation of boards set up by workmen and their employees with equal representation on each side to determine standards of wages, hours and conditions of employment. Address before Nat. Councillors of Chamber of Commerce of U. S.

Labor Representation

How Labor Representation Operates. Iron Trade Rev., vol. 63, no. 24, Dec. 12, 1918, pp. 1349-1351. Presents plan adopted by Youngstown Sheet & Tube Co., in which the company commits itself to whatever may be declared to be just and equitable.

Political Plan of Organization Satisfactory for Relatively Small Establishments, Harry Tipper. Automotive Indus., vol. 39, no. 26, Dec. 26, 1918, pp. 1083-1084 and 1088. Combined work of employees' representatives and supervisors' committee.

Real Labor Representation, Harry Tipper. Automotive Indus., vol. 39, no. 24, Dec. 12, 1918, pp. 1006-1007 and 1010, 1 fig. Analysis of Midvale Steel & Ordnance Co.'s plan. Organization constituted of legislative and judicial committees elected by employees in the various plants.

Labor Situation

What About Labor? Business Digest & Investment Weekly, vol. 22, no. 12, Dec. 17, 1918, pp. 421-423 and 429. Reasons why, despite resumption of normal business activity, there is hesitancy due to possibilities in labor situation.

Mine Labor

Employment of Mine Labor, Herbert M. Wilson. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. 83-85. Important aspects of securing and retaining workmen; purpose of Federal Board for Vocational Education.

Piece-Rate Card System

Layout and Piece-Rate Card System, John J. Borkenhagen. Machy., vol. 25, no. 4, Dec. 1918, pp. 327-329, 13 figs. Forms that assist in efficiency shop management.

Relations Between Employees

A Unique Method of Handling Employees. Jl. Elec., vol. 41, no. 10, Nov. 15, 1918, pp. 443-444. Promoting activities which will foster social relationship between them.

The Human Touch in Supervision, E. C. Clarke. Elec. Ry. Jl., vol. 52, no. 24, Dec. 14, 1918, 1048-1050, 3 figs. Object of management should be to instill spirit of coöperation among employees; how it may be done.

Wages

The Relation of Wages to Public Health, B. S. Warren and Edgar Sydenstricker. Am. Jl. Public Health, vol. 8, no. 12, Dec. 1918, pp. 883-887. Points out the necessity of providing families with suitable money value commensurate with local necessities and capable of eliminating undesirable factors which may bring about unhealthy conditions. Based on statistics for period 1907-1912.

Standardization and Administration of Wages, H. P. Kendall and E. D. Howard. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 35-37. Consequences of system of contractual relations between employers and employees; work of the War Labor Policies Board; post-war labor problems; advisability of establishing system of organized labor participation in management.

Welfare

Welfare or Manpower Engineering? Frances A. Kellor. Nat. Efficiency Quarterly, vol. 1, no. 3, Nov. 1918, pp. 123-139. Contends that welfare work does not touch basic structure of plant management and that industrial relationship must be built in terms of engineering—impersonal, accurate, just and coördinated.

Women

Wartime Experience With Women Metal Workers. Foundry, vol. 47, no. 317, Jan. 1919, pp. 6-7. Their efficiency has been demonstrated in core shops, foundries and metal-working plants generally and in some respects they have been found superior to men.

Women Workers and Labor Turnover, Ida May Wilson. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 67-68. Temperamental and psychological factors determining complacency and permanency of women employees.

Women in Industry. Travelers Standard, vol. 6, no. 12, Dec. 1918, pp. 237-256, 9 figs. Present and future need for women; their limitations; selecting and training them; supervision and discipline; special aspects of safety problem; hours of labor; sanitation and general welfare; reference to American and European practices.

Woman's Place in Scientific Industry. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 263-264. Woman's labor after demobilization.

The Women in Our Industries. Jl. Elec., vol. 41, no. 11, Dec. 1, 1918, pp. 499-500. Record of situation in U. S. with special reference to conditions in the West.

Developing Latent Labor Forces, John E. Otterson. Nat. Efficiency Quarterly, vol. 1, no. 3, Nov. 1918, pp. 168-178. Women as laborers.

Let the Women Do the Work, D. C. Fessenden. Metal Trades, vol. 9, no. 11, Nov. 1918,

pp. 435-438, 4 figs. Experience of several western companies.

LEGAL

Boiler Making

Legal Decisions Affecting Boiler Makers, John Simpson. Boiler Maker, vol. 18, no. 12, Dec. 1918, pp. 339-340. Employer responsible for condition of tools; employers' liability in America and England; employee's risk when precaution is disregarded; decision covering steam-pipe fitting; liability under federal boiler inspection act.

Change of Appliances

Change of Appliances, Chesla C. Sherlock. Power, vol. 48, no. 25, Dec. 17, 1918, p. 887. Some legal decisions.

Engineering License Laws

Engineering License Laws. Can. Engr., vol. 35, no. 25, Dec. 19, 1918, pp. 530 and 535. Report of committee appointed by Am. Assn. Engrs. to gather information concerning state engineering license laws, either proposed or in operation, and to draw up a standard license law.

Labor Legislation

Coordination of Legislative and Operative Functions in Labor Essential to Success, Harry Tipper. Automotive Indus., vol. 39, no. 23, Dec. 5, 1918, pp. 958-959 and 986. Organization fundamentals and changes; experiments in organization and their advantages. (Second series.)

Power Plants

Some Recent Legal Decisions. Power, vol. 48, no. 27, Dec. 31, 1918, pp. 970,971. Brief reports of some cases involving power plants.

LIGHTING

Chicago Factories

Productive Intensities, Wm. A. Durgin. Trans. Illum. Eng. Soc., vol. 13, no. 8, Nov. 20, 1918, pp. 417-424, and (discussion), pp. 424-428, 6 figs. Illumination survey of Chicago factories having connected load of 100 kw. or more.

Electrical Manufacturing Plants

Improved Lighting of Electrical Manufacturing Plants, F. H. Bernhard. Elec. Rev., vol. 73, no. 24, Dec. 14, 1918, pp. 917-922, 7 figs. Last of series of twelve articles on electric lighting in industries.

Inspection

Light, Electricity and the Shop, C. E. Clewell. Am. Mach., vol. 49, no. 25, Dec. 19, 1918, pp. 1117-1122, 11 figs. Description of educational plan for state factory inspectors in New Jersey and Pennsylvania and some results accomplished in these states.

Machine Tools

The Lighting of Machine Tools, Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 276-279, 4 figs. Schemes for lighting punching machine, bench vises, turret lathe and drilling machine.

War Effects

Lighting Units for Commercial, Office and Home Illumination. Elec. Rec., vol. 24, no. 6, Dec. 1918, pp. 45-53, 37 figs. Discussion of present practice with illustrations of the various types; emphasis laid on effect of war.

Wartime Lighting Economies. Trans. Illum. Eng. Soc., vol. 13, no. 8, Nov. 20, 1918, pp. 387-400 and (discussion) pp. 400-410. Rules limiting use of artificial light to minimum necessary numbers of hours per day, and promoting efficient use of artificial light during those hours. Prepared by Committee on War Service of Illum. Eng. Soc.

See also MARINE ENGINEERING, Yards (Illumination).

PUBLIC REGULATION

Federal Control of Labor

Effect of Federal Control on Railway Labor, W. S. Carter. Ry. Age, vol. 65, no. 24, Dec. 13, 1918, pp. 1061-1064. Outline of efforts to create improved relations between employer and employee.

Water-Power Development

A Plan for Power Development, C. Edward Magnusson. Jl. Elec., vol. 41, no. 10, Nov. 15, 1918, pp. 549-460, 1 fig. Scheme permitting Government aid without doing away with private enterprise and its application to State of Washington.

RECONSTRUCTION

Automobile Industry

Some Probable Effects of the War on the Automobile Industry, A. A. Remington. Automobile Engr., vol. 8, no. 120, Nov. 1918, pp. 306-311, 2 figs. Presidential address before Instn. Automobile Engrs.

British Export Trade

Quantity or Quality, W. Slater. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 284-286. Remarks on British export trade.

Canada

Reconstruction in Canada and the Social and Economic Forces Which Will Condition It, J. A. Stevenson. Survey, vol. 41, no. 14, Jan. 4, 1919, pp. 441-446. Problem of repatriation of troops as being worked out by committee of cabinet.

Canada Readjusting from War to Peace, Carroll E. Williams. Mfrs. Rec., vol. 75, no. 1, Jan. 2, 1919, pp. 159-160. Plans of industrial and agricultural work for returning soldiers.

Dumping

The Truth About German Steel Dumping, E. T. Good. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 286-288. Warning against introduction into England of German products; former German policy.

Exports

World Markets for American Manufacturers, Lynn W. Meekins. Sci. Am., vol. 120, no. 1, Jan. 4, 1919, p. 12. Factors limiting market in France; how Germany obtained East Indian business; possibilities in Dutch East Indies.

Cultivating Japanese Automotive Field (V), Tom O. Jones. Automotive Indus., vol. 39, no. 25, Dec. 19, 1918, pp. 1059-1061. Opportunities for American tire makers; suggestions to American manufacturers.

Cultivating the Chinese Automotive Field, Tom O. Jones. Automotive Indus., vol. 39, no. 26, Dec. 26, 1918, pp. 1106-1107 and 1122, 5 figs. Condition of Chinese roads as a factor in automotive development; types of cars for China.

Latin-American Exports

Entering the Export Markets of Latin America. IV The Value of Insurance, Percy F. Martin. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 280-283. Advisability of insuring shipments against loss or damage.

Post-War Trade

Obstacles to Post-War Trade, Richard Cooper. Soc. of Engrs. Jl. & Trans., vol. 9, no. 11, Nov. 1918, pp. 169-179 and (discussion) pp. 179-187. Sets forth problems of reorganization of industry to peace work. Possible profit from a system of high wages indicated from author's experience in engineering and chemical industry.

Readjustment Problems

Readjustment Problems Confronting America, Harry A. Wheeler. Gas Age, vol. 42, no. 12, Dec. 16, 1918, pp. 511-514. Presidential address before Chamber of Commerce of United States, Atlantic City. Also in Am. Fertilizer, vol. 49, no. 12, Dec. 7, 1918, pp. 38-39.

Reconstruction Problems, M. F. Chase. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. IX-XI. Parallel between European and American reconstruction problems; cancellation of contracts for war materials.

Petroleum and Reconstruction Problems, Chester Naramore. Bul. Am. Inst. Min. Engrs., no. 145, Jan. 1919, pp. XIV-XVIII. Erroneousness of conception that petroleum demands will decrease after signing of peace. Present leading position of U. S. in industry and means to perpetuate it.

Reconstruction of American Business, Edwin L. Seabrook. Boiler Maker, vol. 18, no. 12, Dec. 1918, pp. 338 and 352. Advisability of Government control during transitional period; adjustment of wages and prices; special legislation.

Organizing the Nation for Peace, L. W. Alwyn-Schmidt. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 45-48. Survey of general plans of England, France and Germany for redistributing labor, repatriating army, invalid labor, reëstablishing artisans and industrial housing. Also points out difficulties to be faced by United States in meeting world-wide competition.

See also MECHANICAL ENGINEERING, Motor Car Engineering (Exports).

SAFETY ENGINEERING

California State Commission

Accident Prevention, John R. Brownell. Proc. Pacific Ry. Club, vol. 2, no. 8, Nov. 1918, pp. 12-13. Work being done by commission which administers State Compensation Fund created by California legislature in Workmen's Compensation Insurance and Safety Act.

Causes of Industrial Accidents

Factors Concerned in the Causation of Industrial Accidents. Automotive Indus., vol. 39, no. 22, Nov. 28, 1918, pp. 916-918. Comparison of report of Health of Munition Workers Committee of British Ministry of Munitions with U. S. Labor Bureau statistics.

Reduction of Accident Hazard, R. L. Gould. Cassier's Eng. Monthly, vol. 54, no. 5, Nov. 1918, pp. 265-270, 1 fig. Discussion of questions confronting safety engineer in his endeavor to minimize risk of accident to limb and life in industrial plants and suggestions for promoting work.

Cranes

Safety First for Crane and Operator. Jl. Elec., vol. 41, no. 11, Dec. 1, 1918, pp. 524-525, 2 figs. Special protection panel for cranes having three polyphase motors. Panel provides two inverse time-element overload relays for each motor.

Diseases

Diseases and Infections, Chesla C. Sherlock. Am. Mach., vol. 50, no. 1, Jan. 2, 1919, pp. 18-30. Some legal interpretations of liability.

Dust Inhalation

Effects of Dust Inhalation, J. S. Haldane. Queensland Government Min. Jl., vol. 19, no. 222, Nov. 15, 1918, pp. 515-517. Analysis of dust and result of experiments on its reported destructive effects. Paper submitted to Chem. Metallurgical & Min. Soc. of South Africa and to Instn. Min. Engrs.

Eye Protection

Eye Protection in Iron Welding Operations, W. S. Andrews. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 961-966, 7 figs. Charts illustrating spectra of commercially available glasses and their combinations, for use in selecting best protection against radiations of welding arc.

Inflammable Materials

The Dangers of Explosion With Inflammable Liquids and Vapors, W. Payman. Sci. Am. Supp., vol. 87, no. 2244, Jan. 4, 1919, p. 7. Criteria for judging liability of a given liquid to produce dangerous conditions; precautions necessary in handling inflammable liquids. From Jl. Soc. Chem. Indus.

The Dangers of Explosion with Inflammable Liquids and Vapors, W. Payman. Jl. Soc. Chem. Indus., vol. 37, no. 21, Nov. 15, 1918, pp. 406R-408R. Limits of inflammability of commoner organic solvents as recorded by different observers.

Lighting Defects

The Relation Between Light Curtailment and Accidents, R. E. Simpson. Trans. Illum. Eng. Soc., vol. 13, no. 8, Nov. 20, 1918, pp. 429-435 and (discussion) pp. 435-438. Considerations based on statistical figures and present systems of factory illumination.

Metal Industries

Causes and Prevention of Accidents in the Metal Industries, L. W. Chaney and Hugh S. Hanna. Metal Trades, vol. 9, no. 12, Dec. 1918, pp. 498-499, 3 figs. From Bul. 234 of U. S. Department of Labor.

Quarries

Accident Prevention in Quarry Operation, William H. Baker. Cement & Eng. News, vol. 30, no. 12, Dec. 1918, pp. 27-28. Work of Committee on Safety and Welfare of Atlas Portland Cement Co. From address before Nat. Safety Council.

Shop Safety Organization

Shop Safety Organization. The Bulletin, N. Y. State Indus. Commission, vol. 4, no. 3, Dec. 1918, pp. 48-52 and 57. Plan worked out by Bureau of Statistics and Information of State Industrial Commission and discussed at session of Industrial Safety Congress.

Steel Industry

Hazards Reduced in Steel Industry. Iron Trade Rev., vol. 63, no. 24, Dec. 12, 1918, pp. 1341-1345, 5 figs. Review of safety work of iron and steel industry in the last few years. From Bul. 234 of U. S. Bureau of Labor Statistics.

See also MINING ENGINEERING, Mines and Mining (Fire Protection; Safety).

SALVAGE

Waste Reduction

Conservation of Materials in Our Plants, Francis G. Hall. Am. Drop Forger, vol. 4, no. 11, Nov. 1918, pp. 440-441. Reducing waste by careful handling. (Second of Series.)

Salvaging Miscellaneous Wastes, W. Rockwood Conover. Indus. Management, vol. 57, no. 1, Jan. 1919, pp. 12-16, 3 figs. Methods for salvaging rubber, leather, fiber, rope, string, muslin rags, cloth trimmings, burlap sacks, old belting, asbestos sheeting, mica, insulation papers, wire, waste paper, boxes,

barrels, cans, containers, emery cloth, cotton waste, brooms, brushes, oil and fuel gas.

See also MECHANICAL ENGINEERING, Foundries (Salvage Work).

TRANSPORTATION

Inland Waterways

Handling Freight on Inland Waterways, H. McL. Harding. Int. Mar. Eng., vol. 23, no. 12, Dec. 1918, pp. 667-670, 6 figs. Advantages of effective inland terminals; operating costs small; importance of mechanical methods.

Motor-Truck Transport

Cost and Charges of Motor Truck Service. Ry. Rev., vol. 63, no. 23, Dec. 7, 1918, pp. 805-810, 9 figs. Some motor truck cost figures.

Rural Motor Express, S. W. Fenn. Jl. Soc. Automotive Engrs., vol. 3, no. 6, Dec. 1918, pp. 383-384 and (discussion) pp. 384-388. Work accomplished in Iowa; moving crops by motor trucks in Idaho; organization of rural lines in Tennessee, Alabama and Georgia.

VARIA

City Manager

Progress, Prospects and Pitfalls of the New Profession of City Manager, O. E. Carr. Can. Engr., vol. 35, no. 24, Dec. 12, 1918, pp. 513-514 and 519. Abstracted from paper before Fifth Annual City Mgrs. Convention.

Industrial Technology

Alcohol

Industrial Alcohol. Times Eng. Supp., no. 529, Nov. 1918, p. 228. Possible sources of supply.

Ammonium Nitrate

Coke Makers Now Make Nitrate of Ammonia, Mark Meredith. Chem. Engr., vol. 26, no. 12, Nov. 1918, pp. 451-452. English research proves it is commercially possible to turn ammonia by-product of coke ovens into nitrate of ammonia.

Clays

The Nature of the Air Content of Pugged Clays, H. Spurrier. Jl. Am. Ceramic Soc., vol. 1, no. 8, Aug. 1918, pp. 584-585, 1 fig. Apparatus to secure gas occluded in clay and result of analysis of gases collected from pugged-clay samples.

Burning Clay Wares (XXXII), Ellis Lovejoy. Clay-Worker., vol. 70, no. 6, Dec. 1918, pp. 496-498, 12 figs. Principle and arrangement of single outside stack kilns.

Chemical Industry

The Synthetic Organic Chemical Industry, Francis H. Carr. Jl. Soc. Chem. Indus., vol. 37, no. 22, Nov. 30, 1918, pp. 425R-428R. Importance of chemistry to the life of a nation and achievements of British chemists during years of war. From chairman's address to Nottingham Section.

Recent Progress and Future Development of Chemical Industries in France (Les progrès récentes et l'avenir des industries chimiques en France), Paul Razous. Génie Civil, vol. 73, nos. 19, 20 and 21, Nov. 9, 19 and 23, 1918, pp. 368-371, 390-393 and 407-410. Nov. 19: Potassium and sodium bichromates; mineral colors and varnishes; electrochemical industries; oils, pastes; fermentation; sugars; Nov. 23: Tanning industry; resins distillation of tars; carbonization of wood; artificial coloring.

The Criteria in the Declaration of Chemical Independence in the United States, I. Newton Kugelmass. Science, vol. 48, no. 1251, Dec. 20, 1918, pp. 608-612. Address at meeting of Alabama Section, Am. Chem. Soc.

Coal Products

Utilization of Lignite. Water & Gas Rev., vol. 29, no. 6, Dec. 1918, pp. 13-14. Characteristics of gas, ammonia, oils and tar obtained as by-products from lignite.

Distillation Tar from Mond Gas Plant, A. Gatley Lyons. Chem. Eng. & Min. Rev., vol. 10, no. 121, Oct. 5, 1918, pp. 19-20, 1 fig. Description of installation at Sulphide Corporation Works, New South Wales. Paper before Aust. Inst. Min. Engrs.

The Manufacture of Retort Coal-Gas in the Central States Using Low-Sulphur Coal from Illinois, Indiana and Western Kentucky, W. A. Dunkley and W. W. Odell. State of Ill., Div. Geol. Survey, bul. 21, 24 pp., 3 figs. Present use of central district coals; problems in their use in coal-gas manufacture; results reported; economical advantage of using them.

Dust Precipitation

Removing Foundry Dust by Electric Precipitation, H. D. Egbert. Foundry, vol. 47, no. 317, Jan. 1919, pp. 43-45, 6 figs. Two sets of electrodes used in Cottrell process, dust being charged with static electricity and attracted to collecting electrodes.

Cleaning Blast Furnace Gases by Electrical Precipitation, N. H. Gellert. Mfrs. Rec., vol. 74, no. 24, Dec. 12, 1918, p. 58. Tests on furnace operating on spiegeleisen and having a rated capacity of 200 tons of pig iron per day.

Enamels

Antimony Oxide as an Opacifier in Cast-Iron Enamels, J. B. Shaw. Jl. Am. Ceramic Soc., vol. 1, no. 7, July 1918, pp. 502-511 and (discussion) pp. 511-513. Results of experimental efforts to outline satisfactory working formulæ having antimony oxide as chief opacifying agent.

Preparation and Application of Enamels for Cast Iron, Homer F. Staley. Jl. Am. Ceramic Soc., vol. 1, no. 8, Aug. 1918, pp. 534-555, 3 figs. Details and arrangement of machinery in storing, weighing and mixing raw materials, melting enamel, drying, grinding and screening; operations followed in enameling process; enameling-room equipment.

How High-Grade Enameling Is Done, E. C. Kreutzberg. Iron Trade Rev., vol. 63, no. 23, Dec. 5, 1918, pp. 1290-1291, 4 figs. Practice followed in a New York plant.

Filtration

Filtration in the Laboratory, Robt. T. Smith. Color Trade Jl., vol. 4, no. 1, Jan. 1919, pp. 21-24. Modern methods: natural suction and under hydraulic head. Suggestions in regard to selection of papers and adaptation of accessory apparatus.

Glass

The Effect of Certain Impurities in Causing Milkiness in Optical Glass, C. N. Fenner and J. B. Ferguson. Jl. Am. Ceramic Soc., vol. 1, no. 7, July 1918, pp. 468-476. Reasons for opalescence with which certain pots of glass were affected at Bausch and Lomb plant and how it was overcome.

Gypsum

Some Factors Influencing the Time of Set of Calcined Gypsum, F. F. Householder. Jl. Am. Ceramic Soc., vol. 1, no. 8, Aug. 1918, pp. 578-583, 5 figs. Tests to determine effect of varying consistency of mixtures, time and rate of stirring and temperature of water used in mixing.

Mantle Lamps

Influence of B.t.u. on Gas Mantle Efficiency, R. S. McBride, W. A. Dunkley, E. C. Crittenden and A. H. Taylor. Gas Age, vol. 42, no. 12, Dec. 16, 1918, pp. 519-521, 3 figs. Extract from technological paper 110 of U. S. Bureau of Standards upon tests made in 1916 and giving data upon operation of mantle lamps.

Photography

Dyes in Photography, A. Seyewetz. Sci. Am. Supp., vol. 87, no. 2244, Jan. 4, 1919, p. 6. Their use in orthochromatic work and for non-halation plates. Abstract of paper in Chemie et Industrie, published in the British Jl. of Photography.

Pickling

The Chemistry of Pickling Baths. Automotive Indus., vol. 39, no. 23, Dec. 5, 1918, pp. 960-961. Action of acid on metal below scale; effect of variations in strength of bath and in temperature; modifying action of bath by organic and inorganic materials.

Niter Cake Substitute for Pickling Steel, E. E. Corbeit. Blast Furnace, vol. 6, no. 12, Dec. 1918, pp. 497-501. Investigation conducted by U. S. Bureau of Mines chiefly for purpose of conserving sulphuric acid.

Picric Acid

The Manufacture of Picric Acid, Alexander Murray. Color Trade Jl., vol. 4, no. 1, Jan. 1919, pp. 5-8, 2 figs. General features of nitrating pots; nitrating operation; description of large installation; crystallization of picric acid.

Silica Products

Study of Silica Products, A. Bigot. Iron & Coal Trades Rev., vol. 47, no. 2645, Nov. 8, 1918, pp. 521-522. Recommendations in regard to grinding rocks and burning products. Abstract of paper before Refractories Section of Ceramic Soc. of Swansea.

Sugar Industry

On the Manufacture of Polariscopes in the United States, C. A. Browne. Louisiana Planter, vol. 62, no. 1, Jan. 4, 1919, pp. 12-14. Reasons for and against proposed change in manufacture of saccharimeters and getting away from German sugar scale and starting anew upon international scale proposed by Sidersky and Pellet. Opinions from 14 leading American chemists quoted.

Ultra-Violet Light

Ultra Violet Light (XIX), Carleton Ellis and A. A. Wells. Chem. Engr., vol. 26, no. 12, Nov. 1918, pp. 463-464 and 473. Its application in chemical arts.

Vegetable Drying

The Desiccation of Vegetable Substances at Different Temperatures (Sur la dessiccation des substances végétables effectuée à différentes temperatures), G. Andre. Bulletin de la Société Chimique de France, vol. 23, no. 10, Oct. 1918, pp. 430-437. Results of experiments at temperatures above 100 deg. cent. in which the substances were subjected to dry air deprived of CO_2.

Yttrium

The Preparation and Properties of Yttrium Mixed Metal, J. F. G. Hicks. Jl. Am. Chem. Soc., vol. 40, no. 11, Nov. 1918, pp. 1619-1626, 1 fig. Preparation in powder form by decomposing anhydrous chlorides with sodium in vacuo and by electrolysis of these chlorides in fused condition; study of solution of yttrium earth metals in fused cryolite and of loss of yttrium chloride by volatilization.

Water Gas

Water-Gas Manufacture with Central District Bituminous Coals as Generator Fuel, W. W. Odell and W. A. Dunkley. State of Ill., Div. Geol. Survey, bul. 22, 24 pp., 3 figs. Data gathered by writers during inspection of 20 water-gas plants in Illinois and surrounding states, in which bituminous coal from central mining district of Illinois, Indiana and western Kentucky is being used as generator fuel.

Wood Waste

Some Uses of Wood Waste, Armin Elmendorf. Wis. Engr., vol. 23, no. 2, Nov. 1908, pp. 33-39, 2 figs. Methods for converting waste material into products valuable for use in industries.

See also ELECTRICAL ENGINEERING, Power Applications (Electrochemical Processes).

Railroad Engineering

ELECTRIC RAILWAYS

Argentina

Electric Traction on the Central Argentine Railway. Ry. Gaz., vol. 29, no. 20, Nov. 15, 1918, pp. 518-524, 8 figs. Rolling stock. (Continuation of serial.)

Regenerative Braking

Braking System Permitting Recovery of Energy in Vehicles Operated by Single-Phase Commutator Motors (Système de freinage avec récupération d'énergie pour véhicles actionnés par moteurs monophasés à collecteur), Behn-Eschenburg. Génie Civil, vol. 75, no. 18, Nov. 2, 1918, pp. 347-350, 5 figs. Theoretical aspect of question as suggested from new developments permitting recovery of braking energy at all speeds and with any charge.

Rolling Stock

The New Rolling Material of the Dutch Electric Railways Co. (Het nieuwe rollend materieel der E. S. M.), H. F. Adams. De Ingenieur, year 33, no. 46, Nov. 16, 1918, pp. 893-904, 13 figs. Description of new electric cars.

ELECTRIFICATION

California

Railway Electrification Recommended. Jl. Elec., vol. 41, no. 10, Nov. 15, 1918, pp. 465-466. Report of investigations made preliminary to recommending electrification of mountain divisions of Cal. railroads to Director General of Railroads.

Montreal Tunnel

Electrification of the Montreal Tunnel Zone, William G. Gordon. Proc. Am. Inst. Elec. Engrs., vol. 37, no. 12, Dec. 1918, pp. 1285-1296, 7 figs. Method of constructing tunnel 3.1 miles long; details of equipment of substation and dimensions of locomotives and motor cars; features of catenary system due to local conditions and prevailing extremely low temperatures. Also Elec. News, vol. 27, no. 23, Dec. 1, 1918, pp. 29-30.

LABOR

Women

Women in the Service of the Railways, Pauline Goldmark. Ry. Age, vol. 65, no. 23, Dec. 6, 1918, pp. 1016-1018. Address before Labor

Reconstruction Conference, Academy of Political Science, New York, Dec. 6, 1918.

LOCOMOTIVES

Boilers

Report of Inspection of Locomotive Boilers. Ry. Rev., vol. 63, no. 26, Dec. 28, 1918, pp. 907-909, 1 fig. Department of Locomotive Inspection shows favorable results notwithstanding handicap of war.

Design

Modern Locomotive Engine Design and Construction (XLIII). Ry. Engr., vol. 39, no. 467, Dec. 1918, pp. 222-227, 4 figs. Different types of superheaters for any desired working pressure; design calculations and formulæ.

Feedwater Heating

Locomotive Feed Water Heating, H. S. Vincent. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, pp. 645-649, 8 figs. Discussion of exhaust steam and waste-gas methods of preheating for locomotive boilers.

Fireboxes

Radiant Heat and Firebox Design, J. T. Anthony. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, pp. 658-660, 3 figs. Combustion chambers increase furnace efficiency and radiation; long tubes are of little value. From paper before Central Railway Club, May, 1918.

Individual Types

4-6-0 Passenger Engine and Double Bogie Tender: London and South-Western Railway. Ry. Engr., vol. 39, no. 467, Dec. 1918, pp. 228-229 and insert, 3 figs. Working drawings of engine and tender built at Eastleigh. Supplement to illustrations and particulars given in Oct. issue, pp. 184-186.

2-10-2 Type Locomotive for the Rock Island Lines. Ry. Age, vol. 65, no. 23, Dec. 6, 1918, pp. 992-994, 5 figs. Description with drawings and principal data.

A. T. & S. F. 4-8-2 Type Locomotives. Ry. Mech. Engr., vol. 92, no. 12, Dec. 1918, pp. 649-652, 2 figs. Drawings, description and principal data.

Standard Locomotives

Standard 4-8-2 and Light 2-10-2 Locomotives. Ry. Age, vol. 65, no. 24, Dec. 13, 1918, pp. 1067-1073, 12 figs. Drawings, descriptions and principal data.

Stokers

Mechanical Stoking of Locomotives, W. S. Bartholomew. Southern & Southwestern Ry. Club, vol. 14, no. 11, Sept. 1918, pp. 40-70 and (discussion) pp. 71-76, 62 figs. General arrangement of various types of stokers and their application to large freight and passenger locomotives; development of duplex stoker; result obtained in different types of locomotives.

Superheaters

Locomotive Superheater Maintenance. Ry. Mech. Eng., vol. 92, no. 11, Nov. 1918, pp. 621-623, 5 figs. From Bulletin No. 4, Locomotive Superheater Company.

Superheater Locomotive Performance. Ry. Mech. Eng., vol. 92, no. 12, Dec. 1918, pp. 652-655, 1 fig. From committee report presented at 1918 convention of Traveling Engrs'. Assn.

Three-Cylinder Locomotives

Three-Cylinder Locomotives, H. Holcroft. Ry. News, vol. 110, no. 2862, Nov. 9, 1918, pp. 331-332. Outline of British practice and study of problems involved in operating three valves by means of two gears. Paper before Instn. Locomotive Engrs.

Tires

Falling Weight Test on Railway Tyres, J. H. G. Monypenny. Engineering, vol. 106, no. 2759, Nov. 15, 1918, pp. 545-547, 8 figs. General discussion of this method of testing; suggestions in regard to changes in method.

NEW CONSTRUCTION

Hetch-Hetchy Project

San Francisco's Venture in Railroad Construction, A. J. Cleary. Ry. Age, vol. 65, no. 24, Dec. 13, 1918, pp. 1047-1050, 8 figs. Account of completion of 68-mile line as facility for Hetch Hetchy project.

OPERATION AND MANAGEMENT

British

British Railways Under War Conditions. Engineer, vol. 126, no. 3281, Nov. 15, 1918, pp. 410-412. Early events after outbreak of hostilities. (Ninth article.)

British Railway Engineering and Operation—Some Immediate Problems to Be Faced, John A. F. Aspinall. Ry. News, vol. 110, no. 2862, Nov. 9, 1918, pp. 326-330. Presidential address before Instn. Civil Engrs.

Foreman

Mission of Railway General Foreman, Robert Quayle. Ry. Jl., vol. 25, no. 1, Jan. 1919, pp. 28-29. Possible ways in which foremen can approach their men and develop in them loyalty to organization.

Fuel Conservation

Cooperation in Fuel Conservation, D. R. MacBrain. Official Proc. N. Y. R. R. Club, vol. 29, no. 1, Dec. 1918, pp. 5447-5452. Necessity to secure interest in fuel conservation of every one in a railroad operating organization; influence of general condition of locomotive on fuel economy; time and experience required by an engineer to become master of locomotive engineering; education of firemen.

The Responsibility of General Officers for Fuel Economy, R. J. Pearson. Official Proc. N. Y. R. R. Club, vol. 29, no. 1, Dec. 1918, pp. 5445-5447. Importance of establishing system of supervision which will enable officers to ascertain consumption of fuel.

Address of Mr. Eugene McAuliffe. Official Proc. N. Y. R. R. Club, vol. 29, no. 1, Dec. 1918, pp. 5437-5445. Railway fuel, and railway fuel conservation. Working details of Fuel Conservation Section.

Reclamation

Reclamation on Chicago, Milwaukee & St. Paul. Ry. Rev., vol. 63, no. 26, Dec. 28, 1918, pp. 903-905. Adapted from report of special committee (H. S. Sackett, chairman) investigating status of reclamation with view to formation of future policy.

Tonnage Rating

Train Resistance and Tonnage Rating. Ry. Jl., vol. 25, no. 1, Jan. 1919, pp. 29-31. Reports received by Committee of Master Mechanics' Convention from 25 roads, dealing with experience, tests conducted, regulations adopted and methods of supervision.

PERMANENT WAY AND BUILDINGS

Ballasting

Modern Track Needs Good Ballast, R. C. Cram. Elec. Ry. Jl., vol. 52, no. 25, Dec. 21, 1918, pp. 1080-1085, 14 figs. Why well-ballasted track is economical to maintain; types of construction; properties and materials necessary for ideal ballast; ballast and ballasting from standpoint of best engineering practice.

Concrete-Base Track

Concrete Base Track Gives Good Results on Northern Pacific Railway. Eng. News-Rec., vol. 81, no. 24, Dec. 12, 1918, pp. 1071-1074, 13 figs. New type of construction four years in actual service; concrete slabs built on gravel roadbed have wood supports for rails; no ballast used; maintenance work not continuous but intermittent.

Grade Crossings

The Proper Engineering Treatment of Necessary Railroad Grade Crossings, Rodman Wiley. Good Roads, vol. 16, no. 26, Dec. 21, 1918, pp. 241-243. Claims no engineering advice has dictated present policy of establishing crossings in railroads. Paper before Am. Assn. of State Highway Officials, Chicago.

Stresses in Track

Stresses in Permanent Way. Ry. Engr., vol. 39, nos. 464, 465 and 466, Sept., Oct. and Nov. 1918, pp. 179-181, 191-194 and 211-213, 13 figs. Report of joint committee of Am. Soc. Civil Engrs. and Am. Ry. Eng. Assn., appointed to investigate stresses in railway track.

Ties

A New Concrete Railroad Tie. Mun. & County Eng., vol. 55, no. 6, Dec. 1918, pp. 212-213, 3 figs. Details of tie satisfactorily used for several years on municipal railroad of San Francisco, Cal.

Service Tests of Cross-Tie, P. R. Hicks. Bul. Am. Ry. Eng. Assn., vol. 20, no. 210, Oct. 1918, pp. 21-71. Tables comprising 350 service test records on 28 different species of ties, including 30 completed records submitted by 22 railroads.

Resilient Chairs and Reinforced Concrete Ties for Railway Track. Contract Rec., vol. 32, no. 47, Nov. 20, 1918, pp. 921-922, 2 figs. Details of sleeper said to have given satisfactory service on East Indian Ry.

Track Improvement

Making the Old Track Last a Little Longer, P. Ney Wilson. Elec. Ry. Jl., vol. 52, no. 24, Dec. 14, 1918, pp. 1053-1054, 5 figs. What Connecticut Co. did to extend life of stretch of track in New Haven, with particular reference to arc welding.

See also CIVIL ENGINEERING, *Bridges (Railway Bridges).*

RAILS

Transverse Fissures

Transverse Fissures Cause Rail Failures, Ry. Age, vol. 65, no. 23, Dec. 6, 1918, pp. 1007-1009. Suggests that rails are being stressed beyond service limit. (From report by W. P. Borland, chief of Bureau of Safety of Interstate Commerce Commission of an investigation made by James E. Howard, engineer-physicist of Commission.) Also Ry. Rev., vol. 63, no. 24, Dec. 14, 1918, pp. 843-847, 11 figs.

Reheating as Cure for Rail Fissure, G. F. Comstock. Iron Trade Rev., vol. 63, no. 26, Dec. 26, 1918, pp. 1457-1462, 17 figs. Metallographic investigations of transverse fissures, using a special etching reagent; results apparently support theory that transverse failures are due to defect in steel and that reheating of blooms will diffuse bands of phosphorus. From paper to be presented at Feb. meeting of Am. Inst. Min. Engrs.

ROLLING STOCK

Cleaning

Rotary Brushes for Cleaning Cars, C. H. Shaffer. Ry. Jl., vol. 25, no. 1, Jan. 1919, pp. 26-27, 2 figs. Brush operated at about 900 r.p.m. through special flexible shaft used in conjunction with air drill.

Refrigerator Car, Standard

Government Standard Refrigerator Car. Ry. Rev., vol. 63, no. 25, Dec. 21, 1918, pp. 865-868, 5 figs. Data and further description of Government's new design. Detail drawings. Also Ry. Mech. Eng., vol. 92, no. 12, Dec. 1918, pp. 663-668, 6 figs, and Ry. Age, vol. 65, no. 25, Dec. 20, 1918, pp. 1115-1117.

Welded Freight Car

Electrically Welded Gondola Car. Ry. Rev., vol. 63, no. 24, Dec. 14, 1918, pp. 833-835, 5 figs. Car constructed for C., B. & Q. R. R. pioneer attempt at fabricating steel freight-car structure by process of electric welding. Also Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 913-915, 8 figs.

SAFETY AND SIGNALING SYSTEMS

Accident Prevention

The Conservation of Man-Power, H. A. Adams. Proc. Pacific Ry. Club, vol. 2, no. 8, Nov. 1918, pp. 7-11. Brief record of work done by Government, Congress and private agencies to prevent accidents in railroad operation, including present endeavors of U. S. Railroad Administration.

SHOPS

A. E. F. Repair Shops

Railroad Repair Shops in France Equipped and Operated by American Forces, Robert K. Tomlin, Jr. Eng. News-Rec., vol. 81, no. 26, Dec. 26, 1918, pp. 1178-1182, 6 figs. Features of shops; individual electric drive for all machine tools.

Roundhouse Design

Locomotive Round-House at San Bernardo, Chile (La maestranza de San Bernardo, Chile), C. V. Cruchaga. Boletin de la Sociedad de Fomento Fabril, year 35, no. 9, Sept. 1918, pp. 609-614. Details of American design built of concrete and is said to be largest of its kind in the world.

Roundhouse Methods

Mileage of Engines—Its Relation to Cost of Shop and Running Repairs, George H. Logan. Ry. Jl., vol. 25, no. 1, Jan. 1919, pp. 24-26. Remarks on shop practice based on experiences in roundhouses.

Accuracy in Locomotive Repairs, M. H. Williams. Ry. Mech. Eng., vol. 92, no. 12, Dec. 1918, pp. 673-677, 8 figs. Methods of making and of fitting new and repair parts for locomotives with gages and micrometers.

Tools, Brass-Working

Brass-Working Tools in a Railroad Shop, Frank A. Stanley. Am. Mach., vol. 49, no. 23, Dec. 12, 1918, pp. 1081-1084, 8 figs. Describes tools for making blow-off valves and their fittings.

Welding

Arc Welding in Railroad Shops, B. C. Tracy. Gen. Elec. Rev., vol. 21, no. 12, Dec. 1918, pp. 887-898, 20 figs. Based on its success in locomotive repair work, writer believes arc welding must be given serious consideration by railroads, not only from an economic viewpoint, but also to increase transportation facilities.

TERMINALS

South Boston

New Haven Improvements at South Boston Terminal. Ry. Age, vol. 65, no. 26, Dec. 27, 1918, pp. 1149-1152, 7 figs. Involve construction of two additional tracks and depressing old line. All done under heavy traffic.

Munitions and Military Engineering

Ambulance Trains

Ambulance Train of the American Army (Train-ambulance de l'armée américaine). Génie Civil, vol. 73, no. 18, Nov. 2, 1918, pp. 341-343, 15 figs. Disposition and arrangement of coaches (built in England) for transportation of wounded soldiers.

Automobile Transport

Organization of the French Army Automobile Service, W. F. Bradley. Automotive Indus., vol. 39, no. 26, Dec. 26, 1918, pp. 1093-1095. How repairs were handled. Equipment included 90,000 trucks and 150,000 men.

Military Transport Chassis. Part IX. Automobile Engr., vol. 8, no. 121, Dec. 1918, pp. 346-349, 4 figs. Their performance under war conditions. Details of Pierce-Arrow 5-ton model R. S truck.

Camp Holabird—Largest Truck Overhaul Depot. Automotive Indus., vol. 39, no. 25, Dec. 19, 1918, pp. 1053-1055, 8 figs. Data on plant with capacity for assembling 30 trucks a day and crating 22 an hour for shipment.

Construction Work

How Construction Met the Issue, R. C. Marshall. Am. Contractor, vol. 39, no. 51, Dec. 21, 1918, pp. 22-25. Accomplishments of construction Division of War Department. Functions, organizations and procedure; "cost-plus and sliding scale fee contract." Address at meeting of Gen. Contractors' Assn.

Gun Erosion

Experts Discuss Big Gun Erosion, Hudson Maxim. Iron Trade Rev., vol. 63, no. 26, Dec. 26, 1918, pp. 1463-1464. Analysis of causes producing erosion and study of possibilities to overcome them, together with recommendations in regard to material and method of lining. Discussion of Henry M. Howe's paper before Am. Inst. Min. Engrs.

Hand Grenades

Making the American Hand Grenade, Edward K. Hammond. Machy., vol. 25, no. 5, Jan. 1919, pp. 448-453, 15 figs. First of two articles on methods of machining and loading bodies and assembling bouchons.

H. E. Shells

Manufacture of High Explosive Shells and Detonators, from the Metallurgist's View Point, C. B. Swander. Proc. Steel Treating Research Soc., vol. 1, no. 11, pp. 9-14, 5 figs. Outline of forging operations on an 8-in. American carbon-steel high-explosive shell; machining; nosing operation; heat treating; copper banding; placing detonator; British, French and Russian detonators.

Howitzers

How the 155-Mm. Howitzer Is Made, J. V. Hunter. Am. Mach., vol. 49, no. 25, Dec. 19, 1918, pp. 1123-1129, 28 figs. Third article.

Illuminating Shells

Rockets and Illuminating Shells as Used in the Present War, A. Bergman. Illum. Engr., vol. 11, no. 8, Aug. 1918, pp. 189-191. Composition and data on candlepower developed. From paper before Illum. Eng. Soc.

Military Roads

Some Phases of Military Road Work, Gordon F. Daggett. Wis. Engr., vol. 23, no. 3, Dec. 1918, pp. 79-88. Trend of construction during last two years. Difficulties encountered, organizations required and materials available in work undertaken at the front. Requirements of wearing surface for military purposes.

Railway Artillery

Railway Artillery, James B. Dillard. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 44-49, 5 figs. Development of models; types of cannon used; problems of design; barbette mortar carriages; foreign types; American types; auxiliary cars; tactical uses; value and economy of seacoast defence.

Long-Range Heavy Navy Guns with Railway Mount, D. C. Buell. Jl. Am. Soc. Mech. Engrs., vol. 41, no. 1, Jan. 1919, pp. 25-27, 5 figs. Work done in completing mobile battery of naval 14 in. 50-caliber guns originally built for use in battle cruisers.

The War Department Railway Artillery. Ry. Age, vol. 65, no. 25, Dec. 20, 1918, pp. 1113-1114, 5 figs. Brief description of 8-in., 12-in. and 14-in. railway mounts.

Semi-Steel Shells

How Semisteel Shell Are Machined. Iron Trade Rev., vol. 63, no. 22, Nov. 28, 1918, pp. 1236-1237, 17 figs. From circular of Ordnance Department recommending standard practice for manufacture of this class of projectile.

Tanks

The Mark VIII Land Cruiser, J. Edward Schipper. Automotive Indus., vol. 40, no. 1, Jan. 2, 1919, pp. 6-9, 11 figs. Technical description of large-sized battle tank developed during latter period of war; equipped with an adaptation of Liberty aircraft engine and weighs 40 tons. Also Motor Age, vol. 35, no. 1, Jan. 2, 1919, pp. 18-21, 9 figs. Mechanical features of huge model that carries 11 men.

Tools for Shell Manufacture

Special Tools and Appliances for Shell Manufacture, George A. Neubauer and Erik Oberg. Machy., vol. 25, no. 5, Jan. 1919, pp. 416-421, 7 figs. Describes number of devices used by Buffalo Pitts Co. in making 4.7 high-explosive shells. (First article.)

Tools for Boring a Closed-Bottom Shell, M. H. Potter. Machy., vol. 25, no. 5, Jan. 1919, pp. 427-428, 6 figs. Types of blades used in boring heads and methods of grinding and setting blades.

See also MECHANICAL ENGINEERING, *Foundries (War Demands); Forging (Gun Forgings).*

General Science

CHEMISTRY

Analysis

Quantitative Analysis of Metals by Electrolytic Deposit Without Using External Source of Electrical Energy (Sur un procédé de dosage des métaux par dépôt électrolytique sans emploi d'une énergie électrique étrangère), Maurice François. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 20, Nov. 11, 1918, pp. 725-727. From a conductor resting on borders of platinum crucible containing sulphuric acid or similar reagent and salt to be analyzed a zinc or aluminum hook is suspended. Electrolytic action deposits metal in salt at bottom of crucible.

Method of Chromic Oxide Determination, W. C. Kiddell and Esther Kitredge. Chem. Engr., vol. 26, no. 12, Nov. 1918, pp. 457-458. Government chemists claim new method permits rapid handling of ore samples submitted for analysis. (To be concluded.)

The Quantitative Analysis of Small Quantities of Gases, H. M. Ryder. Jl. Am. Chem. Soc., vol. 40, no. 11, Nov. 1918, pp. 1656-1662, 3 figs. Description of apparatus for analyzing water vapor, CO_2, CO, O, H, N and methane; its manipulation; results of tests made to determine its accuracy.

Catalytic Exothermic Gas Reactions

Starting and Stability Phenomena of Ammonia Oxidation and Similar Reactions, F. G. Liljenroth. Gen. Elec. Rev., vol. 21, no. 11, Nov. 1918, pp. 807-815, 7 figs. Explains fundamental characteristics of catalytic exothermic gas reactions.

Methane

Methane, William Matisoff and Gustav Egloff. Jl. Phys. Chem., vol. 22, no. 8, Nov. 1918, pp. 529-575. Formulation of results of research up to date and their classification along physical (constants, specific properties, gas properties, industrial applications) and chemical (combustion, explosion, solubility, occlusion, industrial reactions) characteristics; notes on possibilities of research on methane both theoretical and practical.

Occluded Gases in Glass

Gases and Vapors from Glass, R. G. Sherwood. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 448-458, 8 figs. Author finds that under the influence of heat there are two distinct kinds of gaseous evolution products, namely, one associated with absorption—readily removable at 200 deg. cent., and other resulting from formation of new chemical equilibria. Also Jl. Am. Chem. Soc., vol. 40, no. 11, Nov. 1918, pp. 1645-1653, 9 figs.

Rare Earths

Observances on the Rare Earths (VIII). The Separation of Yttrium from Erbium; the Ratio Er_2O_3: 2 Er Cl_3, Edward Wichers, B. S. Hopkins and C. W. Balke. Jl. Am. Chem. Soc., vol. 40, no. 11, Nov. 1918, pp. 1615-1619. Comparison between cobalticyanide and nitrite precipitation methods; preparation of erbium material by nitrate fusion method; determination of ratio of erbium oxide to erbium chloride in seven analyses.

Structure of Matter

The Atomic Structure of Carborundum Determined by X Rays, C. L. Burdick and E. A. Owen. Jl. Am. Chem. Soc., vol. 40, no. 12, Dec. 1918, pp. 1749-1759, 4 figs. Measurements of angles of reflection of palladium X-rays from principal planes of crystal of carborundum and interpretation of measurements of intensities of reflection of different orders. Writers conclude elementary tetrahedron of carborundum differs from that of diamond only in a slight shortening of vertical axis and slight difference in displacement of carbon atoms from centers of tetrahedron.

MATHEMATICS

Elliptic Functions

On the Coefficients in the Expansions of Certain Modular Functions, G. H. Hardy and S. Ramanujan. Proc. Roy. Soc., vol. 95, no. A667, Nov. 7, 1918, pp. 144-155, 2 figs. Three theorems relating to properties of elliptic functions in powers of variable $Q = e^{n}$, where $n = \pi i \tau$.

Equations

On the Characteristics of Partial Derivative Equations of Second Order (Sur les caractéristiques des équations aux dérivées particlles du second ordre), E. Gau. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 19, Nov. 4, 1918, pp. 675-678. Invariant for characteristics of system by two quadratures.

Systems of Coördinates, G. H. Light. G. H. Light. Univ. of Colo. Jl. Eng., vol. 15, no. 1, Oct. 1918, pp. 23-27, 4 figs. Intrinsic equation of catenary and cycloid in system defined by length of arc and radius of curvature.

Heaviside Development Theory

Generalization of Heaviside Development Theorem (Généralisation du théorème du développement de Heaviside), Abraham Press. Revue Générale de l'Electricité, vol. 4, no. 19, Nov. 9, 1918, pp. 691-693. States that Carson (Phys. Rev., Sept. 1917, pp. 217-225) does not quite generalize theorem in question because the applied forces he considers have the exponential form; writer accordingly takes up case of any forced vibration by discussing general differential equation with constant coefficients.

Rectification of Arc

Notes on a Geometrical Construction for Rectifying Any Arc of a Circle, F. A. Lindemann. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 216, Dec. 1918, pp. 472-474, 1 fig. Process involving successive bisections and based on rapidly converging trigonometric series.

Single-Sided Surfaces

A Surface Having Only a Single Side, Carl Hering. Jl. Franklin Inst., vol. 186, no. 5, Nov. 1918, pp. 627-630, 4 figs. Further variations and minor corrections in study of surface generated by line moving along circle, always remaining in planes passing through axis of circle and simultaneously revolving around circle as axis at half angular rate of its movement along circle. Addendum to article in Aug. issue.

PHYSICS

Calorimeters

Calorimetric Lag, Walter P. White. Jl. Am. Chem. Soc., vol. 40, no. 12, Dec. 1918, pp. 1858-1872. Mathematical treatment of elimination of three lag effects of bodies external to calorimeters: (1) change in heat capacity of calorimeter, (2) thermal leakage, (3) loss dependent on jacket temperature.

The Conditions of Calorimetric Precision, Walter P. White. Jl. Am. Chem. Soc., vol. 40, no. 12, Dec. 1918, pp. 1872-1886. Expressing leakage effect as a function of time, thermal head for experimental period and leakage modulus of calorimeter, the effects of diminishing each of these on the values of other two are analyzed and rules for calorimetric precision are derived.

Crystals

Experimental Study on the Growth of Crystals (Etude expérimentale sur le développement des cristaux), René Marcelin. Annales de Physique, vol. 10, Sept.-Oct. 1918, pp. 185-188. Report of observations on paratoluidine. It appeared that these crystals grew not in depth but in surface by successive alluvions.

Formation and Optical Study of Sodium Chromate Crystals Having Four Water Molecules (Mode d'obtention et étude optique des cristaux de chromate de soude à 4 molécules d'eau), Lucien Delbaye. Bulletin de la Société Française de Minéralogie, vol. 41, nos. 4-5-6, Apr.-June 1918, pp. 80-93, 4 figs. Experimental research: Variation of three principal indices in terms of wave length; variation of apparent and true angles in turns of wave length; variation of position of bisectors in crystal in terms of wave length.

Crystalloluminescence

Crystalloluminescence (II), Harry B. Weiser. Jl. Phys. Chem., vol. 22, no. 8, Nov. 1918,

pp. 576-595, 1 fig. Survey of theories advanced by various investigators concerning nature of triboluminescence (property of many crystalline substances which emit phosphorescent light when rubbed or crushed); theory that it is the result of chemical action and is identical with crystalloluminescence so far as chemical reaction is concerned, differing only between themselves in physical process employed to bring about reaction; experiments with arsenic trioxide and with potassium sulphite.

Curie and Haüy Laws

Note on Curie and Haüy Laws (Sur les lois de Curie et de Haüy), C. Viola. Bulletin de la Société Française de Minéralogie, vol. 41, nos. 4-5-6, Apr.-June 1918, pp. 108-116. Demonstrates inter-connection of the two laws, Haüy's being developed analytically from Curie's differential fundamentals.

Curie Point in Iron

Curie's Point in Pure Iron and Ferrosilicon Alloys (Le point de Curie dans le fer pur et les ferro-siliciums), A. Sanfourche. Comptes rendus des séances de l'Académie des Sciences, vol. 167, no. 19, Nov. 4, 1918, pp. 683-685. Experimental measurements of termal manifestation at Curie's point. Alloys experimented on contained from 0.5 to 2.5 per cent silicon.

Density of Gases, Determination

An Accurate Method for Measuring the Density of Gases, O. Maas and J. Russell. Jl. Am. Chem. Soc., vol. 40, no. 12, Dec. 1918, pp. 1847-1852, 1 fig. Applicable to gases which can be condensed by liquid air or some other freezing agent. Known volume at known pressure and temperature is liquefied in bulb attached to containing vessel; bulb is then sealed off and gas weighed at room temperature.

Double-Suspension Mirror

The Double Suspension Mirror, L. Southerns. Lond., Edinburgh and Dublin Phil. Mag., vol. 36, no. 216, Dec. 1918, pp. 477-486, 8 figs. Theory of a method of observing deflections in a delicate balance; method a modification of "double suspension mirror."

Drops

Sounds Produced by Drops Falling on Water, A. Mallock. Proc. Roy. Soc., vol. 95, no. A667, Nov. 7, 1918, pp. 138-143, 6 figs. Theoretical determination of shape of cavity a falling sphere must make when it penetrates a fluid; experimental confirmation by instantaneous shadow photographs of falling shot.

Electromagnetic Vectors

The Electromagnetic Vectors, H. Bateman. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 459-481. Geometrical study of an electromagnetic field in relation to a moving observer and location of vectors with aid of two cones which at each point limit directions of forces acting on electric and magnetic charges moving with velocities less than that of light; expression of electromagnetic laws in terms of forces on unit electric and magnetic charges in motion and deductions relating to lines of force, derived from Hargreaves' theorems for space-time integrals; discussion of energy in electromagnetic field; development of theory in regard to amount of concealed energy in field of moving electron.

Explosion, Effects of

On the Rupture of Mirrors and Window-Panes by Explosions (Sur la rupture des glaces et des vitres par les explosions), P. Gaubert. Bulletin de la Société Française de Minéralogie, vol. 41, nos. 4-5-6, Apr.-June 1918, pp. 65-67. Explanation for shapes commonly presented by pieces into which a large plate breaks as result of explosion.

Fluorescence

The Physical Characteristics of X-Ray Fluorescent Intensifying Screens, Millard B. Hodgson. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 431-435, 2 figs. Fluorescence of various materials discussed from point of view of photographic efficiency; qualitative determination of spectral distribution of fluorescence from calcium tungstate; photographic efficiency of characteristic radiation from silver, tungsten, platinum and lead.

Fluorescence (La fluorescence), Jean Perrin. Annales de Physique, vol. 10, Sept.-Oct. 1918, pp. 133-159. Destruction of fluorescent bodies by emission of fluorescence; influence of temperature on intensity of emission; molecular and atomic fluorescence; limiting power; fluorescence of concentrated solution; fragility of fluorescent molecules.

Gravitation

On a Peculiarity of the Normal Component of the Attraction Due to Certain Surface Distributions, Ganesh Prasad. Lond., Edinburgh and Dublin Phil. Mag., vol. 36, no. 216, Dec. 1918, pp. 475-476. Cases in which component N of Newtonian attraction at point P along normal through P meeting surface at O tends to no limit as P approaches O along normal.

Impact

The Photographic Study of Impact at Minimal Velocities, C. V. Roman. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 442-447, 6 figs. Graphs showing relation between coefficient of restitution and velocity of impact for polished spheres of equal radius of brass, aluminum, hard bronze, white marble, and lead.

Inflammability of Gaseous Mixtures

The Inflammation of Mixtures of Methane and Air in a Closed Vessel, Richard Vernon Wheeler. Jl. Chem. Soc., vols. 113 and 114, no. 673, Nov. 1919, pp. 840-859, 7 figs. Results of experiments in spherical vessels. Giving data on maximum pressures developed, rates of development of pressure, and speeds of propagation of flame.

Ionization

Ionization of Mercury, Sodium and Potassium Vapors and the Production of Low Voltage Arcs in These Vapors, T. C. Hebb. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 482-490, 2 figs. Concludes from experiments that: Potassium vapor can be ionized at 1.6 volts; sodium vapor at 2.5 volts; D lines of sodium can be excited at less than 1.0 volt; sodium and potassium arcs in mercury vapor can operate below their resonance potentials and as low as 1.4 for sodium and 0.5 volts for potassium; mercury spectrum can be produced at 0.5 volt in atmosphere of mercury and potassium.

Latent Heat of Fusion

Latent Heat of Fusion as the Energy of Molecular Rotations, Kōtarō Honda. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 425-430. Tables and calculations, based on Landolt and Börnstein's values, which lead writer to assert that latent heat of fusion consists of energy of rotation of molecules gained during fusion.

Light Emission

On the Light Emitted from a Random Distribution of Luminous Sources, Lord Rayleigh. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 216, Dec. 1918, pp. 429-449, 3 figs. Mathematical treatment of probable expectation of intensity in any direction. By "expectation" is meant the mean of a large number of independent trials, or combinations, in each of which the phases are redistributed at random. Sonorous vibrations are considered but the results are shown to be applicable to electric vibrations.

Light Polarization

The Light Scattered by Gases: Its Polarization and Intensity, R. J. Strutt. Proc. Roy. Soc., vol. 95, no. A667, Nov. 7, 1918, pp. 155-176, 5 figs. Measurements of intensity of vibrations parallel to existing beam of light scattered at right angles by gases and vapors; particular study of behavior of helium; evaluation of intensity of scattering by different gases in terms of refractivity; photographs of polarizations of ether, vapor and nitrous oxide.

Liquid Films

The Stratification of Liquid Films (La stratification des lames liquides), Jean Perrin. Annales de Physique, vol. 10, Sept.-Oct. 1918, pp. 160-184. Result of Johonnott's microscopical examination of soap bubbles; superficial tension of soap solutions; law of multiple thicknesses; chemical separation by simple extension of free surfaces.

Pitched Baseball

A Pitched Baseball, Willard W. Griffin. Sci. Am. Supp., vol. 87, no. 2244, Jan. 4, 1919, pp. 12-14, 3 figs. Mechanical analysis of a "floater" and other curved ball paths.

Radioactivity

The Problem of Radioactive Lead, Theodore W. Richards. Science, vol. 49, no. 1253, Jan. 3, 1919, pp. 1-11. Account of experimental researches; hypothesis concerning disintegration of uranium; hypothetical calculation of atomic weight of uranium-lead; solubility of two kinds of lead nitrate; comparison of properties of different kinds of lead. Presidential address before Am. Assn. for Advancement of Science.

Sound, Standard of

A Possible Standard of Sound, Chas. T. Knipp. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 491-492, 1 fig. Adjustment of mercury vapor trap of pyrex glass to furnish sound of desired pitch. From paper presented at meeting of Am. Phys. Soc.

Specific Heat

Specific Heat Determination at Higher Temperatures, Walter P. White. Am. Jl. Sci., vol. 47, no. 277, Jan. 1919, pp. 44-59, 4 figs. Experimental technique at temperatures up to 1400 deg. cent. by method of mixtures; modifications in furnaces and in methods of transferring to calorimeter; variability of heat losses attending dropping of hot bodies into water; use of aneroid calorimeters.

Silicate Specific Heats, Walter P. White. Am. Jl. Sci., vol. 47, no. 277, Jan. 1919, pp. 1-43, 4 figs. Experimental determination for temperatures from 100 to 1400 deg. cent. by dropping from furnaces into calorimeters; checks and precautions employed; two methods for determining true or atomic heats from interval heats. Paper extends scope of writer's previous communications.

The Specific Heat of Platinum at High Temperatures, Walter P. White. Phys. Rev., vol. 12, no. 6, Dec. 1918, pp. 436-441. Redetermination of specific heat from 100 to 1300 deg. cent. with precision of 0.3 per mile. Results agree with those of Gaede, Plato, Corbino, Magnus and Fabaro.

Spectra

The Origin of Spectra, J. C. McLennan. Proc. Phys. Soc. Lond., vol. 31, no. 176, Dec. 15, 1918, pp. 1-29, 14 figs. Outline of investigations undertaken since Frank and Hertz' measurements of mercury-vapor ionization potential and further experimental researches including also vapors of zinc, cadmium and magnesium. Ultraviolet region investigated with a fluorite spectrograph and extreme ultra violet region with a vacuum grating spectrograph. General discussion of results obtained by writer and other investigators.

On the Ultraviolet Spectra of Magnesium and Selenium, J. C. McLennan. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 216, Dec. 1918, pp. 450-460, 2 figs. Records of investigations with Hilger quartz spectrograph and another specially constructed fluorite spectrograph showed 12 new lines in selenium spark spectrum between $\lambda = 2200$ A°. V. and $\lambda = 1850$ A°. U., five lines in selenium are between same limits, and reversal at $\lambda = 2200$ A°. U. in absorption spectrum of selenium metal in carbon arc.

On Fundamental Frequencies in the Spectra of Various Elements, J. C. McLennan. Lond., Edinburgh & Dublin Phil. Mag., vol. 36, no. 216, Dec. 1918, pp. 461-471, 7 figs. Extensive experimental research with photographic records. It is concluded that when zinc and cadmium vapors respectively are bombarded by electrons whose kinetic energy is gradually increased, monochromatic radiation is suddenly emitted by vapor when impact voltage reaches certain value, beyond which no additional relation is produced; also that when a Bunsen flame is fed with vapor of heated zinc, it is possible to obtain monochromatic radiation of wave-length $\lambda = 3075.99$ A°. U.

Welsbach Mantle

A Physical Study of the Welsbach Mantle, Herbert E. Ives, E. F. Kingsbury and E. Karrer. Jl. Franklin Inst., vol. 186, no. 5, Nov. 1918, pp. 585-625, 21 figs. Extension of Ruben's work on thoria-ceria mixtures to large family of such combinations; from investigation of conditions under which visible absorption bands of ceria and other materials appear and disappear, an explanation is offered of different behavior of mantle in flame and cathode-discharge heating; attempt to fix possible attainable efficiencies of gas-light production by present methods (Concluded from p. 438, Oct. 1918.)

HEAT TREATMENT OF LOW-CARBON STEEL

Characteristic Structures Found in Steel, Their Formation by Heat Treatment and the Effect Each Has on the Quality of the Steel

By W. M. Wilkie,[1] Toronto, Ont.

Steel is made up of iron combined with certain percentages of carbon, manganese, silicon, phosphorus, sulphur and other elements, each one of which by its presence in varying quantities imparts some special quality to the steel. It is, however, the writer's intention to confine himself to a study of the more usual combinations of iron and carbon that exist in low-carbon steels, for the whole subject of heat treatment is really a study of the different forms or phases in which the various combinations of iron and carbon exist, and the conditions under which they are formed. That is, knowing the particular quality a certain form or phase imparts to steel, and the treatment required to produce it, we are in a position to prescribe the treatment necessary for producing steel of any desired quality.

From microscopic examinations of polished and etched sections of steel, it has been found that there are a number of characteristic structures under which steel exists, each being the result of some special treatment. To determine these characteristic forms and the reason for their formation, a study should be made of the different kinds of treatment that steel receives in ordinary commercial practice and the results of these various treatments. The subject may be divided as follows:

1 Unworked steel, i.e., cast steel $\left\{\begin{array}{l}\text{cooled slowly}\\ \text{cooled rapidly}\\ \text{reheated}\end{array}\right.$

2 Hot-worked steel $\left\{\begin{array}{l}\text{cooled slowly}\\ \text{cooled rapidly}\\ \text{reheated}\end{array}\right.$

Cast Steel Cooled Slowly

In molten steel the carbon exists as chemical compounds of iron and carbon of varying composition, called carbides. The most common of these has the composition FeC_3 and is called cementite. These carbides are found dissolved in the molten iron in the same way as salt is dissolved in water; also as the steel solidifies, the carbides continue in solution and form what is known as a "solid solution."

The solid solution of iron and the carbide FeC_3 is called austenite, and is the usual form or phase that iron is found in just after freezing.

Austenite, owing to its instability at lower temperatures, is rarely ever found in steel unless special precautions are taken, such as by cooling very rapidly from temperatures above 1000 deg. cent. (1768 deg. fahr.) It has a crystalline structure, which becomes coarser the slower the steel is cooled, due to the fact that as no mechanical work has been done on the steel, adjacent crystals tend to assume the same orientation and merge into a larger crystalline grain. Such slowly cooled, coarse-grained steel is brittle, has minimum tenacity and toughness, and can only be used where it is possible to make up strength by using large masses of metal.

Along with the growth in the size of the grains, the rate of cooling is uniform until a temperature somewhere between 900 deg. cent. and 700 deg. cent. (1652 and 1292 deg. fahr.) is reached. At this point the rate of cooling is gradually retarded, until finally the temperature becomes either stationary or even slightly higher. After a short interval the temperature will again fall at a gradually increasing rate until it becomes uniform, at which it continues to cool to atmospheric temperatures.

The explanation of this peculiar phenomenon is that a change occurs in the structure of the steel during this change of temperature, caused by the austenite, now having reached a temperature at which it is no longer stable, proceeding to change into the more stable phases of lower temperatures. This change is accompanied by a liberation of heat, which explains the change in the rate of cooling. A similar but reverse action takes place when steel is being heated.

The range of temperature within which this change occurs is called the critical range, while the upper and lower limits of this range are known as the upper and lower critical points. The lower point is about 690 deg. cent. (1274 deg. fahr.) for all percentages of carbon content, whereas the upper point ranges from 900 deg. for pure iron to 690 deg. for steels containing 0.85 per cent carbon. These points also vary slightly with the amounts of other elements besides carbon present, also depending on whether the steel is being heated or cooled. The critical range and its limits are important points to remember in heat treatment, and it is necessary to become thoroughly familiar with the reactions that occur in this range.

The slow-cooling steel under consideration has now reached the upper critical point where the martensite is no longer stable and begins to change into some more stable form such as pearlite, ferrite or cementite.

Pearlite is a definite mechanical (not chemical) mixture of the carbide FeC_3 with pure iron or "ferrite," with a carbon content of 0.85 per cent. Steels having such a carbon percentage will, after annealing, be all pearlite and are known as "eutectoid" steels. If the carbon content is *less* than 0.85 per cent, all the carbon is combined with iron to form the carbide FeC_3 or cementite, which by the addition of a further amount of iron immediately is converted into pearlite, while any excess iron is left free. Such steel is called hypoeutectoid steel, and consists of pearlite and ferrite when in the annealed condition.

If the carbon content is *over* 0.85 per cent, there will be an excess of cementite over the amount required to make pearlite from the free iron present, and so we have the two phases, cementite and pearlite, when the steel is annealed. Such steel is known as hypereutectoid steel.

Pearlite is a constituent of all slowly cooled steels, the greater the proportion of carbon—and hence of pearlite—the stronger and tougher and less ductile will be the steel, until the eutectoid composition is reached, when the steel has maximum strength, as all additions of carbon above this composition only result in the formation of cementite, which has no strengthening power.

Pearlite also by its ability to take up free ferrite and change into austenite is the hardening constituent of steel, so that eutectoid steel is the composition that has maximum hardening powers, though eutectoid steels are not necessarily the hardest, as hypereutectoid steels may be harder as the result of the hardness caused by the presence of cementite.

Ferrite is the name of pure iron and it is the constituent of all low-carbon slowly cooled steels. It is very soft, ductile, relatively weak, and has no hardening power.

Cementite is a substance about which little is known. It is a definite chemical compound, FeC_3, and it may be assumed that it is very hard and brittle, and therefore lacks tenacity and ductility. It has no hardening power beyond the extreme hardness it itself confers on the steels.

The properties of these three constituents of steel as given by Howe are set forth in Table 1.

When the slow-cooling steel has reached the upper critical point, it will be coarse grained because of the very slow cooling. At this point each grain of austenite tends to transform into the pearlite composition by throwing off the excess ferrite or cementite it contains, and if the cooling is carried on with sufficient slowness, it will be found that by the time the lower critical range is reached each original grain of austenite has changed into the pearlite or eutectoid composition, while the excess iron in the hypo-eutectoid steels, or the excess cementite in the hypereutectoid steels, has been liberated as follows:

---

[1] Imperial Munitions Board, Toronto.

Paper presented at a meeting of the Ontario Section of The American Society of Mechanical Engineers, Toronto, April 18, 1918.

TABLE 1 PROPERTIES OF CONSTITUENTS OF STEEL

Constituent	Tensile strength, lb. per sq. in.	Elongation, per cent	Hardness	Hardening power
Ferrite..........	50,000	40	Soft	None
Pearlite.........	125,000	10	Hard	Maximum
Cementite.......	5,000 ?	0	Very hard	None

1 As a film or envelope around the original grains
2 Between the cleavage planes of the crystalline grains
3 As a combination of both.

The first form results with fairly rapid cooling, whereas the second form is the result of very slow cooling.

As the steel cools past the lower critical range the changes are all completed, and any further cooling has no effect on the internal structure, provided it is not rapid enough to set up strains.

Having followed the changes in a slow-cooled cast steel, it is found that the final condition is a coarse-grained, softened steel, which owing to its coarse-grained structure lacks strength, toughness and ductility, but is relatively soft, and has for its constituents the phases pearlite, combined with either ferrite or cementite, depending on the carbon content.

Cast Steel Cooled Rapidly

In cooling steel very rapidly, by quenching it in oil or water, we find marked differences from the slowly cooled steel. First, the grain structure is finer, the growth of the grains being prevented. Second, the steel is very hard and brittle, because the reaction in which austenite transforms into pearlite, with a residue of ferrite or cementite, can only take place completely when the cooling is very slow. If the steel is cooled rapidly, the reaction only partially takes place, and as a result there are a number of new phases formed which are really part-way transformations between the austenite phase and the phases of soft steel.

The most important of these forms is martensite. This is really an allotropic form of austenite, whose most characteristic features are its needle-like structure, with the crystals crossing each other at 60 deg., and its extreme hardness. It is formed by quenching steel in water, if the pieces are fairly large, or in oil in case of small objects, from above or near the upper critical point. This rapid cooling causes rapid contraction, which sets up great pressures and results in the crystals assuming the structure indicated above.

Martensite is the form or phase giving maximum hardness to steel, so that the more rapid the cooling and, consequently, the greater the amount of martensite, the harder and more brittle will be the steel. Extremely brittle steel is, however, of very little use commercially.

If the steel instead of being quenched in water is either allowed to cool slowly to the middle critical range and then quenched, or is quenched in oil in case of small sections, another form, called troostite, is formed. This is a further stage in the transformation from austenite into pearlite, i.e., the grains have gone a step further toward reaching the eutectoid composition. Troostite occurs in dark-colored, irregular areas or nodules, and is nearly always accompanied by martensite and sorbite. It is slightly softer and has more ductility and toughness than martensite.

If the steel instead of being quenched in oil or water is cooled rapidly in air, or a large piece of steel is quenched in oil, a new constituent called sorbite is formed, which is another stage in the transformation of austenite into pearlite. It is considerably softer than martensite, and in fact is not a constituent of hardened steel. Its properties more nearly approach that of pearlite, i. e., it is stronger, harder and less ductile than pearlite, but softer and more ductile than troostite. Its composition also approaches more closely to the pearlite composition than the solid solution of iron and ferrite found in austenite; in fact, sorbite is the last stage in the transformation from austenite to pearlite.

Accordingly, unworked steel cooled slowly contains the phases of soft steel, but owing to the coarse-grained crystalline structure it is brittle and lacks strength and ductility. Similarly with rapidly cooled unworked steel the rapid cooling tends to retard the growth of large grains, but unless great precautions are taken to cool the steel very rapidly, it will still have a fairly coarse granular structure, which, combined with the brittleness caused by rapid cooling, leaves a material having little commercial value.

Cast Steel Reheated

To overcome these difficulties it is necessary to give the steel some special heat treatment—in this case, annealing. Theoretically, in annealing the steel should be heated to the upper critical point, and then cooled slowly, but the rate of cooling has to be varied, depending on the particular steel required.

The theory of this treatment is that as the steel is heated above the lower critical point, the phases of softened steel, i. e., pearlite, ferrite, and cementite, tend to change into austenite. This reaction continues through the critical range accompanied by the absorption of heat which causes a retarding in the rate of heating, similar but opposite to the action in cooling, and when the upper critical point is reached it is found that the steel has been all converted into martensite, provided sufficient time has been given in heating to permit this reaction to occur completely. The result of this transformation is to break the coarse-grained crystals into a finer-grained or even an amorphous structure.

Such is the treatment required theoretically, but in cast steel there are certain conditions that prevent the reaction from occurring as expected, so that it becomes necessary to soak the steel for a long time at temperatures considerably above the upper critical point before obtaining an annealing action. These conditions will be discussed in detail under annealing.

In the case of cast steels which have been quenched (unlikely in actual practice), we have the usual hardening of steel. Any reheating will result in changes similar to tempering. Hardening and tempering will be discussed in later paragraphs.

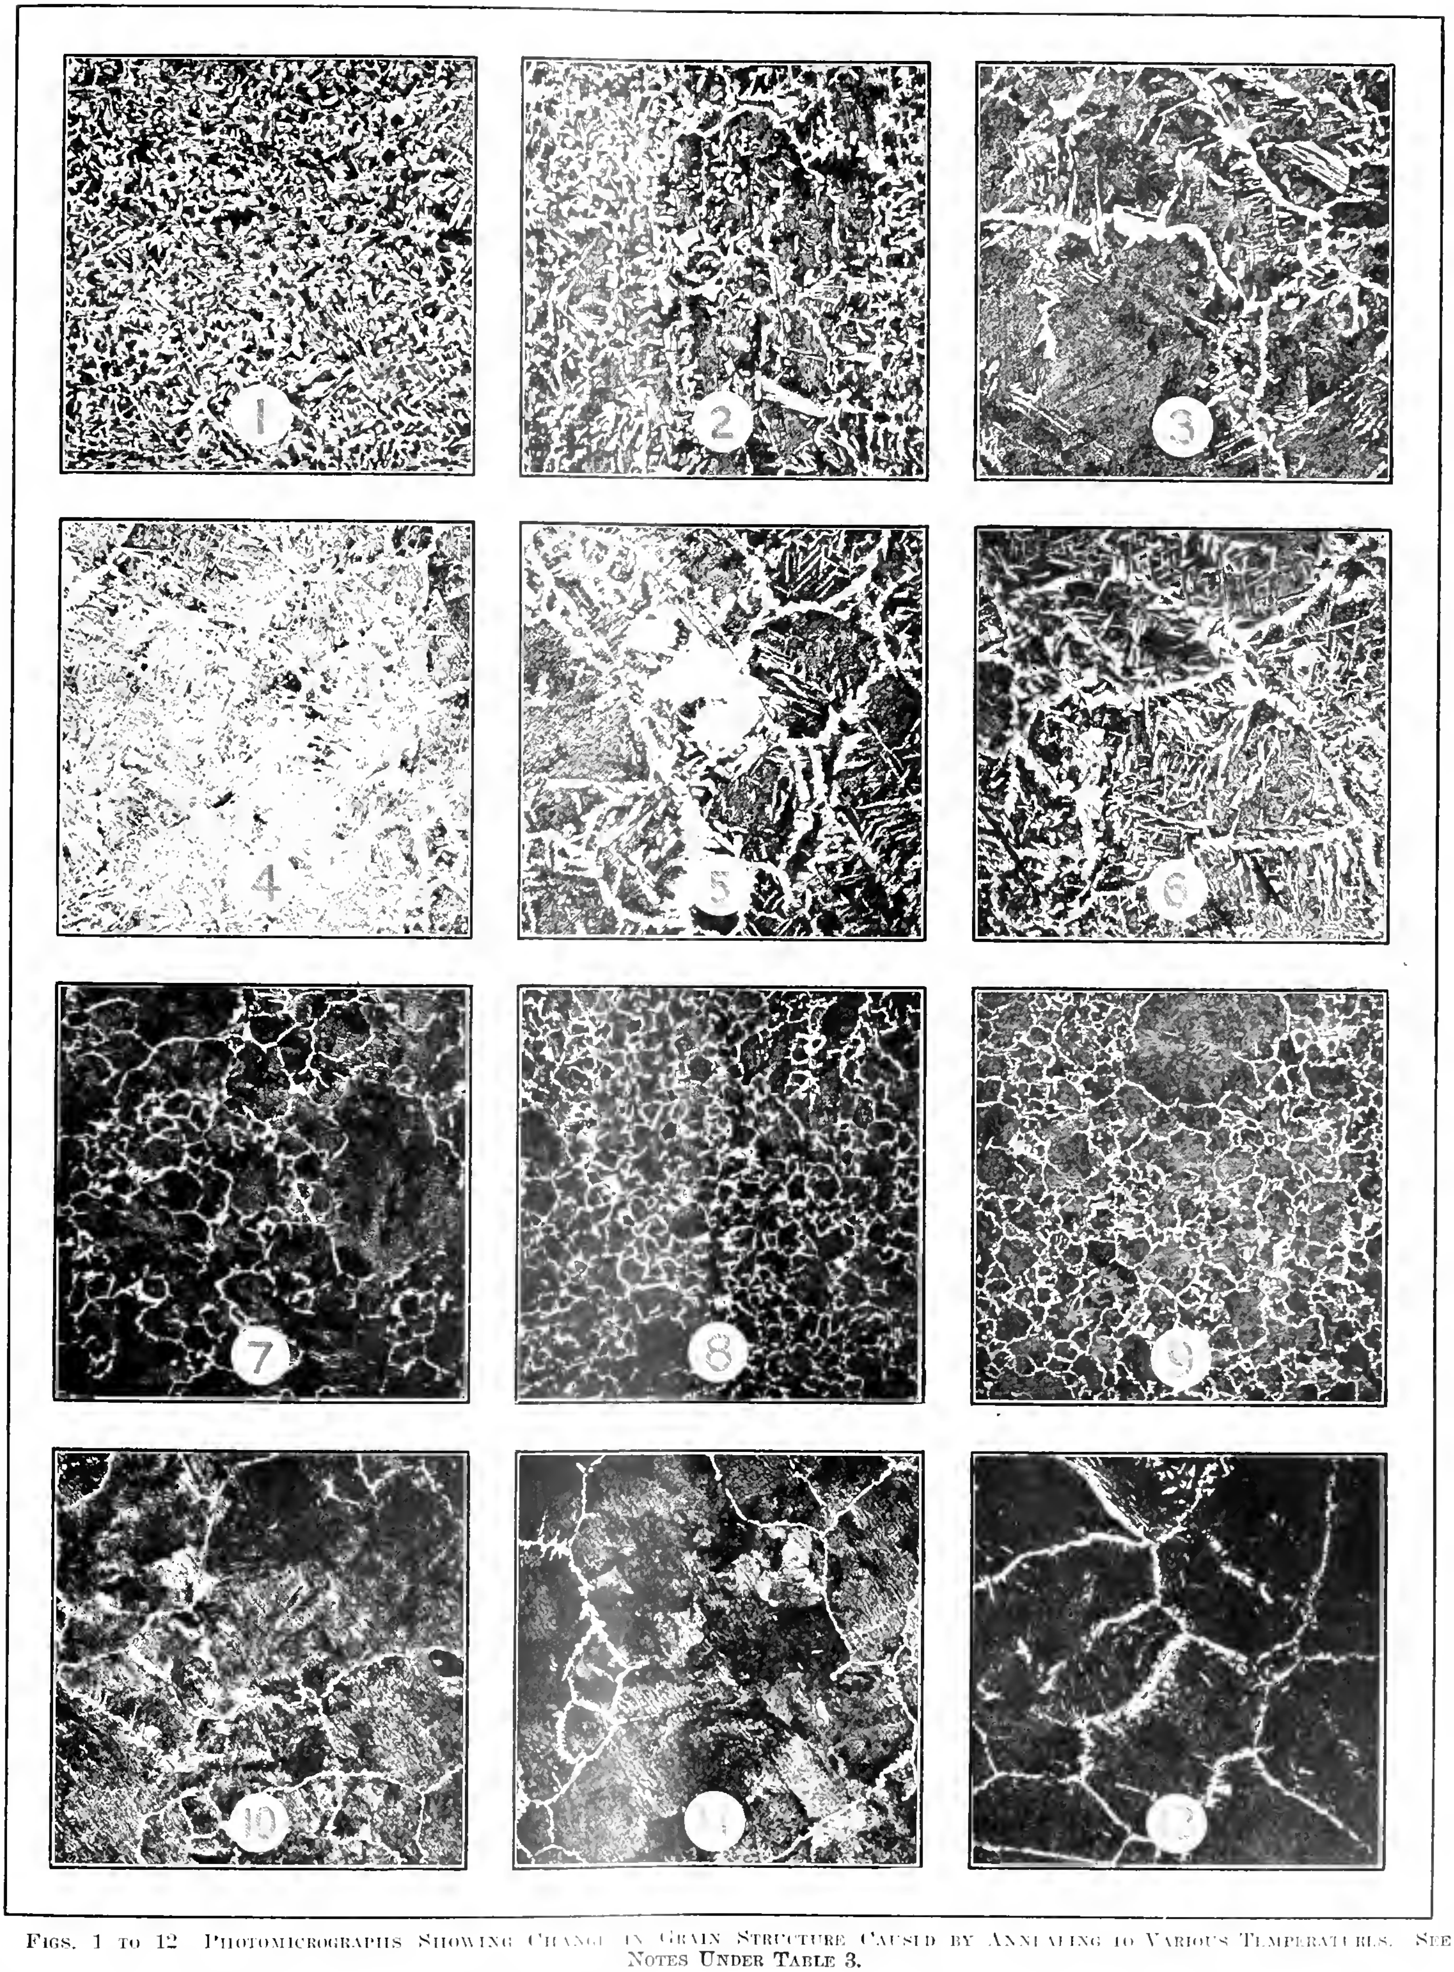
Hot-Worked Steel Cooled Slowly

In cast steel it was found that the size of grain structure was dependent on the rate of cooling, but with steel subjected to mechanical treatment such as rolling or forging, we find that the crystalline growth is much slower, if not altogether discontinued, during the time the steel is being so treated. The extent of this retardation of the crystalline growth is controlled by:

1 *The nature of the work being done.* Light hammering, with only a slight reduction in size, may leave the steel almost like cast steel, while pressure under a hydraulic press, combined with a large reduction in area will leave it with a fine-grained or even amorphous structure. The latter is an ideal condition.
2 *The temperature at which work was stopped.* As soon as we discontinue working the steel the growth of size of crystalline grain again commences and continues to the upper critical range.
3 *Rate of cooling from time of completion of work to the upper critical point.*

If steel is cooled slowly from the temperature at which work was stopped (especially if this temperature was high) to the upper critical point, the result is a coarse-grained structure of the phases of softened steels. Due to the relatively large grains of pearlite the tensile results, including the elongation, will be found to be low. This is a condition frequently met in the forging of shells where the finishing temperatures are around 1800 deg. fahr. or even higher. In high-carbon heats the forging manufacturers attempt to soften the steel by long-continued cooling, and if this rate of cooling is sufficiently slow we reach the above conditions and find heats failing on yield with an ultimate strength of about 43 tons, where the normal results should be 50 tons and over. To overcome this condition it is necessary to carefully anneal the steel to remove the coarse-grained structure.

Where the mechanical treatment is continued to the upper critical point the structure is fine-grained and is in its ideal condition, but the cost of working steel down to this temperature usually forbids it, so that any crystalline structure that is formed between the finishing temperature and the upper critical point must



Figs. 1 to 12 Photomicrographs Showing Change in Grain Structure Caused by Annealing to Various Temperatures. See Notes Under Table 3.

be removed by reheating (annealing) the steel to the upper critical point and then cooling either slowly or rapidly, depending on the product required.

Annealing of Steel. The purpose of annealing steel is—

1 To increase the softness and ductility of steel in cases where it is too hard for machining;
2 To remove strains and refine grain structure and reduce brittleness or other defects caused by:
   a High finishing temperature while hot-working, leaving a coarse-grained structure
   b Coarse granular structure due to slow cooling as in castings
   c Strains caused by cold-working of steel below critical temperature;
3 To soften steels too hard and brittle as the result of too rapid cooling.

In annealing the operation consists in (1) slowly raising the steel to its upper critical temperature; (2) holding it or soaking it at this temperature for a certain time depending on size of piece being treated and condition of previous treatment; and (3) cooling from annealing to atmospheric temperature.

Theoretically, as the steel is heated to the lower critical point the usual transformation from the phases of softened steel to austenite is commenced, and continues through the critical range, so that when the upper critical point is reached the steel should be all austenite. As a result of this transformation all preëxisting structures, no matter how coarse, are obliterated and the mass assumes an amorphous structure, providing sufficient time has been taken in heating to permit these changes to occur.

Further, if the temperature is carried above the upper critical point the tendency is for this amorphous structure to again become crystalline. Hence, in annealing steel its temperature should theoretically be raised to the upper critical point only, but practically there are conditions that modify this. For example, in cast steels we find that temperatures considerably higher (as much as 100 deg. cent. above the theoretical temperatures), combined with long soaking, are required to break up the coarse-grained structure. The reason for this is rather obscure. One theory that has been advanced claims that each grain in cast steel is surrounded by a film of sulphides, phosphides and silicides of iron which prevents the crystals from breaking up under ordinary treatment, but with long soaking at high temperatures these impurities tend to migrate to the center of the grains and leave the surface of the crystals free to break up.

TABLE 2 ANNEALING TEMPERATURES FOR STEEL

Range of Carbon Content	Range of Annealing Temperatures	
	Deg. Cent.	Deg. Fahr.
Less than 0.12 per cent.	875 to 925	1607 to 1697
0.12 to 0.25 per cent.	840 to 870	1544 to 1598
0.30 to 0.49 per cent.	815 to 840	1499 to 1544
0.50 to 1.00 per cent.	790 to 815	1454 to 1499

Mechanical work on steel seems to have the same effect, i. e., it breaks up this intercrystalline film, and as a result we find that the more a piece of steel has been worked the closer the annealing temperatures can be kept to the upper critical point, while the nearer the steel is to the unworked or cast condition the higher the temperatures must be. The ranges of temperatures given in Table 2 have been recommended by the Committee on Heat Treatment of the American Society for Testing Materials.

The time of soaking depends largely upon the size of the object being annealed, but sufficient time should be given to permit the object to be heated throughout to the annealing temperature and allow the internal changes to occur. Pieces 12 in. thick require about one hour.

HOT-WORKED STEEL COOLED RAPIDLY

The rate of cooling after annealing is controlled by the product required. If a maximum softness and ductility is desired, i. e., for easy machining, we cool as slowly as possible, by either burying the article in a bed of insulating material or allowing it to cool in the furnace. If, however, we wish to retain a certain amount of hardness and strength we must cool faster, as in air or, if a very low-carbon steel, in water, but to do so we must sacrifice a certain amount of ductility and softness. As a general rule, the lower the carbon the more rapid may be the cooling. For example:

a Steels with carbon contents below 0.15 per cent can be quenched in water and remain ductile and at same time have maximum hardness and strength.

b Steels with carbon contents below 0.20 per cent can be quenched in oil with results similar to 0.15 per cent carbon quenched in water.

c Steels with carbon above 0.30 per cent cannot be cooled so rapidly without destroying the ductility of the steel and so must be either cooled in the furnace, or in the air when extreme softness is not required.

The size of objects must also be considered along with the product desired. Other things being equal, the larger the object the more quickly must it be cooled, so long as the cooling is not too rapid to set up strains.

As an example of the effect of rate of cooling on the strength of steel, we have a system of strengthening steels on high-explosive shells known as the Sandberg air-cooling method. By this method air at pressures ranging from 6 oz. to 15 oz., usually around 10 oz., is either passed around the shell forging or forced to impinge on the revolving shell in such a way that a shell that would normally cool in about thirty minutes or more in the open air, is cooled in six to eight minutes. As a result the ultimate strength is raised from 4000 to 10,000 lb., with an increase in the elastic ratio but with very little variation in the ductility of the steel. This process is really an intermediate treatment between annealing and the regular hardening of steel, due to the formation of sorbite, which, as explained before, is a transformation phase between martensite and pearlite. Another way to get this sorbitic steel is to first quench steel from the upper critical range, thus retaining its fine-grained structure but leaving the steel very hard and without ductility. The steel is now reheated close to but below the lower critical range, say, from 500 to 650 deg. cent. (932 to 1202 deg. fahr.), when it loses its hardness and becomes ductile. The reason for this is that the steel has been changed from martensite to sorbite. This is really a hardening and tempering treatment, but is referred to here because it is sometimes called a double annealing treatment.

Photomicrographs of Annealed Steel. The photomicrographs reproduced in Figs. 1 to 12 illustrate graphically the distinct change in grain structure caused by annealing to various temperatures. Figs. 1 to 6 apply to one grade of steel, *A*, and Figs. 7 to 12 to another grade, *B*. The properties of these steels, after ordinary forging, but before annealing, are given in Table 3.

TABLE 3 ANALYSES AND PROPERTIES OF ANNEALED STEELS *A* AND *B*

Steels	Carbon, per cent	Manganese, per cent	Phosphorus, per cent	Sulphur, per cent	Stretch at 19 tons	Ultimate breaking load, tons	Elongation, per cent
A	0.40	0.61	0.062	0.057	0.0	40.3	26.0
B	0.55	0.80	0.058	0.057	0.0	47.9	18.5

HEAT TREATMENT

Figs. 1 and 7: Samples heated to 1500 deg. fahr., held for 2 hr., withdrawn, and cooled in air.

Figs. 2 and 8: After the above heat, samples were heated to 1600 deg. fahr., held for 1½ hr., withdrawn, and cooled in air.

Figs. 3 and 9: After the above heats, samples were heated to 1700 deg. fahr., held for ½ hr., withdrawn, and cooled in air.

Figs. 4 and 10: After all the above heats, samples were heated to 1900 deg. fahr., held for ½ hr., withdrawn, and cooled in air.

Figs. 5 and 11: After all the above heats, the samples were heated to 2100 deg., held for 20 min., withdrawn, and cooled in air.

Figs. 6 and 12: After all the above heats, samples were heated to 2275 deg. fahr., held for 20 min., withdrawn, and cooled in air.

In samples *A* the grain structure increases progressively from the start. In samples *B* the grain is finest at 1600 deg. fahr., Fig. 8, and increases thereafter. At 1900 deg. fahr., Fig. 10, signs of overheating appear, while samples *A* show damage only in Fig. 6, at 2275 deg. fahr.

Hardening of Steel. The most common constituents of hardened steel are martensite and troostite, and as we know the conditions under which they are formed, it is only necessary to treat the steel so as to produce either or both, depending on the hardness required.

To obtain martensite the steel must be raised to the upper critical range so as to transform the pearlite and ferrite, or pearlite and cementite, into austenite. We must not let the temperature rise above the upper critical point, as by so doing we coarsen the structure, and our aim should be to keep this as fine as possible. So we should quench the steel just as it issues from the upper critical range in the quenching medium selected, due to the fact that long exposures to temperatures above the critical point will increase the grain size. However, in deciding on the temperatures to be used we must consider the previous work and treatment given the steel. For example, a piece of cast steel will require considerably higher temperatures for reasons similar to those given under annealing, while steel that has had considerable work done on it (especially when work is continued down to the upper critical range) need only be heated to the upper critical range before quenching. The hardening temperatures in Table 4 are given by E. F. Houghton & Co.

TABLE 4 RELATION OF HARDENING TEMPERATURE TO CARBON CONTENT

Carbon Content	Hardening Temperature to Use	
	Deg. Cent.	Deg. Fahr.
Up to 0.20 per cent	871 to 899	1600 to 1650
0.20 to 0.35 per cent	843 to 871	1550 to 1600
0.35 to 0.50 per cent	815 to 843	1500 to 1550
0.50 to 0.70 per cent	787 to 815	1450 to 1500
0.70 to 0.90 per cent	760 to 787	1400 to 1450
0.90 per cent or over	732 to 760	1350 to 1400

It is difficult in quenching steel to control the percentage of martensite and troostite that will result, or, in other words, to get uniform results from hardening alone, as the various factors that control these percentages as size of piece, rate of cooling, etc., vary so much. So the practice is to endeavor to get the maximum amount of martensite by as rapid a cooling from above critical point as is permissible without unduly setting up cooling strains which might rupture the metal. This leaves the metal too hard and brittle for ordinary requirements, but by tempering we can arrive at any degree of hardness or toughness required.

Steel is most commonly quenched in oil or water. In either case care must be taken, especially with high-carbon steels, to prevent cracking as the result of strains set up by too rapid cooling. If oil or water is used the object should be withdrawn from the bath before its temperature has fallen below 100 deg. cent. (212 deg. fahr.), and the drawing or tempering treatment should follow immediately.

Hot-Worked Steel Reheated (Tempering)

Steel that has been hardened is generally harder and more brittle than is necessary, and in order to bring it to the condition that meets our requirements a treatment called tempering is used. This increases the toughness of the steel, i. e., decrease the brittleness at the expense of a slight decrease in hardness.

There are several theories to explain this reaction, but generally it is only necessary to remember that in hardening we quench steel from the austenite phase, and, due to this rapid cooling, the normal change from austenite to the eutectoid composition does not have time to take place, and as a consequence the steel exists in a partially transformed and unstable condition at ordinary atmospheric temperatures. But owing to the strains and rigidity set up by this rapid cooling the steel is unable to change into its more stable phase until these strains are removed by the application of heat. The higher the heat, the greater the transformation into the softer phases. As the transformation takes place, a certain amount of heat of reaction, which under slow cooling would have been released in the critical range, is now released and helps to cause a further reaction, the result of which is that if a piece of steel is heated to a certain temperature and held there, the tempering color, instead of remaining unchanged at this temperature, will advance in the tempering-color scale as it would with increasing temperature. This means that the tempering colors do not absolutely correspond to the temperatures of steels, but the variations are so slight that we can use them in actual practice.

Temperatures to Use. As soon as the temperature of the steel reaches 100 deg. cent. (212 deg. fahr.) the transformation begins, increasing in intensity as the temperature is raised, until finally when the lower critical range is reached, the steel has been all changed into the ordinary constituents of unhardened steels.

If a piece of polished steel is heated in an ordinary furnace, a thin film of oxides will form on its surface. The colors of this film change with temperature, and so, in tempering, they are generally used as an indication of the temperature of the steel. The steel should have at least one polished face so that this film of oxides may be seen.

An alternative method to the determination of temper by color is to temper by heating in an oil or salt bath. Oil baths can be used up to temperatures of 500 deg. fahr.; above this, fused-salt baths are required. The article to be tempered is put into the bath, brought up to and held at the required temperature for a certain length of time, and then cooled, either rapidly or slowly. This takes longer than the color method, but with low temperatures the results are more satisfactory, because the temperature of the bath can be controlled with a pyrometer. The tempering temperatures given in Table 5 are taken from a handbook issued by the Midvale Steel Co.

TABLE 5 TEMPERING TEMPERATURES FOR STEELS

Temperature for 1 hour		Color	Temperature for 8 min.		Uses
Deg. F.	Deg. C.		Deg. F.	Deg. C.	
370	188	Faint yellow	460	238	Scrapers, brass-turning tools, reamers, taps, milling cutters, saw teeth
390	199	Light straw	510	265	Twist drills, lathe tools, planer tools, finishing tools
410	210	Dark straw	560	293	Stone tools, hammer faces, chisels for hard work, boring cutters
430	221	Brown	610	321	Trephining tools, stamps
450	232	Purple	640	337	Cold chisels for ordinary work, carpenters' tools, picks, cold punches, shear blades, slicing tools, slotter tools
490	254	Dark blue	660	349	Hot chisels, tools for hot work, springs
510	265	Light blue	710	376	Springs, screw drivers

It will be noted that two sets of temperatures are shown, one being specified for a time interval of eight minutes and the other for one hour. For the finest work the longer time is preferable, while for ordinary rough work eight minutes is sufficient, after the steel has reached the specified temperature.

The rate of cooling after tempering seems to be immaterial, and the piece can be cooled at any rate, providing that in large pieces it is sufficiently slow to prevent strains.

How are we to know if we have given a piece of steel the very best possible treatment? The best method is by microscopic examination of polished and etched sections, but this requires a certain expense for laboratory equipment and upkeep, which may prevent an ordinary commercial plant from attempting such a refinement. However, I would certainly recommend any firm that has any large amount of heat treatment to do, to install such an equipment, which can be purchased for from $250 to $500. Its intelligent use will save its cost in a very short time.

The other method is by examination of fractures of small test bars. Steel heated to its correct temperatures will show the finest possible grain, whereas underheated steel has not had its grain structure refined sufficiently, and so will not be at its best. On

the other hand, overheated steel will have a coarser structure, depending on the extent of overheating.

To determine the proper quenching temperature of any particular grade of steel it is only necessary to heat pieces to various temperatures not more than 20 deg. cent. (36 deg. fahr.) apart, quench in water, break them, and examine the fractures. The temperature producing the finest grain should be used for annealing and hardening.

Similarly, to determine tempering temperatures, several pieces should be hardened, then tempered to various degrees, and cooled in air. Samples, say six, reheated to temperatures varying by 100 deg. from 300 deg. cent. to 800 deg. cent. will show a considerable range of properties, and the drawing temperature of the piece giving the desired results can be used.

Precautions to be Used in Heat-Treating. The following precautions should be observed in the heat treatment of steel:

1 Do not put a cold piece of steel into a highly heated furnace. Either reheat it or put it into a cold furnace and allow it to heat up with the furnace. This precaution is especially applicable in cold weather. Also remember that the changes occurring in the critical range are not instantaneous. The steel must be given time to change. It does not pay to rush the heating. Raise the temperature slowly.

2 Allow the piece to soak at the quenching temperature until it is uniformly heated throughout, the length of time depending on the size of the piece and the rate of heating.

3 Do not allow the piece to be directly on the hearth of the furnace, but have it supported at a sufficient height to allow a free circulation of gases on all sides. Long pieces should have sufficient support to prevent sagging.

4 Never allow a piece, especially if it has points or sharp corners, to come in contact with flame.

5 In quenching, immerse the piece with the axis vertical. This will prevent excessive warping or cracks due to unequal contraction in cooling.

6 Care should be taken that no sharp grooves, corners or seams are left on pieces to be quenched, which may develop into cracks.

7 In drawing the temper of a large piece in a furnace never put a piece into a furnace hotter than the drawing temperature nor allow the furnace to exceed the required temperature, otherwise the steel will be softer than required.

8 In drawing large pieces, soak a sufficient time at the desired drawing temperature, to allow the heat to affect the center of the piece.

9 In annealing and quenching never depend on the eye to judge the temperature; use a pyrometer.

RESULTS OBTAINED—SANDBERG AIR-COOLING TREATMENT

[In an appendix to his manuscript the author gave details of the results obtained in heat-treating cast-steel billets for large shells to meet the specified requirements of 19 tons yield, 35 to 49 tons ultimate breaking load, and 14 per cent elongation in a 2-in. test piece. For example, a cast-steel blank containing 0.60 per cent carbon and 0.87 manganese was soaked for four hours at 1575 deg. fahr., allowed to cool in the furnace to 1350 deg. fahr., removed from the furnace and cooled quickly to black in air; then reheated to 1275 deg., soaked for $2\frac{1}{2}$ hours and allowed to cool in the furnace. On test this sample showed over 19 tons yield, 46.2 tons ultimate breaking strength, against 51.2 tons theoretical, and 19.5 per cent elongation, which indicates very good annealing.

In a second appendix the author gives details of O. F. A. Sandberg's patented method of blowing air upon hot annealed steel for the purpose of increasing its toughness, elastic limit and ultimate strength over that of normal forged steel, the use of which method was allowed free to manufacturers of forgings for the duration of the war. The method is also to be applied to steel rails to improve their wearing qualities. It involves the distribution of air at $\frac{1}{2}$ to 20 lb. pressure over the pieces being treated to rapidly abstract the heat from the steel. The lower the carbon content, the more rapid should be the cooling.

The beneficial influence of this air blast upon four samples of steel is evidenced by the results given in Table 6.—EDITOR.]

U. S. Shipping Board Rules for the Inspection of Marine Machinery

Standardization work worthy of more than passing mention is that recently accomplished by the United States Shipping Board Emergency Fleet Corporation, the results of which are embodied in a pocket-sized volume it has issued under the title Rules and Instructions for the Inspection of Marine Machinery, Series I. These rules deal respectively with reciprocating steam engines; Diesel engines; steam turbines and reduction gears; water-tube and Scotch marine boilers; direct-acting pumps; condensing apparatus, feedwater heaters, evaporators and distillers; refrigerating machinery; propellers; auxiliary deck equipment such as capstans, winches, towing engines, etc.; and electrical equipment, including d. c. generators and searchlights.

Shortly after embarking on its huge ship-production program the Emergency Fleet Corporation found itself confronted with the imperative need for rational, precise and concordant inspection instructions covering the machinery to be installed in its vessels, not only to facilitate their rapid equipment—which the exigencies of the times demanded, but to insure that reliable machinery making for safety at sea, conforming with existing maritime regulations and whose standard parts were of interchangeable construction, would be produced.

The task of formulating such rules was accordingly placed late last fall in the hands of John A. Stevens, Standardization Engineer of the Fleet Corporation, a Vice-President of The American Society of Mechanical Engineers and Chairman of its Boiler Code Committee. Mr. Stevens at once summoned to Philadelphia some sixty of the country's prominent engineers—selected for their expert knowledge of the practical allowances, clearances, tolerances and materials that were to be provided for in the proposed instructions, and these in conjunction with the departmental engineers and chiefs of the Fleet Corporation, under his effective direction, succeeded after a few short weeks of unremitting endeavor in accomplishing the desired result. Twenty-eight of those coöperating in this important work are members of The American Society of Mechanical Engineers.

It is stated in the introductory remarks that the rules and instructions as published are not retroactive in nature and are not to be applied to machinery which has been constructed, inspected and stored; and that the whole intent of the work is to provide reasonable, sensible and commercial inspection on machinery now building or which may be built in the future.

The total number of merchant vessels under construction throughout the world (excluding the Central Powers) on December 31, 1918, according to Lloyd's Register Shipbuilding Returns, was 2189 ships of 6,921,989 gross tons, or double the largest corresponding tonnage under construction before the war.

Electric Furnaces as Applied to Steel Making

By HENRY LAWRENCE HESS,[1] BALTIMORE, MD.

THE war has wrought many remarkable changes, and when details are fully published, I believe it will be found that the electric furnace and the electric-steel industry have given a decidedly satisfactory account of themselves.

The war has undoubtedly aided the phenomenal growth of the electric furnace, but this growth has to a large extent been the result of the demand of the steel user for a quality product. The ultimate consumer in a large measure is the court of last appeal. It is the ultimate consumer who realizes that the best materials are none too good, and, taking into account the comparative cost of the steel, the cost of labor put upon it, and the tools used in fabricating, decides that it is economy to use the best steel, and that electric steel meets his requirements uniformly and satisfactorily, thus producing a demand resulting in its rapid growth.

In 1910 there were in operation in the world 114 electric furnaces. Most of these were small experimental units. In 1913 there were 140 in use. In the United States there were in operation in 1913 only 19 furnaces. In 1914, just before the war broke out, there were 213. Since then, of course, we have no reliable information as to the number of furnaces operating in Europe, but in January, 1918, there were in the United States alone, 233, 126 of which were of the Héroult type. An *Iron Age* estimate of the total furnaces in the world at the beginning of 1918, is 733. This is an expansion of over five times in four and a half years, which is truly a remarkable showing. Since January additional furnaces have been installed, bringing the total up to 265 units for the United States.

The probable tonnage of electric-furnace steel for the world is about 4,000,000 tons per year, with the United States and Canada contributing a little less than one-half of this, or about 1,800,000 tons.

Two Methods of Producing Electric Steel

In speaking of electric-furnace steel for forgings or rolling, we must bear in mind that there are two distinct types of this steel, or rather two distinct methods of producing electric steel. One is the duplex method, where molten steel, partly refined in the open hearth, is taken from this latter furnace and charged in the electric furnace for finish refining. The other is the cold-melt method where the raw materials are charged cold into the electric furnace and the entire process of melting and refining is done in that furnace. Naturally there are advocates for both methods. One manufacturer using the duplex method has referred to the cold-melt method as the complex way of making electric steel. All cold-melt makers will naturally disagree with this alleged complexity of manufacture.

The refining period is the critical period in the electric-furnace cycle and this is naturally present in both the duplex and the cold-melt methods. Any multiplication of operations adds to the possibility of added difficulties. Pre-melting in the open hearth, entails two types of equipment and specialists for both. Given competent supervision of the electric furnaces and experience in their operation, the cold-melt method appears to be the far more simple of the two. There is no comparison between the ease of control and the adaptability of the electric furnace to metallurgical manipulation and those features of the open hearth. Suffice it to say that the electric furnace is the most advanced medium for the manufacture of steel that can be placed in the hands of the metallurgist or steel manufacturer. The cold-melt method is particularly adapted to small units. Where the furnace capacity runs above 10 tons, difficulties are encountered in satisfactory melting, although furnaces of this character have been built.

Many concerns using the duplex method have done so since the electric furnace has come as a natural addition to their plants which originally contained open-hearth furnaces. A very important factor in favor of duplex electric steel is its lower cost of production. Electric power is not cheap, and melting by electricity means high conversion cost. Melting in the open hearth and refining in the electric furnace gives good steel, when handled correctly, at lower cost. There is always the possibility, however, and sometimes the tendency, to decrease the electric refining period, and the costs, and to put on the market an electrically washed steel in price competition with true electric steel. A discussion as to the metallurgical superiority of well-made steel of either class is a lengthy although interesting one, and much can be said on either side, although it is fairly agreed that the advantage of ultimate quality rests with the cold-melt method.

The Héroult Type of Furnace, Old and New

The plant that I am interested in operates two 6-ton and four 7-ton Héroult furnaces. These furnaces were chosen because there is a far greater number of them in operation in this country than of any other type, and it is, therefore, easier to obtain men familiar with the operation of the Héroult furnace. Even so, it has been decidedly difficult during the last few years to educate men in the operation of electric furnaces fast enough to keep pace with increased installations.

The 6-ton furnaces and the 7-ton units are very similar as to electrical equipment and operation. The most pronounced mechanical difference is in the method of tilting when pouring. The older 6-ton furnaces have a rounded bottom to which are attached heavy cast-steel semi-circular racks that roll forward on a horizontal rack attached to the foundation, the tilting being done by an electric motor through a series of gears, pinions and tilting arms. Tilting in this way throws the spout and the stream of metal forward as the angle of tilt increases, making necessary the following of this stream by the ladle. To eliminate this feature, the new furnaces are pivoted on trunnions, the center line of which is directly under the pouring spout. As this furnace thus tilts around the spout, the stream remains constant and it is not necessary to move the ladle during the entire pouring of the heat. The weight being carried well forward in this design, necessitates the provision of counterbalance weights to make possible the use of a small tilting motor and eliminating the likelihood of a sudden dropping back of the furnace due to shearing of a key in the tilting mechanism or other cause.

The power comes to us as 25-cycle, 3-phase, 13,200-volt current. In our stations we transform this down to 100 to 110 volts for use in the furnaces. The 6-ton furnaces are rated at 1200 kva. and the 7-ton at 1500. The power consumption runs from 650 to 900 kw. per ton, depending upon the type of steel being melted and the degree of refining necessary.

In using the electric furnace for casting purposes, acid linings are sometimes employed; but when used for the production of ingots which are later to be turned into tool or alloy steels it is almost universal practice to line electric furnaces to somewhat above the slag line, with a basic lining. Magnesite brick is used for the walls and partially for the bottom; magnesite, magdolite, dolomite, syndolag, etc., being used for bottom making and patching, according to the individual preference of the manufacturers.

The Cold-Melt Method of Producing Electric Steel

The raw materials in the cold-melt process are charged into the furnace, the electrodes being raised to permit the loading of a full charge. The doors are then closed, the hand control drawn into operation, and the electrodes, which in the 6-ton and 7-ton size Héroult furnaces are usually made of carbon and are 17 in. in diameter, are gradually fed down until contact is made with the charge. Naturally as contact is first made with the scrap and as the interstices between this material vary and change as the melting takes place, there are rapid fluctuations of power input. These power fluctuations are individual to each phase, and it is because of this very rapid change of load and the practical im-

[1] Vice President, the Hess Steel Corporation, Jun. Am.Soc.M.E.

possibility of taking care of this mechanically, that the hand operation is often used, which operation is not as rapid as the mechanical.

As the charge begins to melt, and when the power load has settled down somewhat, the switch is thrown on to the mechanical control. This control operates through a series of switches connected to a control apparatus, which throws the power into the direct-current motors which are directly attached through a series of gears to drums which raise or lower the electrodes, decreasing or increasing the power input.

Control of temperatures and knowledge as to the temperature to be used during melting and refining is of prime importance.

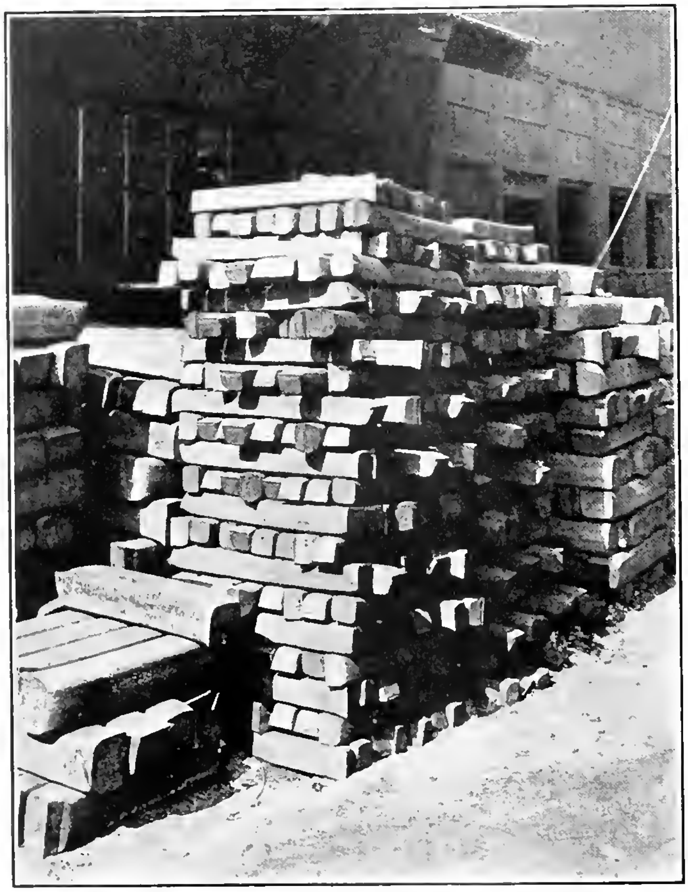

Fig. 1 Electric Steel Billets, Each Having Identification Marks

The pouring temperature must be right, for if the metal is too cold a heavy scull will be left in the ladle; if too hot, the possibility of ingot surface troubles is present, coupled with a greater likelihood of segregation.

The initial melting is done under as high power input as is possible, bearing in mind the necessity of obtaining from the furnace walls and roof the longest life economically possible when compared with the output.

Later, after the metal is melted, metallurgical reasons necessitate close control, and the temperature has quite a little to do with the removing of impurities from the steel. During the melting down, the raw materials charged have given up impurities of various sorts which are held in suspension in the molten metal. These impurities may be oxides, silicides, silicates, etc., which do not alloy with the steel but remain distinctly separate from the metal. If the molten steel were as transparent as water in a glass, we could see these foreign inclusions floating in the bath very much like small particles of dust. They are too small to rise to the surface of the bath in a short time, although their specific weight is lower than that of the steel. If, however, they could agglomerate and run together as mercury does and form large globules, then they would rise much more quickly to the surface on account of the greater buoyancy of their larger volume and would leave behind a cleaner steel. The melting temperature of most of these admixtures, however, is much higher than that of the steel, which means that they are still solid when the steel has reached a temperature sufficiently high for tapping.

In order to make the foreign inclusions coalesce and so form larger globules which will more readily free themselves, it is necessary, if possible, to liquefy them, which means a superheating of the metal. Such superheating also enables the deoxidizing agents, such as silicon, manganese, etc., to act more effectively and to make the deoxidation of the bath more complete than would be the case if the metal were more or less sluggish, or viscous. It is very necessary, however, that care be taken in this superheating, as the electric arc is the hottest-known source of heat and there is a grave possibility of burning the steel, as well as the aforementioned shortening of life of linings and roof.

Refining and slag building require that high temperatures be used, and as a rule the power is shut off entirely a few minutes before pouring in order that the bath may have a chance of settling and relieving itself of any particles of slag which may have been stirred into it.

As the melting continues, the operation becomes smoother until finally with a completely molten bath, the input of power is practically constant and is regulated according to the temperature required by the melter, to suit the stages of the refining operation. The total power input, as mentioned above, varies from 650 to 900 kw. per ton.

The charge depends upon the type of material to be made. For certain tool steels and highest-quality products it has been found best to use wash metal and ingot iron as a base. This material necessitates very little refining. For ordinary materials, because of the ease of refining in the electric furnace, it is possible to use a greater variety of raw stock. Heavy melting scrap bought on analysis limitations is used as a rule. With this charge of scrap a certain amount of limestone is added, which, upon fluxing with the molten metal, forms the basis for the slag. Through its reactions and affinities the impurities contained in the bath are eliminated to a large extent, especially phosphorus, which it is desired to reduce from the metallic charge. The character of the slag is altered to suit the reaction desired. After the action of the first slag is completed, it is removed and a second added.

During the various stages of the melting-down and refining periods, the metallic additions are made to bring the steel to the final analysis. These additions comprise, for instance, ferromanganese and ferro-silicon, which are used as deoxidizers, as well as for alloying, ferro-chrome, nickel, vanadium, tungsten, etc., etc. In addition to these ferro-titanium is sometimes used, and where deoxidization is not complete, it is sometimes customary to use a small amount of aluminum; this latter, however, is not considered best practice.

Building Up Correct Slags

The building up of correct slags is quite an art and is one of the most important factors in the making of a successful electric-furnace steel. Practice varies in this to some extent. Certain concerns prefer limestone; others use slacked lime. Preference lies with some for a more liquid slag than others think best, which means a variation in the use of sand and fluorspar. A ground coke is used in the formation of the white slag, the reason being that it attacks the calcium oxide (CaO) and forms metallic calcium which in turn splits sulphides of iron and manganese (FeS and MnS) forming calcium sulphide and metallic iron or manganese (CaS and Fe or Mn). The surplus of calcium combines with the surplus carbon and forms calcium carbide—a sure sign that active desulphurizing conditions are present in the furnace. The older opinion that calcium carbide is the active agent in desulphurizing, does not hold good in actual operation, and formerly calcium carbide was added for desulphurization, neglecting the fact that calcium carbide in itself is not active in desulphurization, depending, as it does, upon its first splitting for its action.

Naturally of prime importance is the selection of the raw materials and alloys entering into the metal and the correct calculation of the weights of these, etc., but too much consideration cannot be laid upon the necessity of careful manipulation and an ex-

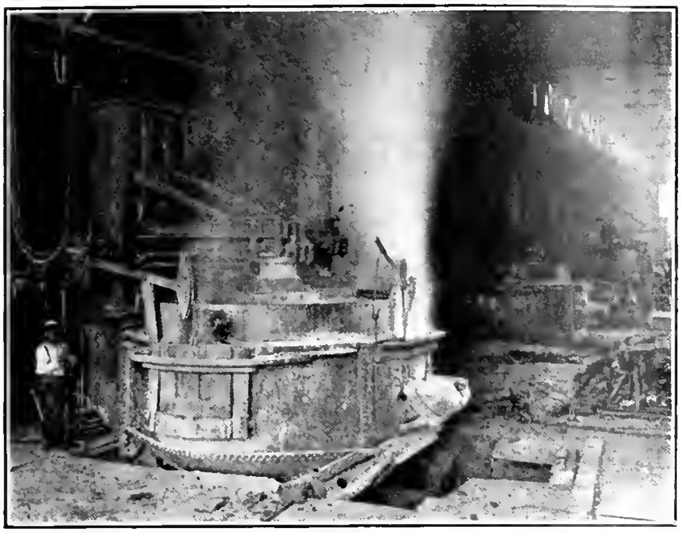

Fig. 2 Electric Furnace in Operation

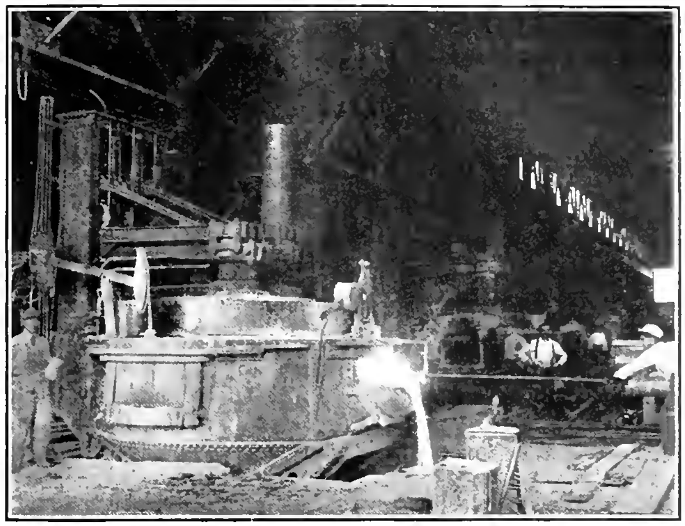

Fig. 3 Skimming Slag from Electric Furnace

perienced judgment in controlling the materials charged in the furnace during their melting and refining periods. The charge must be melted as rapidly as possible. Some concerns in melting down place great importance upon the necessity of not burning out the carbon below a point of approximately 0.20 content. The manganese will then, if everything has been operated carefully, be approximately around 0.30. Other concerns permit the carbon to be practically entirely reduced, a content of 0.04 or 0.05 being quite usual. It is somewhat more difficult to control the carbon and prevent this being entirely removed, but if such reduction of carbon and manganese is prevented, there is evidence that the bath has not been in an overoxidized condition, which may have been the case when the carbon has been completely removed. It should be borne in mind that when an undue amount of overoxidation has been once introduced into the molten metal, that it is practically impossible to thoroughly deoxidize the steel again with any degree of certainty. Even with the greatest care in the deoxidizing, there will always remain metallic oxides of one form or another, practically impossible to remove, and which exert a deleterious influence upon the metal produced. Fast melting with a careful supervision of the power input, proves advantageous in connection with the above practice of holding the carbon and manganese.

Heating in the Héroult Furnace

In some types of electric furnaces, the metal is subjected to heating not only from the top but from the hearth as well. In the Héroult all the heating is done from above by means of the electrodes near and above the center of the bath. This means that the heat is applied more or less locally and that there is very little tendency for circulation of the metal. In other words, the molten metal lies practically dead on the hearth. This is particularly true of that portion of the metal lying near the bottom, and for this reason, the heavier alloys have a tendency to settle, causing lack of homogeneity of the product and segregation of certain elements. This fact must be taken into account in the operation of the furnace and the metal must be put in circulation by means of systematic and vigorous stirring.

Pouring from the Furnace

In tapping the metal from the furnace, great care must be taken to see that there is as little opportunity as possible for the slag again to become mixed with the metal, and that opportunity also be given for any slag that has become mechanically mixed with the steel to rise from the metal. This is done by holding the steel in the ladle after it has been poured for as long as may be, without bringing the metal down to a temperature below that which is safe for pouring.

In ingot work practically all of the steel made is poured from "bottom-pour" ladles. Some pour directly from such ladles into the mold, others use intermediary measures such as boxes which break the head and give a more uniform and less violent stream, which tends to improve the ingot surfaces and prevent surface defects in the rolled billets and bars. Both of these methods are termed "top pouring."

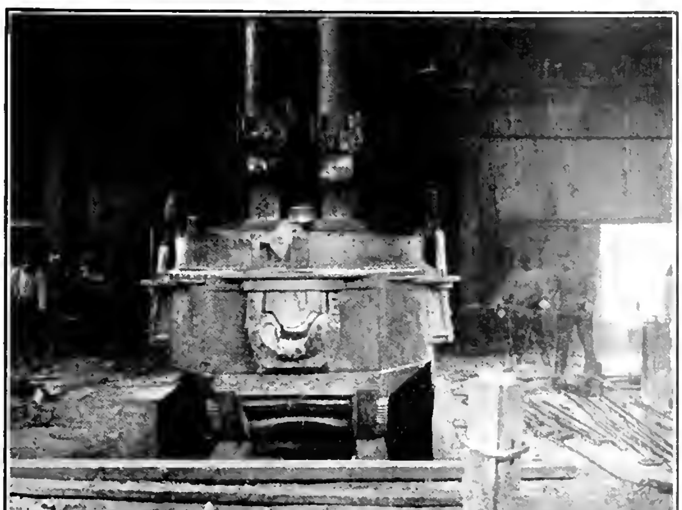

Fig. 4 Charging

Fig. 5 Stripping, Showing Refractory Top Brick

Another method is to pour down a central runner which divides at the bottom into feeders very much like the fingers of a hand, which in turn lead the metal to the bottom inlet of the ingot molds, so that as the steel is poured down the central runner, the metal rises uniformly in a set-up of molds, which usually take an entire heat.

In cooling there is a contraction of the molten metal in the molds. This contraction develops, upon solidification, along the axis of the ingot, a central cavity, largest at the top of the ingot. By carefully designing ingot molds, this tendency can be checked to some extent, and where the saving in croppage warrants such expense, as is the case with alloy and tool steels, a heat-retaining form is set upon the top of the mold, which by preventing radiation of the heat, keeps the enclosed metal hot, which metal then feeds the cavity or pipe as it develops in the ingot proper. These refractory forms are sometimes rammed up of molding sand at the plant, or are of a specially prepared fireclay material particularly adapted to this work. This latter type of hot-top brick is considered decidedly good practice, as with the use of such brick, there is practically no added possibility of introducing dirt into the steel, as is very often the case when the molded sand hot tops are used, since the faces of these sometimes spall off when subjected to the intense heat of the stream of molten metal passing by them.

Rolling

After cooling, the ingots are removed from the molds, commonly called stripping, inspected and sent forward for further working, which may consist of forging or rolling. This paper will deal with rolling only.

Some grades of steel require special precautions, such as slow pit cooling to prevent surface cracking; or annealing to relieve internal strains and prevent checking, and for the improvement of the ingot structure. This annealing is preferably done before the ingots cool down materially.

In tonnage plants, operating on steels for rails, plates, structural shapes, etc., the ingots are charged hot as quickly as possible after pouring, into soaking pits for heating, and are then rolled or forged, as much of the initial pouring heat being retained as is feasible.

Each ingot naturally bears its identification number, which number is carried along to the final product, so that it is possible to check the bar or rod back to the heat where it was made in order that the causes of any defects may be traced.

In most alloy mills the ingots after being delivered to the rolling mill are charged into a heating furnace where they are brought up to the temperature necessary for rolling. This temperature varies according to the analysis of the material to be rolled and must be uniform throughout the ingot. If the ingot is unevenly heated, trouble will be encountered in the rolling. If very cold, the rolls may break due to their inability to stand up against the enormous strain put upon them in attempting to reduce the cold metal. If heated unequally, one side being hot and the other cold, it will be difficult to control the material in rolling, as the hot side will naturally elongate more easily than the colder and the bloom will warp and cause trouble in passing through the guides, and sometimes make it impracticable to follow through the series of passes to final reduction.

Often an ingot will look as though it were heated to the correct temperature, but the period allowed for heating may have been too short, and the core, or the center of the steel, be still cold. This will also give considerable trouble as there will be a differential flow between the outer hot layers of the material and the colder core.

It is impossible to go into great detail here as to the various processes and methods of rolling, the power required, etc., but the equipment used by the company with which I am connected may serve as an indication.

This concern has adopted as its standard for alloy and tool steels, 9-in. by 9-in. ingots weighing approximately 850 lb. This ingot is heated up in a continuous heating furnace, equipped with an electric pusher, which furnace feeds a 20-in. mill having two three-high roughing stands and one two-high finishing stand. It is driven by a 600-hp. Westinghouse motor with Westinghouse slip-type regulators, driving through a series of herringbone gears, which reduce the speed of rotation to a mill speed of 62 r.p.m.

The bar capacity of the mill is from the 9-in. ingot down through a series of Gothics, squares and diamonds, to rounds and squares 2 in. in diameter. The standard billets produced for re-rolling are 4 in. These smaller billets after being rolled, are carefully inspected for surface checking, etc., pickled, chipped, reheated in another heating furnace and rolled down into the size desired on a five-stand 9-in. mill capable of giving all sizes from $1\frac{7}{8}$ in. to $\frac{3}{8}$ in. round or square. The hp. required on this smaller mill is 400. The same type of slip regulator is used for speed regulation, but, as on the smaller work, it is necessary to have some variation in speed control of the mill, and as this is not easily possible with alternating current, a heavy two-speed gear change is provided, which enables the mill to roll at 120 or 240 r.p.m.

After the bars are finish rolled, they are cut to length, inspected, straightened and shipped as finished bars, or are annealed for the refining of their grain and the softening of their structure, or heat-treated to obtain special physical characteristics.

These latter phases of the steel industry are by far the most interesting of the entire business, and most remarkable results can be obtained due to modern laboratory control and micrographical examination.

German Substitute Materials

Prior to the war by far the greater portion of raw stuffs required by Germany were imported from abroad (in round figures valued at about 10,000,000,000 marks). The blockade practically shut out foreign imports. It is thus natural that the question of substitute materials became the absorbing one in Germany. Official, industrial, and scientific Germany applied its utmost energy in attempting to solve it.

The principal efforts were made in the fiber and thread industry. The most interesting inventions in the field of textile substitutes are those procured from burning nettles, and it is believed that a valuable substitute for cotton has been found. A new chemical process for the extraction of the glutinous matter of the plant fiber has been developed and great progress has been made in extending the cultivation of burning nettles, which have been planted in great quantities.

Peat fiber belongs to the most interesting discoveries in the field of substitute textile raw stuffs. This can not, however, be practically used without mixture with other kinds of fiber. A mixture of 50 per cent peat fiber and 50 per cent wool gives what is said to be a strong and durable material that looks well and is satisfactory for men's clothing. The valuable qualities of peat fiber, however, are limited by the difficulties in procuring the peat. Only the younger moss turf can be employed in spinning. The black peat (used for burning) cannot be employed. The production from about 500,000 tons of peat amounts to about 10,000 tons of fiber; in other words, a very small amount, when the labor as well as the actual yield are both taken into account.

Great efforts have been expended, also, in attempting to find substitutes for leather and rubber.

The textile company "Barken" has succeeded in finding a substitute for "uppers," which promises to prove valuable even in peace times. Artificial rubber was produced prior to the war, but was shortly given up owing to the fact that cultivated rubber fell in price from 30 to 4 marks per kilo. When the scarcity of rubber again arose with the war, the production of synthetic rubber was again considered. Substitutes, however, had to be discovered owing to the lack of acetone and aluminum. When it was found possible to produce acetone from coal and carbide and to produce aluminum on a large scale (principally by "Grisheimer-Electron"), the production of artificial rubber could be undertaken. But the synthetic rubber is evidently merely fitted to meet a war need, for it cannot compete with the genuine article. Added to this its cost is much higher than London quotations for genuine rubber. (*Commerce Reports*, Jan. 18, 1919.)

LIBERTY ENGINE TESTS

Authentic Data on Performance Tests of the Standard High-Compression Army-Type 12-Cylinder Liberty Engine

Since the signing of the armistice a considerable amount of information has been published as to the design of the Liberty engine and its accessories. It is believed, however, that this is the first time that complete information as to the performance of the Liberty engine of the standard high-compression Army type has been published in a general engineering periodical. This information is of special interest as it shows the great power developed by this type of engine.

THE Liberty engine represents a typically American design from several points of view. The fundamental problem in developing this motor was to produce a unit which could be manufactured in quantity with such labor as was available in this country. Of course, there were at least as many skilled workmen in America as in Europe, but every skilled man was immensely necessary in a position where only skilled labor could be employed, such as tool making, ordnance production, etc., and the vast demands for aircraft motors could not be satisfied with skilled labor without disorganizing other equally important fields of production of war material.

If aircraft engines were to be built in sufficient quantities (and the original idea was to supply motors not only to America but also to the Allied forces) such motors had to be designed in such a manner as to be produced, as far as possible, by automatic machinery. This problem is actually far more difficult than would appear at first sight, because an aircraft motor has to combine unusual endurance qualifications together with light weight.

Figs. 1 to 4 show the general design of the Liberty engine. Its peculiar characteristics were such a development of parts that practically all parts could be produced on machinery of the type previously employed for mass production of automobiles.

The crankshaft is of the conventional type with seven bearings, but without counterweights. The pistons are of the die-cast aluminum-alloy type with very thick heads and tapered, increasing in thickness toward the top; a floating-type piston pin is employed. The assembly was based on the use of the individual cylinder design with steel cylinders made by a process developed by the Ford Company.

Data of several tests covering various phases of performance of Liberty engines of the standard high-compression Army type have been published in recent issues of the Bulletin[1] of the Experimental Department, Airplane Engineering Division, Bureau of Aircraft Production, War Department, from which the following abstract has been prepared by special permission.

A heat-balance test on a standard high-compression Army-type 12-cylinder Liberty engine was carried out at McCook Field, Dayton, Ohio. In this test the engine was run at a constant speed of 1600 r.p.m. with wide-open throttle, developing under these conditions an average horsepower of 372.5, the tests being continued for one hour under constant conditions. These conditions involved a water-outlet temperature of 170 deg. fahr., a water-inlet temperature of 150 deg. fahr., a carburetor setting choke 36, jet 160, compensator 165 and an average speed of 1600 r.p.m.

Pennsylvania gasoline of 68 deg. Baumé gravity was used, with an average consumption of 0.492 lb. per hp-hr. The average amount of jacket water pumped per minute was 90 gal., or, roughly, 720 lb.

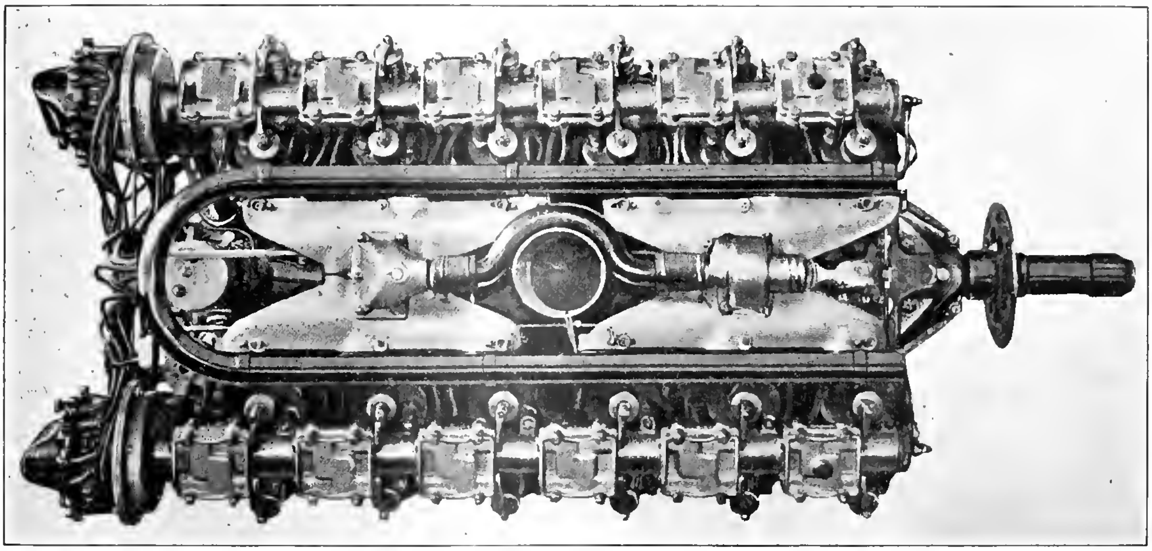

Fig. 1 Top View of Liberty Engine

Based on 19,000 B.t.u. per lb. of gasoline at 100 per cent efficiency, 183 lb. of gasoline per hour will give theoretically 1365 hp., which was distributed as shown in Table 1.

TABLE 1 HEAT BALANCE OF STANDARD LIBERTY "12" ENGINE

	Hp.	Per cent of B.hp.	Per cent of total
Average brake horsepower	372	100	27.3
Average heat absorbed by jacket water	339	91	24.8
Average frictional horsepower	48	13	3.5
Remaining heat units carried off by exhaust	606	163	44.4
Total—Theoretical horsepower	1365		100.0

This table indicates that 27.3 per cent of the theoretical horsepower was converted into power by the engine, which shows a high efficiency of the water plant, especially considering the high heat losses at the exhaust. (Bulletin, June 1918, p. 77.)

A still more important test is reported in the Bulletin for July 1918. In this instance twelve engines of the standard model-A production were given identical tests in the McCook Field dynamometer laboratory, after which they were torn down and carefully inspected.

The engines were given a complete run with the standard production setting of the Zenith carburetors of 31 choke, 140 jet and 150 compensator, as well as a test with setting of 36 choke,

[1] Bulletin of the Experimental Department, Airplane Engineering Division, U. S. A., McCook Field, Dayton, Ohio, June, July and August, 1918.

165 jet and 170 compensator to determine the influence of the carburetor adjustment on the average results.

In this connection it may be stated that it has been found that the latter setting is much better than the former to such an extent that at 1800 r.p.m. with wide-open throttle the average difference in power varies in the favor of the former setting from 30 to 34 hp., the gasoline consumption being also in favor of the first setting.

Tables 2 and 3 give, respectively, the average power data and the average gasoline and oil consumption obtained from six of the twelve engines (made by the Packard Motor Car Company, of Detroit, Mich.). These data show that the engines developed power curves, of which Fig. 5 is here reproduced as representative of the set. It is also of interest as bearing out the data of Tables 2 and 3. (Bulletin, July 1918, pp. 86-104.)

A series of highly interesting tests was carried out at the laboratories of McCook Field with a special single-cylinder Liberty engine built for test purposes only. Tests carried out with this engine covered such elements of engine design and construction as pistons, piston rings, valve construction and timing, cam design, ignition timing, cylinder lubrication, spark-plug tests, etc. In such tests a single-cylinder engine is as good and sometimes better than one of the multi-cylinder type, not only because it is cheaper and easier to handle but because it affords better

on an average from about 275 hp. at 1200 r.p.m. to 412 hp. at 1800 r.p.m., which is a very good output considering the weight of the engine.

Spark plugs gave considerable trouble throughout the test. It was noted that this trouble would diminish greatly as the test proceeded, showing that a certain number of plugs will fail after a very short time in service, frequently as little as 5 min. This generally was noted by the porcelain chipping off at the outside of the plug, thereby allowing the plug to jump from the center electrode to the outside shell. There is evidently a strain set up in the manufacture of some of these plugs, so that they are unable to withstand the heat or vibration of the engine for an appreciable time.

A suggestion is made in the report that consideration be given to some method of subjecting the plugs to an operating test at the manufacturer's plant which will in some way simulate actual operating conditions, thus enabling the manufacturer to eliminate those plugs which now give service only for a few minutes. At the same time it should be borne in mind that dynamometer testing conditions are somewhat more severe on spark plugs than are actual flying conditions.

Curves for fuel and oil economy are given as well as average facilities for detecting slight variations in the character of operation.

For these tests a special engine was constructed, in reality a standard Liberty engine of one cylinder instead of twelve: the cylinder itself, valves, valve springs, piston, piston pin and rings, etc., being exactly the same as those used in the 12-cylinder engine, while the crankcase, crankshaft and camshaft were different. Care was taken to arrange the installation in such a manner that the design of the engine would not differ from that of the 12-cylinder engine to such an extent that it might affect the results. For all tests a special carburetor was used—diagrammatically shown in the original article. The ignition for this engine was identical with that of the Liberty-12, a special timing mechanism being used.

Data of tests are summarized in a table, each test covering one or more variables as the case may be. It might be stated, in this connection, that the tests made with the single-cylinder engine to obtain data for the improvement of the design of the 12-cylinder unit are of particular interest as a good lesson on methods in engine designing. While not every plant can afford such a thorough investigation of its products, it is certainly an excellent way to secure extremely valuable results wherever it can be done.

The tests have brought out several factors of considerable importance. The first variable which was tested was that of the employment of a horizontal intake pipe that was not water-jacketed. Five series of tests were run; the first without any intake pipe at all; then with different lengths of pipe, such as 6-in., 10-in., 14-in., and 18-in. It was found that the results were materially affected by the carburetor choke size and were non-uniform for different speeds. Thus, with $1\frac{1}{8}$ in. choke, the highest horsepower with the 14-in. intake was obtained at 1600 r.p.m., equaling that with the 10-in. manifold pipe at 2000 r.p.m. With the same choke and an 18-in. intake pipe the highest output was secured at 1600 r.p.m. (29.6 b.hp.), but at 2000 r.p.m. this fell to 26.8 b.hp., which would indicate that with the increased suction there was a throttling action at the choke or increased turbulence in the intake pipe. This agrees well with the third set tests with $1\frac{5}{8}$ in. choke, where the brake horsepower increased fairly uniformly with the engine speed in all cases and did not appear to be materially affected by the difference in length of intake from 14 to 18 in., though with the short intake, 10 in., it was slightly lower (41.0 b.hp. as against 42.0 and 42.8, respectively).

At first the improvement realized with the 18-in. intake pipe, which size proved superior to any of the others, was ascribed solely to the "battering-ram" characteristics acquired by the column of mixture in the intake header. The particles, having some inertia, tend to build up a pressure against the carbureter side of the inlet valve while the valve is closed, which pressure is available on the next suction stroke to assist in forcing in the new charge. That there is considerable pressure generated in this manner is proven by the fact that the gasoline vapor is blown back out of the carbureter choke when the engine is running. Later experiments proved, however, that the battering-ram feature plays a minor part in the success of the long intake header. Tests made later with a water-jacketed manifold to the same length proved that it was the reduction of temperature in the long intake pipe which accounted for most of the improvement in the tests which were run without any water jacket around the intake header. It was found that the mixture when not heated in the intake pipe reaches a minimum temperature of about 40 deg. fahr. below the carbureter intake air temperature.

Fig. 7 shows the 18-in. horizontal intake manifold fitted with a water jacket so that all the cooling water passing through the cylinder jacket also passes through the water jacket around the intake header after leaving the cylinder. The curves in Fig. 9 show the effect on the horsepower output of the use of this water-jacketed intake, and also the resulting increase in temperature of the gases in the intake manifold. The engine outlet water temperature was controlled and power readings were taken over a range of various temperatures of the cooling water from 90 deg. to 200 deg. fahr. at a constant engine speed. The drop in power with the increase in water temperature, which, of course, increased the temperature of the gases in the inlet manifold, was plotted together with the actual changes in the inlet gas temperatures.

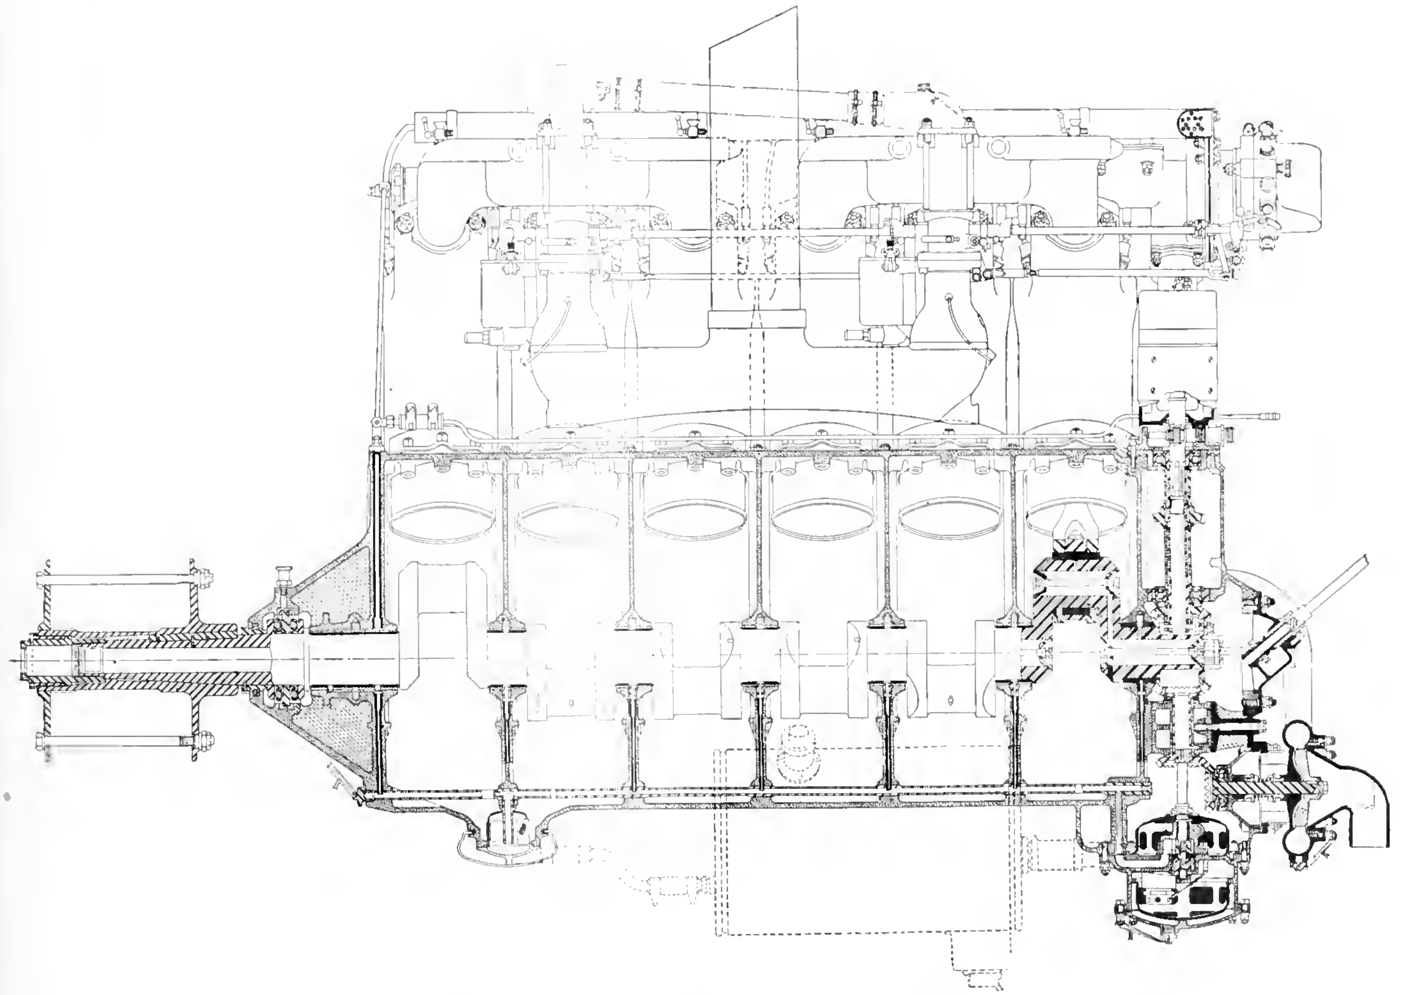

Fig. 2 Longitudinal Section of Liberty Engine

The curves in Fig. 8 prove conclusively that the power output is largely increased with the cold manifold, and show that this is one of the simplest means of obtaining supercharge. The amount of supercharge may be easily as high as 10 per cent, figuring an increase of volume of 0.2 per cent for each 1 deg. fahr., based on 100 per cent volume at 32 deg. fahr. In other words, with the temperature in the inlet pipe at 32 deg. fahr., 10 per cent more mixture can be had at atmospheric pressure than if the temperature in the intake pipe were 82 deg. fahr.

It is believed that certain difficulties will arise if the intake temperatures are lowered too much. It is reasonable to suppose

that the distribution of a uniform mixture to the various cylinders will become more and more difficult as the temperatures are lowered, due to the heavy particles of fuel carried along in a liquid state having considerable inertia. No doubt there would be a tendency for these particles to accumulate in larger percentages in those cylinders which from the nature of the manifold are reached by an easier or straighter path from the carbureter.

It would seem that the so-called "hot-spot" manifold would furnish a solution of this difficulty. This type is so designed that only a portion of it is heated, that being the section in which the liquid particles carried along by the gas are most likely to come in contact with the inner walls of the manifold.

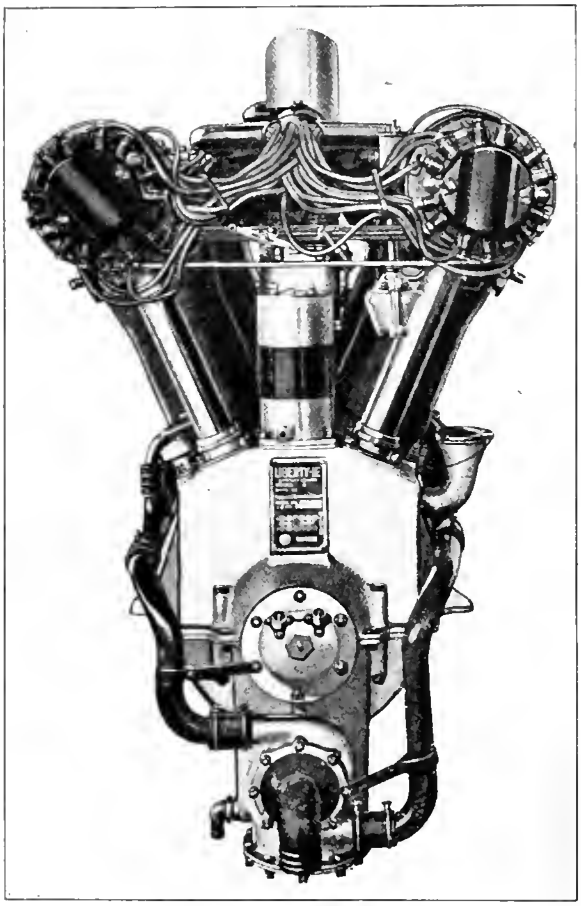

FIG. 3 DISTRIBUTOR END OF LIBERTY ENGINE

It is noteworthy that both the Mercedes and the Benz engines have long manifolds which are covered with an insulating wrapping. Recent tests of a 260-hp. Mercedes so equipped have shown perfect distribution of the intake gases, proving that by proper design of the intake manifold distribution difficulties with cold mixtures can be practically eliminated.

The question of fuel economy also comes up in this connection, although this evidently is largely a matter of distribution. There are indications, however, that a slight sacrifice of economy may accompany a large increase of power, due to cold intake gases.

Obviously there is little or no likelihood of using a straight 18-in. horizontal intake pipe on a V-type engine such as the Liberty-12. In order, therefore, to simulate as much as possible the construction form which would exist in such an engine, a crooked vertical intake pipe was made up as shown in Fig. 6.

The results of numerous tests with the crooked intake pipe prove that its action is on the average quite similar to that of the straight pipe. Comparisons of tests 8 with 16, 20 with 13, 12 with 15, and 24 with 36 (see Table 1, August Bulletin) show that in one case one pipe is somewhat superior and in another case the other pipe is slightly better. It is apparent, therefore, that the cooling action of the one pipe is about the same as the other, and whatever difference there may be in the battering-ram action between the two pipes does not materially affect the result.

There was very little spark-plug trouble throughout the single-cylinder engine tests, which would seem to indicate that the raising of the brake mean effective pressure in the 12-cylinder Liberty engine will not necessarily bring about an increase in spark-plug defects.

With the best combination of features on the single-cylinder engine it was found that at 1800 r.p.m. it developed 39 hp. Multiplying this by 12 would give 468 hp. for a similarly fitted 12-cylinder engine. Theoretically, the power output of the 12-cylinder engine should be about 25 hp. more than this, due to the fact that the friction losses of the 12-cylinder engine would not be 12 times as great as in the single-cylinder engine.

From results of these tests it would appear that a 12-cylinder engine can be advantageously fitted with pistons of a 6 : 1 compression ratio. Such a compression ratio in combination with the other features appeared also desirable, as it was believed that it would give a greater ceiling for the plane and greater speed at high altitudes. These tests further indicated that it might become desirable to use a reduction gear between the engine and propeller, thus enabling the engine to develop its greatest power at the highest practicable running speed while still utilizing more efficient propeller design. This has been ultimately adapted with the so-called Liberty epicyclic reduction gear.

The next tests were designed to determine the results of operating two production motors in the air for long periods without overhauling. In this instance two standard-production Liberty engines were given flight tests under service conditions as nearly as possible. One of the test engines (801) originally ran 60 hr. and the other (719) was operated 75 hr. Both were then torn down for examination, when it was found that they were in such excellent condition that it was decided to reassemble them without any replacements of parts and give them a much longer test. The first engine was run an additional period of 100 hr. and the other 85 hr., making a total of 160 hr. for each.

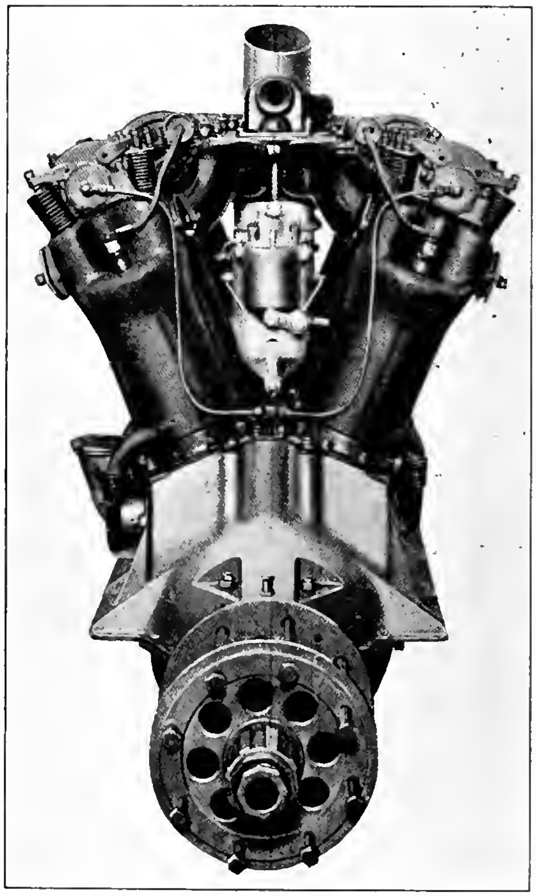

FIG. 4 PROPELLER END OF LIBERTY ENGINE

When these engines were torn down after the 160-hr. runs they were still in fairly good running condition, neither having shown

any signs of imminent failure. On the other hand, it was apparent that neither engine would have run very much longer.

In all these tests the engines were mounted in Curtiss R-4 planes, which are somewhat slower and heavier than the DeHaviland-4, but similar enough to the DeHaviland to warrant the belief that both the horsepower developed and the fuel consumed

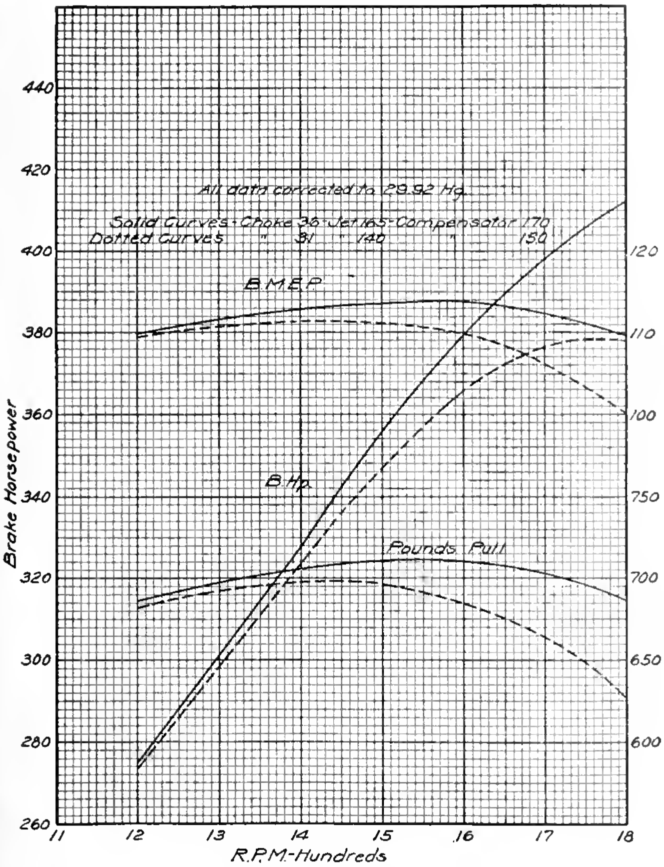

FIG. 5 CURVES OF FUEL AND OIL ECONOMY AND OF AVERAGE POWER OF LIBERTY ENGINE

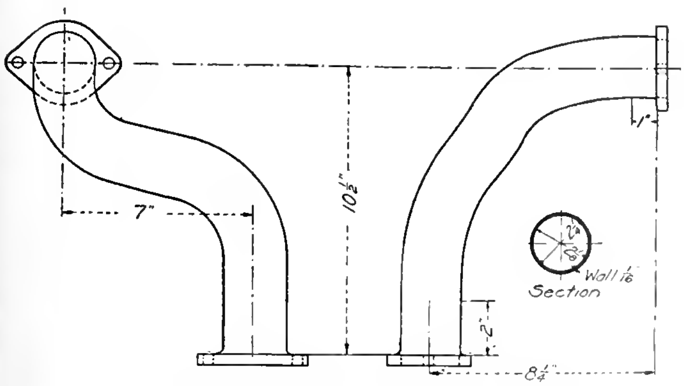

FIG. 6 CROOKED INTAKE PIPE USED FOR TESTS

would be nearly the same in both cases. The planes did not carry full loads such as would be carried, for instance, in bombing expeditions at the front, but the results of the tests were considered to be sufficiently representative to allow computing quite closely the probable flight duration of the Liberty engine in different planes and under various service loads.

Castor oil was used exclusively in one engine and Wolf's Head No. 8 mineral oil in the other. Judging from the condition of the two engines at the end of the runs, castor oil gave slightly better results than the mineral oil, although spark-plug troubles were more frequent in the engine using it.

While both engines unquestionably required overhauling after the 160 hr. of operations in the air, most of the parts were still in fine condition, the crankshaft and connecting-rod bearings being practically the only parts badly worn.

The spark plugs gave the worst trouble, only minor replacements being needed otherwise. It is of interest to note, as regards the condition of the cylinders, that on final inspection after the 160-hr. runs the bores were still in excellent condition and showed a maximum out of round on one engine of but 0.0015 in. and on the other of but 0.002 in. Very little carbon was found on the head.

The general impression is that such troubles as were experienced during these tests were due almost entirely to workmanship,

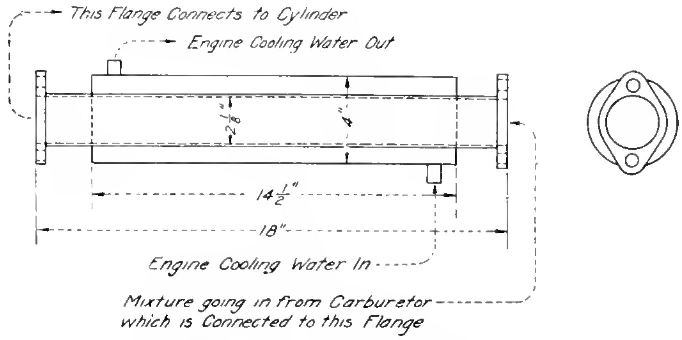

FIG. 7 DIAGRAM OF 18-IN. WATER-JACKETED INTAKE

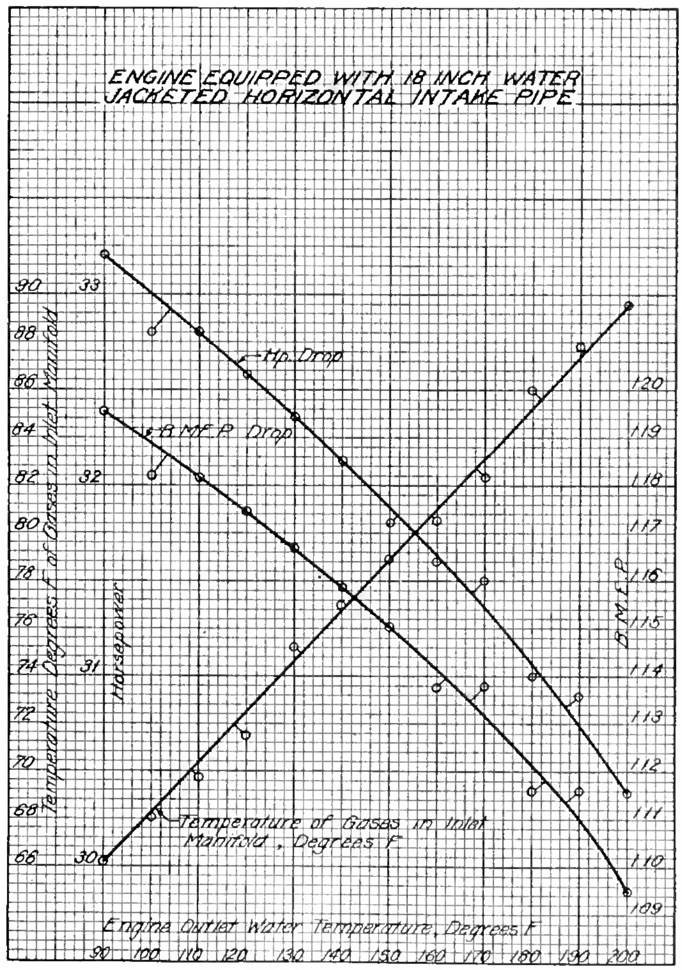

FIG. 8 CURVES SHOWING DROP IN HORSEPOWER WITH INCREASE OF TEMPERATURE OF INTAKE GAS

materials and the personal element that enters into the manufacture and assembly, but not to faults in design.

These tests have brought out conclusively that 125 to 150 hr. is not too much to expect of the Liberty engine without fatigue, which is a very good performance compared with other engines now in operation.

(Concluded on page 295)

BABBITT AND OTHER BEARING METALS

Compositions Recommended by the Committee of the Manufacturers' War Service Association

At the request of the Assistant Chief in Charge of Tin, War Industries Board, the War Service Association of Manufacturers of Solder and Bearing Metals appointed a special committee to study the report of the United States Bureau of Standards to the Conservation Division of the War Industries Board, the suggestions for the conservation of tin which the War Industries Board proposed in a circular letter to users of babbitt and other bearing metals, and other similar documents.

Pending the termination of the researches which are now being undertaken by the Sub-Committee on Bearing Metals of The American Society of Mechanical Engineers, as reported in the January issue of Mechanical Engineering, p. 71, it will be of interest in the meantime to present a brief abstract of the recommendations offered by this special committee of the Association of Manufacturers of Solder and Bearing Metals as a result of their examination of the aforesaid documents and a general survey of the available literature and of the experience of manufacturers and users of bearing metals.

The committee favors the adoption of all the alloys listed by the American Society for Testing Materials in Their Tentative Specifications for White Metal Bearing Alloys, Serial Designation B-23-18-T (See Table 1), subject to the following modifications and additions:

a To increase the allowable maximum for lead in alloys Nos. 1, 2 and 3, providing the Bureau of Standards after complete investigation of the matter of lead content feels that it is safe to do so.

b To increase the arsenic maximum of alloys Nos. 11 and 12 (see Nos. 14 and 15 in Table 2) to 1 per cent.

c Include the following alloys and designate them numerically Nos. 6, 7 and 8 and increase the numerical sequence of alloys Nos. 6 to 12 of the A. S. T. M. accordingly:

	Alloy No. 6	Alloy No. 7	Alloy No. 8
Tin, per cent.	61½	45	30½
Antimony, per cent	10½	7½	8½
Copper, per cent	3	1½	1
Lead, per cent	25	46	60

d Include under the numerical designation Nos. 16 and 17 the lead alloys recommended by the Bureau of Standards in their suggestions for the conservation of tin. (See Table 2.)

Table 1 therefore is modified as represented in Table 2, which shows the composition of the alloys as finally recommended.

The committee believes that the 17 alloys in Table 2 will cover in a very comprehensive manner the number needed to meet every service requirement.

TABLE 1 COMPOSITIONS OF A. S. T. M. TENTATIVE STANDARD ALLOYS

17			98*d*			...

a Maximum. *b* See recommendation (*a*) of committee. *c* Approximate: balance alkali metals. *d* Approximate: balance alkaline earth metals.

With reference to the conservation of tin, the committee proposes the following suggestions:

a For resistance to extreme pressures and impacts, when the design of the bearing is such that a heavy liner is used—Alloy No. 3.

b For supporting smaller loads, or resisting smaller impacts, and when thinner liners are used—Alloy No. 2.

c For the thinnest liners, particularly those attached to bronze or steel backs by the soldering process, and under conditions where the shocks are not so severe as to require the use of harder alloys, either Alloys Nos. 6, 7 or 8, depending on which exhibits the best physical properties (these to be determined by the Bureau of Standards).

d For all classes of service other than *a*, *b*, *c*, *e* or *f*—Alloy No. 10, which is the most satisfactory lead-base babbitt containing tin and antimony.

e For service under low pressures, and without impact, operated at fairly low speeds—Alloy No. 14.

f Alloys Nos. 16 and 17 for the special classes of service for which they may be found suited after sufficient service experience.

Further details are now available regarding the record flight of a U. S. Navy seaplane with 50 passengers at Rockaway on November 27. The machine was an N. C. 1 of the flying boat type, the wings having a span of 126 ft., fitted with three low-compression Liberty engines, each of 385 hp. The normal speed of the machine is 80 miles per hour, but with 50 passengers this was reduced to 72 miles per hour. According to the report of the Aero Club of America, the machine left the water within 1000 ft. at a speed of 45 knots, and rose to a height of 35 ft. It is stated that the machine can climb 2000 ft. in ten minutes.

To overcome a threatened power shortage and to provide power for the rapidly increasing industrial activities in the San Francisco Bay region, the California-Oregon Power Company, the Northern California Power Company, and the Pacific Gas and Electric Company have consolidated, and electric power is now being transmitted continuously over a distance of 300 miles. The surplus power developed in the northern section of the state is thus made available in the industrial district. According to the State Railroad Commission, it is expected the 60,000,000 kw-hr. of energy will be brought to the Bay district annually, with a saving of 20,000 barrels of oil which is now used for the generation of power.

The Loomis Cooling System for Aircraft

A System Embodying a Nose Radiator, an Adjustable Booster and a New Form of Expansion Tank with Positive Ejection

Two features new to airplane cooling systems and which are adaptable to any airplane carrying a water-cooled engine have been developed at McCook Field, Dayton, Ohio, and incorporated in the USD-9A day bombing machine. Particulars of these features, comprising what is known as the Loomis cooling system, appeared in a War Department publication of recent date, which is herewith abstracted by special permission.

THE Loomis cooling system for aircraft was developed at McCook Field, Dayton, Ohio, and first applied to the USD-9A plane. Particulars of this system have been given in a recent issue of the Bulletin[1] of the Experimental Department, Airplane Engineering Division, Bureau of Aircraft Production, War Department, from which the following information has been abstracted by special permission.

The two new features in the Loomis system are an expansion tank that surrounds the core and is an integral part of the nose radiator, thus taking the place of the shell ordinarily used; and an injector in the water connection between the main and booster radiators, which draws water through a nozzle outlet from the bottom of the expansion tank and injects it into the return pipe, thus keeping constant the volume of water in the circulating system.

It is claimed that through these features the loss of water due to steaming or air pockets is minimized and excessive depression in the pump intake is prevented, making possible a much faster water circulation and, therefore, increased cooling efficiency without danger of cavitation in the pump or the drawing in of air around the hose connections on the suction side.

Water from the cylinder jackets enters the upper well of the nose-radiator core in the usual manner, and nearly all of it works down through the core to the bottom of the well, and then through the venturi outlet to the return pipe leading to the booster radiator and the pump. Owing to the action of the venturi, the head of water in the nose-radiator core and the type of pump impeller used, pressure is built up on the intake side of the pump.

A small quantity of water from the upper header of the radiator core normally overflows through holes in the top of the upper well into the expansion tank (Fig. 1) above, and then flows downward in this chamber by gravity. The lowest part of the expansion tank, underneath the lower header of the radiator core, has an outlet nozzle which opens into the throat of, and is concentric with, the venturi outlet from the lower tank. The top of the expansion tank is open to the atmosphere through the vent pipe terminating in the radiator filler neck, so that constant atmospheric pressure is maintained on the water in the expansion chamber, in order that it may be drawn into the return pipe through the action of the venturi at the nozzle.

The auxiliary radiator is located in the water return line between the nose unit and the pump, so that all water from the main radiator passes successively through the venturi and the booster or auxiliary radiator, from top to bottom, before reaching the pump. Fig. 2 shows the connection between the main radiator, injector and booster.

Running entirely around the outside of the nose-radiator core and its upper and lower headers is a separate compartment, $\frac{7}{8}$ in. wide, and of the same depth as the core, which acts as an expansion chamber for the cooling system. The only communications between this tank and the upper well of the radiator core are three $\frac{5}{16}$-in. vent holes. As shown in Fig. 3, the bottom of the well of the core communicates only indirectly with the bottom of the expansion tank through the venturi and nozzle. The injector consists of a $1\frac{1}{16}$-in. diameter venturi outlet from the lower tank or well of the radiator core, with the $\frac{1}{2}$-in. diameter nozzle of the outlet pipe from the bottom of the expansion tank projecting into the throat. The general construction of the outlet is shown in Fig. 3.

Mounted in a vertical rack to the rear of the engine and transversely to the fuselage is the adjustable booster radiator, which is connected in series with the nose unit. The auxiliary radiator may be lowered to project $9\frac{1}{8}$ in. below the bottom cowl of the fuselage, or drawn up into the body until only the edge of the lower tank is exposed.

When the auxiliary unit is lowered to its extreme position, practically its entire surface is exposed to the air stream under the fuselage.

In its upper position this radiator has very little cooling effect, as it is then almost entirely enclosed in the fuselage and only a small amount of air can circulate through it. Most of the air going through the nose radiator is discharged through the louvers in the engine cowls forward of the booster.

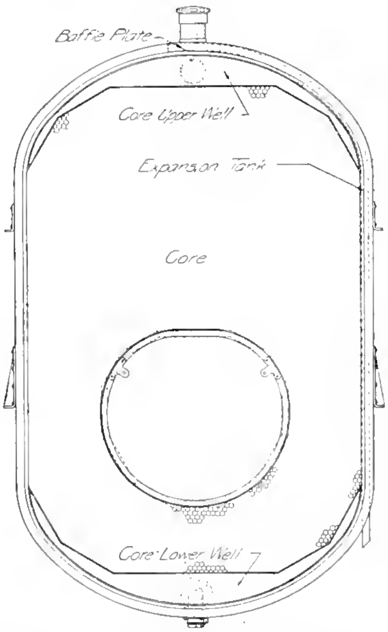

Fig. 1 Diagram Showing the Expansion Tank Around Radiator Core as Used on the USD-9A Plane

The auxiliary cooling unit is raised or lowered by a handwheel on the right side of the pilot's cockpit, which is connected by short lengths of chain and intervening wires with a pinion meshing with a rack attached to the upper part of the auxiliary radiator. The pilot can set the booster unit to project any desired distance below the under side of the fuselage, within the limits provided, in order to obtain the exact amount of cooling capacity needed under different conditions.

While both the nose-radiator shutters and the adjustable-booster unit are provided for the same purpose, that is, to increase or decrease the cooling capacity of the system as a whole, it is the practice to open the shutters first and to lower the auxiliary radiator later, to provide still greater cooling capacity, and vice versa, thereby keeping the parasite resistance down to a minimum.

A series of test flights was made at McCook Field with two DeHaviland-4 planes to determine the relative efficiency of the new cooling system designed for the USD-9A in comparison with other comparable types. Owing to the similarity in size between the DeHaviland-4 and the USD-9A, and to the fact that both planes carry standard Liberty-12 engines, it was considered that the tests would give a good indication of the performance to be expected of the new system in the USD-9A.

The other radiators tested on the same planes for comparison were the Wolverhampton, used in the British DeHaviland-4, and

[1] Bulletin of the Experimental Department, Airplane Engineering Division, U. S. A., McCook Field, Dayton, Ohio, vol. 2, no. 2, November 1918, pp. 61-68. 7 figs.

rated as adequate for a 350-hp. engine, a special American Monogram radiator made by the A-Z Co., and two sample Mayo radiators with ribbon-type cores. These last two were especially designed for the American DeHaviland-4 with Liberty engine. The units tested were near enough alike in general features to offer a fair basis of comparison for the USD-9A system.

By means of preliminary tests a type of pump impeller was selected which was found to be well suited to the new system which produces a certain amount of pressure on the intake side of the pump due to the action of the injector. For use with the Wolverhampton radiator, it was necessary in order to prevent excessive suction to cut down the standard straight-blade impeller with the DeHaviland-4 to 3¼ in. diameter. The regular pump impeller was used without alteration with the other radiators tested. The original report gives the curves of pressure on pump inlet both developed by the straight-bladed pump impeller cut down to 3¼ in. diameter for the English radiator and by the USD-9A radiator with curved-blade impeller used with the Loomis system.

Various precautions described in the original report were taken to insure the correctness and comparability of results obtained with various radiators.

One of the interesting features developed in the tests is that the greatest difference between air temperature and water outlet temperature was found at altitudes between 3000 and 5000 ft., which tends to prove the assertion that a radiator which is adequate up to 3000 ft. under rapid-climb conditions will probably provide sufficient cooling capacity for all purposes.

The following conclusions are made in the report, which also gives the main data secured in tabular form.

Taken on the whole, the USD-9A radiator tests yielded quite good figures for efficiency, which can be depended upon as reliable. The efficiency values obtained in the various trials of this system were:

With no engine top cowl, bottom cowl with extra louvers—91 per cent.

With extra louvers in top and bottom engine cowls, average of two tests—88.8 per cent.

With standard top cowl and no louvers in bottom cowl, average of three tests—87.8 per cent.

These figures indicate that although something is gained by extra louvers in the cowling, still the engine and its front bearer in the USD-9A obstruct the flow of air through the nose radiator to such an extent that the only great gain to be obtained would be by using wide lateral openings in front of these two units to exhaust the air passing through the nose radiator.

Steaming falsifies the apparent efficiency of a radiator, as it reduces the amount of cooling required to be done by the cooling system. A steam calorimeter in the overflow tube would be necessary for accurate corrections.

The only comparisons possible with the other radiators tested must be based on the figures obtained during those trials where no steaming of the other units took place. The comparative results obtained in such tests, with corresponding figures for the USD-9A system, are given in Table 1.

The addition of engine top cowling must produce less effect on the new cooling system than on the other two radiators mentioned in Table 1, for the reason that part of the total cooling surface of the new system, represented by the booster radiator, is independent of all cowling above or below the engine, provided, of course, the lower cowling does not obstruct the auxiliary unit when in its lowest position. The addition of shutters on the nose radiator also produces less effect on the USD-9A cooling system than on the others, and for the same reason.

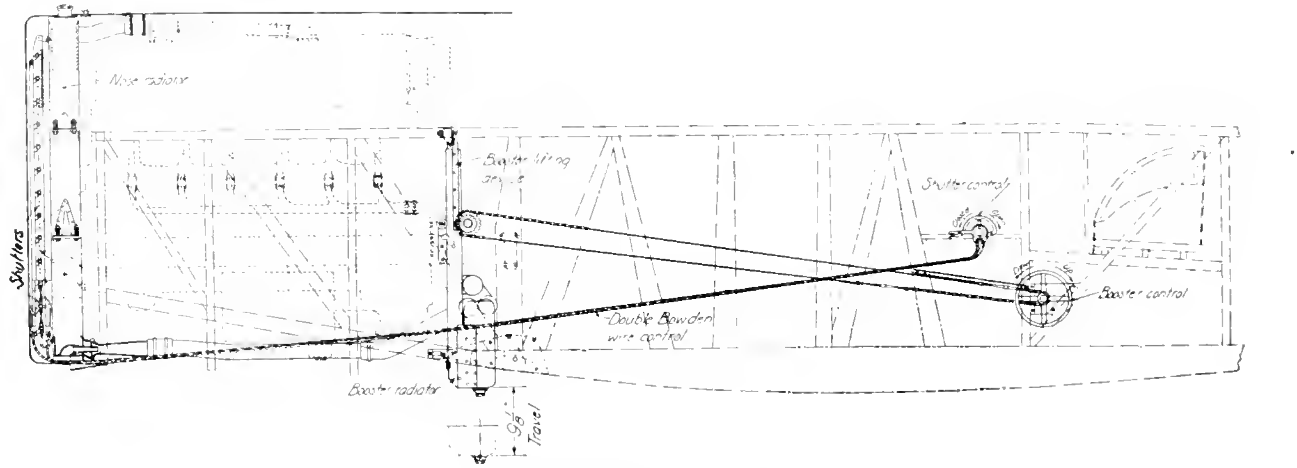

FIG. 2 USD-9A COOLING SYSTEM

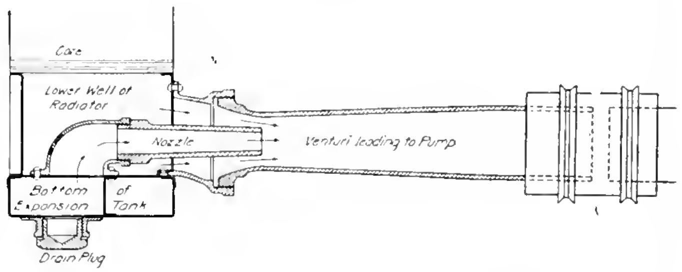

FIG. 3 INJECTOR DEVICE AT BOTTOM OF NOSE RADIATOR

With this radiation system any reasonable increase in cooling capacity can be obtained by adding to the height of the auxiliary radiator. It is quite probable, however, that the present amount of auxiliary radiation is sufficient in view of the fact that very little steaming was encountered even under the severe conditions of the tests. Under ordinary conditions the high-compression Liberty engine is not intended to be run at full throttle near the ground, as was done in these tests.

TABLE 1 COMPARATIVE EFFICIENCY OF RADIATORS

Radiator	Efficiency, per cent	Cooling surface, sq. ft.	Weight full, lb.
Monogram	76 75	202	176 5
Wolverhampton	82 5	246	142
USD-9A	91	219	204 5

The United States Navy Department has successfully carried out the experiment of launching an airplane from a dirigible balloon. The airplane was attached by a 100-ft. cable to the dirigible; both rose to about 3,000 ft. and then the airplane was released; after diving about 1,000 ft. it obtained sufficient speed to continue its usual flight.

STRESSES IN WIRE ROPE

Development of a New Formula for the Determination of Bending Stresses

By SHORTRIDGE HARDESTY,[1] KANSAS CITY, MO.

At the December 1918 Annual Meeting of the Society a valuable paper on the Determination of Stresses in Wire Rope as Applied to Modern Engineering Problems was presented by James F. Howe, Wire Rope Engineer of the American Steel and Wire Company, Worcester, Mass. This paper has drawn out the accompanying contribution by Mr. Hardesty. A very full review of Mr. Howe's paper was given in The Journal for December 1918, p. 1016.

THE writer has been deeply interested for some time in the subject of wire-rope stresses, upon which Mr. Howe has written, and submits the following notes on a few points to which he has given considerable study.

Mr. Howe brings out the point that while the modulus of elasticity in tension of the material in the wires is 27,500,000, the corresponding value for an entire rope of standard 6 x 19 construction is about 12,000,000; or, in other words, that the rope stretches about 2.3 times as much as would one made of straight wires. Different investigators in the past have found values of this function ranging from 12,000,000 to 17,000,000. For any given rope its value depends somewhat upon the age and condition of the rope. For a new, well-lubricated rope, 12,000,000 is correct; while in an older rope, in which the hemp center has been compressed and has become hardened, a larger value will be found. If, however, the rope is subjected to bending over small sheaves, the hemp center will be continually worked and stretched, and the rise in the value of the modulus of elasticity will be much smaller.

It is not difficult to explain why the rope stretches more than would a bundle of straight wires. A 6 x 19 rope is composed essentially of 114 spiral springs. Under tension these springs stretch out, the diameters of the helices reducing slightly. This stretching-out action does not occur freely, as the tightly twisted wires and strands interfere with each other. In a new, well-lubricated rope, the helical strands can pinch down considerably on the elastic core, the amount of stretching out is large, and the modulus is small; while after the core compresses and becomes hardened, the strands cannot pinch down so much, the amount of stretching out reduces, and the modulus becomes greater.

Mr. Howe discusses the question of the stiffness of an ordinary wire rope as compared with that of a rope composed of straight wires, calling attention to the fact that the ordinary rope is much more flexible. He concludes that, on account of the lower modulus of elasticity in tension of the ordinary rope, the bending stresses produced in the individual wires are correspondingly smaller than those in the straight wires, and thus accounts for the greater flexibility. From this reasoning we would expect the ratio of the stiffnesses of the two ropes to be 2.3 to 1. Actually, however, this ratio is much larger than 2.3 to 1. The writer suggests the following explanation of the greater flexibility of the ordinary rope:

If a rope composed of straight wires, having the same number and arrangement of wires and strands as the standard 6 x 19 rope, be bent around a sheave, certain wires will lie on the outside of the curve throughout, and must evidently elongate and be subjected to tensile stresses in addition to bending stresses, while other wires will lie on the inside of the curve throughout, and will receive compressive stresses as well as bending stresses. On account of the axial stresses being thus produced in the wires, the stiffness of the rope will be much greater than that of the 114 wires themselves—about 200 times as great if all of the stretching or shortening of the wires has to occur in the bent portion of the rope, and probably 50 to 100 times as great if the stretching or shortening of the wires can extend out into the straight portions of the rope, as will usually be the case.

Consider now a piece of ordinary 6 x 19 wire rope, say 1 in. in diameter. The strand which lies at the top of the rope at one point is at the bottom about 3 in. away; and the wire lying at the top of a strand at one point is at the bottom about $1\frac{1}{4}$ in. away. If such a rope, well lubricated, be bent around a sheave, evidently it is unnecessary that any large axial stresses be set up in the wires. Instead, the strands will slip along the core and the wires will slip along each other in the strands. Evidently, then, the wires will be subjected to bending stresses, and in addition only to sufficient axial stresses to make the strands slip along the core, and the wires along each other. These axial stresses will be negligible in a well-lubricated rope.

From the foregoing it is clear that the ordinary rope is much more flexible than the rope composed of straight wires, for the reason that in bending the latter there are set up large axial stresses, as well as bending stresses, in the individual wires, while in bending the former there are set up bending stresses only in the wires. Evidently, therefore, we cannot argue from the greater flexibility of the ordinary rope that the bending stresses in the wires are smaller than those in the rope composed of straight wires.

Mr. Howe, having deduced 12,000,000 as the value of the modulus of elasticity in tension for the entire rope, then assumes that this value can be used in computing the bending stresses in the separate wires, and thus obtains values about half those which have generally been accepted. The writer can see no direct reason why the modulus of elasticity in tension should necessarily apply to the calculation of bending stresses in the separate wires, and feels that the author should give his reasons for making this assumption. The point certainly requires explanation.

The writer has put considerable study on the question of bending stresses in wire ropes, and offers the following formula. It is simple and logical in derivation, so far as he can see, and it agrees with the only tests bearing directly on the question of which he has any knowledge.

Suppose a straight wire of diameter d to be bent 180 deg. around a sheave of diameter D. The length of the bent portion of the wire is $\pi D/2$ and the total angle through which it is bent is π, so that the angle of bending per unit length is $\pi/(\pi D/2)$ or $2/D$. Letting f be the extreme fiber stress in the wire and E the modulus of elasticity of the material, the angle of bending per unit length is also $(f/E)/(d/2)$, or $2f/Ed$. We then have

$$\frac{2f}{Ed} = \frac{2}{D}$$

whence

$$f = E\,\frac{d}{D}$$

This latter expression is the formula given by Reuleaux, Rankine, Unwin, and other writers, and is evidently applicable to straight wires only.

Now consider a helical wire, such as the center wire of one of the strands of a wire rope. Let the angle between the wire and the axis of the helix be a, and other notation as before. Now suppose the helical wire bent 180 deg. around the sheave. The total angle through which the wire is bent is evidently π, as before, and the length of the bent portion is $(\pi D/2)\sec a$; so that the average angle of bending per unit length is evidently $\pi/(\pi D/2)\sec a$, or $(2/D)\cos a$. We then have

$$\frac{2f}{Ed} = \frac{2}{D}\cos a, \text{ whence} \qquad f = E\,\frac{d}{D}\cos a$$

Next consider a compound helical wire, such as one of the outer wires in a strand of a rope. Let the angle of lay of the strand be a, and the angle of lay of the wire in the strand be b. As before, suppose the wire bent 180 deg. around the sheave. The length of the bent portion of the wire is $(\pi D/2)\cos a\cos b$, whence we find

$$f = E\,\frac{d}{D}\cos a\cos b$$

[1] Of the firm of Waddell & Son, Inc., Consulting Engineers.

It appears difficult to the writer to consider the bending stresses to be any smaller than those given by the foregoing formulæ. The total length of the wire and the total angle through which it is bent are known, definite quantities in each case, from which we can deduce directly the average angle of bending per unit length; and from this latter quantity the extreme fiber stress in the wire can be computed directly and without any doubt whatsoever.

While the last-mentioned formula thus appears to be correct, it is, of course, very desirable to check it experimentally. The results of some experiments given in a paper by Mr. R. W. Chapman in the *Engineering Review* of October 1908, entitled The Stress in Wire Ropes Due to Bending, offer an opportunity

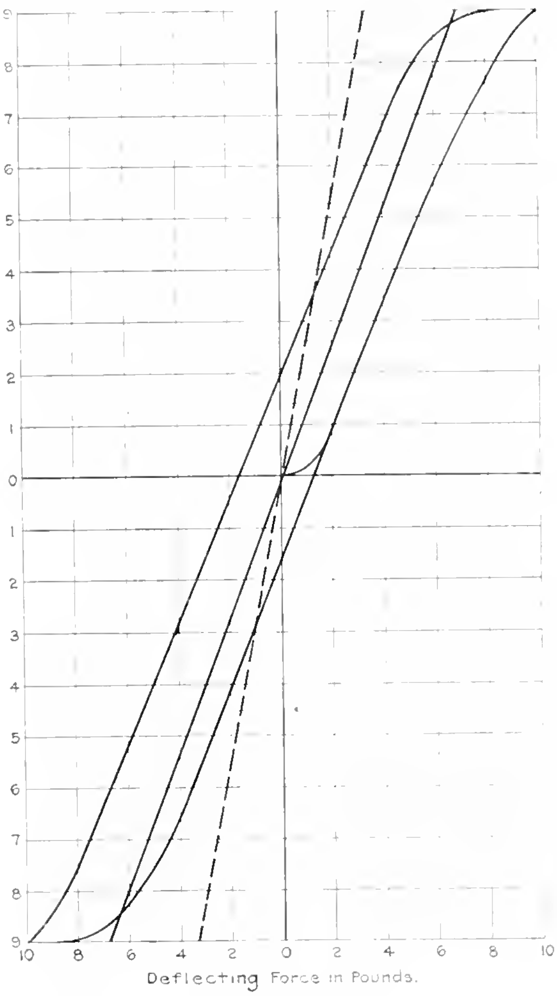

FIG. 1 DEFLECTION OF 6 x 12 WIRE ROPE WITH LOAD 24 IN. FROM SUPPORT

for such a check. Mr. Chapman took a short length of wire rope, clamped one end securely, applied transverse forces to the other end, and then measured the resulting deflections. Figs. 1 to 4 record graphically the results of four of his experiments.

In making such an experiment, evidently we must allow for the effect of the internal frictional forces between the various strands and wires. Mr. Chapman eliminated the effect of these forces in the following manner: He first applied a gradually increasing force in one direction, then reduced it gradually to zero, then applied a gradually increasing force in the other direction, and then gradually reduced it to zero. When the first small forces were applied the deflections were very small, as the wires and strands had not yet begun to slip on each other, and the rope had nearly the stiffness of a solid bar. The flat portion of the deflection curve just to the right of the origin in each figure corresponds to this stage. As the forces were increased the internal friction was overcome, the wires and strands began to slip freely on each other, and the deflection curve turned up sharply and continued practically a straight line as long as the forces were increased. The reduction of the forces then began. The resulting deflection curve was at first very flat, the rope acting as a solid bar while the direction of the internal frictional forces was reversing; then the curve turned down sharply as slippage in the opposite direction began. The forces were then gradually reduced to zero and then applied in the opposite direction, the deflection curve continuing downward as a straight line meanwhile. The forces were then reduced gradually to zero, the deflection curve being at first very flat, then turning up sharply and continuing as practically a straight line. The forces were again reversed in direction, the curve continuing upward and joining the curve first drawn, thus forming a complete loop.

In the loop just described the nearly horizontal portions at the top and bottom, as stated before, represent the deflection curve when no slippage of wires and strands occurs; while the long, steeply inclined sides represent the curve when the wires and strands are slipping freely, with the effect of internal friction eliminated.

Our next step is to compute the theoretic deflection curves for each of the four examples in accordance with the formulæ for bending stresses deduced by Mr. Howe and the writer, and to plot them on the four figures.

The rope used in the tests plotted in Figs. 1 and 2 consisted of 6 strands of 12 wires each, with a hemp core for the rope and hemp cores for the strands. The rope was of ordinary lay, the angle of lay being $18\frac{1}{2}$ deg., and the diameter of the wires 0.082 in. The moment of the inertia of the 72 wires is $72 \times 0.082^4 \times 0.0491 = 0.000159$. The value of EI, according to Mr. Howe's formula, is $12{,}000{,}000 \times 0.000159 = 1910$; while according to the writer's formula, since $\cos 18\frac{1}{2}$ deg. $= 0.95$, it is $27{,}500{,}000 \times 0.000159 \times 0.95 \times 0.95 = 3950$.

For Fig. 1, the distance from the support to the end of the rope was 26 in., and the distance from the support to the load was 24 in. The deflection y of the end for a load P is therefore

$$y = \frac{24P \times 12 \times 18}{EI} = \frac{5180P}{EI}$$

For Mr. Howe's formula, $y = 5180P/1910 = 2.71P$, and for the writer's formula, $y = 5180P/3950 = 1.31P$.

For Fig. 2, the distances from the support to the end of the

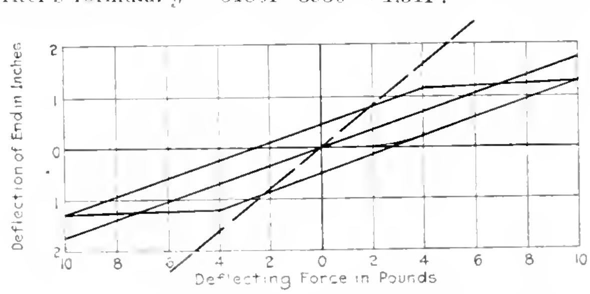

FIG. 2 DEFLECTION OF 6 x 12 WIRE ROPE WITH LOAD 12 IN. FROM SUPPORT

rope and to the load point are 14 in. and 12 in., respectively, so that the deflection of the end is

$$y = \frac{12P \times 6 \times 10}{EI} = \frac{720P}{EI}$$

For Mr. Howe's formula, $y = 720P/1910 = 0.376P$, and for the writer's formula, $y = 720P/3950 = 0.182P$.

The rope used in the tests recorded in Figs. 3 and 4 was a Lang lay rope consisting of 6 strands of 7 wires each, the diameter of the wires being 0.111 in. The lay was not stated, but may be assumed as $18\frac{1}{2}$ deg. The moment of inertia of the 42 wires is $42 \times 0.111^4 \times 0.0491 = 0.000313$. The value of EI, according to Mr. Howe's formula, is $12{,}000{,}000 \times 0.000313 = 3760$; and according to the writer's formula it is $27{,}500{,}000 \times 0.000313 \times 0.95 \times 0.95 = 7780$.

For Fig. 3, the distances from the support and the load point are 23 in. and 21 in., respectively, so that the deflection of the end is

$$y = \frac{21P \times 10.5 \times 16}{EI} = \frac{3530P}{EI}$$

For Mr. Howe's formula, $y = 3530P/3760 = 0.94P$; and for the writer's formula, $y = 3530P/7780 = 0.455P$.

For Fig. 4, the distances from the support and load point are 16 in. and 14 in., respectively, so that the deflection ot the end is

$$y = \frac{14P \times 7 \times 11.33}{EI} = \frac{1110P}{EI}$$

For Mr. Howe's formula, $y = 1110P/3760 = 0.295P$; and for the writer's formula, $y = 1110P/7780 = 0.143P$.

The deflection curves computed by the writer's formula have been plotted on each of the four figures as straight full lines, and those figured by Mr. Howe's formula as straight dotted lines. It will be noted that in each figure the full line is approximately parallel to the deflection curve when the wires and strands are slipping freely, with the effect of internal friction eliminated; while the dotted line does not agree at all with these deflection curves. These tests therefore indicate the substantial correctness of the formula proposed by the writer and the incorrectness of the one proposed by Mr. Howe.

The foregoing experimental data, while meager, are all that the writer has been able to find bearing on this subject. It is to be hoped that it can be supplemented in the near future by an extensive series of tests. Mr. Howe, as an engineer of a wire-rope company, may be in a position to carry out such experiments. The question of bending stresses in wire ropes has long been discussed from the theoretic standpoint, and also in its purely practical features; and it seems high time that the two aspects be combined in a scientifically conducted series of tests.

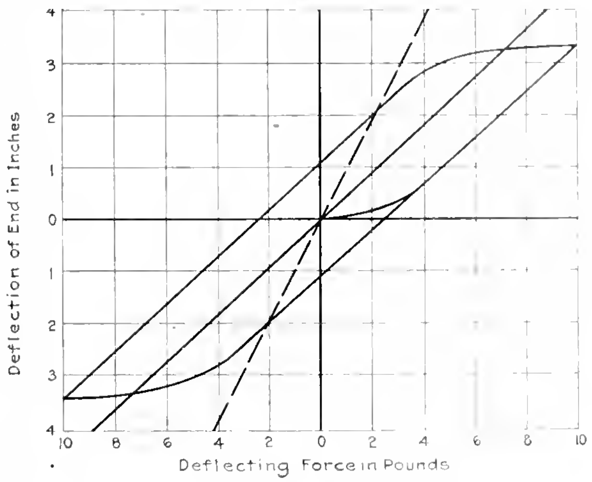

FIG. 3 DEFLECTION OF 6 x 7 WIRE ROPE WITH LOAD 21 IN. FROM SUPPORT

Practical working rules for design can be easily developed from the formula deduced by the writer, namely,

$$f = E\frac{d}{D}\cos a \cos b$$

E can be taken as 27,500,000. For a 6 x 19 rope d equals about $c/15$, where c is the diameter of the rope. Cos a can be taken as 0.95; cos b is 1.00 for the center wire of each strand, 0.97 for the second row of wires in each strand, and 0.95 for the outer row. We then have the following expressions:

Center wire of strand:

$$f = 27{,}500{,}000 \times \frac{c}{15D} \times 0.95 = 1{,}740{,}000\frac{c}{D}$$

Second row of wires:

$$f = 1{,}740{,}000\frac{c}{D} \times 0.97 = 1{,}690{,}000\frac{c}{D}$$

Outer row of wires:

$$f = 1{,}740{,}000\frac{c}{D} \times 0.95 = 1{,}650{,}000\frac{c}{D}$$

As an average value, we can use

$$f = 1{,}700{,}000\frac{c}{D}$$

Since the area of the rope is approximately $0.4c^2$, the product of the unit bending stress by the area is

$$680{,}000\frac{c^3}{D}$$

It has been mentioned that when a rope is bent around a sheave, axial stresses are produced only great enough to make the strands and wires slip, and that for a well-lubricated rope they will be negligible. This is borne out by Mr. Chapman's tests, the widths of the loops being small. If the lubrication be poor, the axial stresses will be larger; and if the rope be rusted so that slippage cannot take place, the axial stresses will be dangerously high. These facts point to the imperative need for thorough lubrication

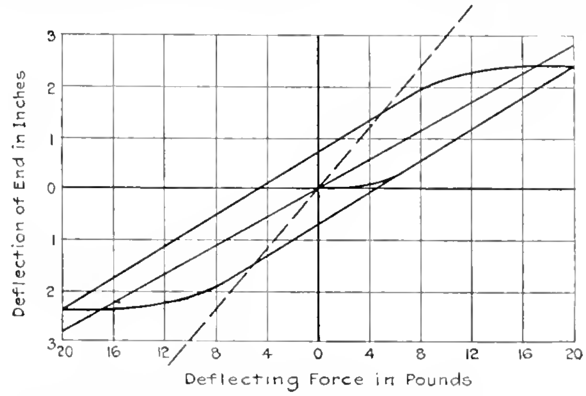

FIG. 4 DEFLECTION OF 6 x 7 WIRE ROPE WITH LOAD 14 IN. FROM SUPPORT

and protection of wire ropes. The lubricant chosen must be one which will penetrate to the inside of the rope and thoroughly saturate the hemp core. A heavy dressing which merely forms a coating on the outside of the rope may be worse than useless, for it may give a false sense of security, while the inside of the rope is devoid of lubricant and possibly even rusting. If an extensive series of bending tests is made, an attempt should be made to secure quantitative values of the stresses in poorly lubricated ropes.

Mr. Howe mentions the destructive effect of reversed bending in ropes. This point cannot be too strongly emphasized. The writer is inclined to believe that reversed bending over sheaves of diameter 60 times that of the rope is nearly as bad as bending in one direction over a sheave of diameter 30 times that of rope.

Mr. Howe also mentions the possibility of using 6 x 37 and 6 x 61 constructions for large ropes. He suggests 6 x 37 ropes for 1½-in. to 2-in. diameters, and 6 x 61 ropes for diameters over 2 in. The writer would hardly agree with these limits for lift-bridge work, as a great deal of trouble is experienced in keeping the ropes properly lubricated, and this fact would discourage the use of smaller wires than is necessary. He would suggest, for this service, that 6 x 19 ropes be used up to 2¼ in. diameter, and 6 x 37 ropes for larger diameters.

MR. HOWE'S COMMENT ON THE PROPOSED FORMULA

The foregoing discussion of his paper was submitted to Mr. Howe, who comments thereon as follows:

The formula as proposed by Mr. Hardesty, namely,

$$f = E\frac{d}{D}\cos a \cos b$$

will give as applied to ordinary 6 x 19 wire rope, assuming that $\cos a = 0.95$ and $\cos b = 0.95$, a value for $\cos a \cos b$ of 0.9025. If this is multiplied by E, it will mean, assuming E to be 27,500,000 as proposed by the writer in his paper, that the modulus of elasticity of the entire rope would be equal to the product of 0.9025 and 27,500,000 or 24,818,750 lb.: or in other words, the modulus of elasticity of the wire rope would be only about 10 per cent less than the modulus of the straight wires. Experimental proof has shown that the modulus is much less than this, as will be noted by reference to curves shown in Figs. 6 and 7 of the paper, the latter of which appeared as Fig. 4 on p. 1018 of THE JOURNAL, December 1918.

Reference has been made by Mr. Hardesty to the paper delivered by W. R. Chapman, published in the *Engineering Record* in 1908, in which Mr. Chapman gave particulars of experiments made to show the value of the bending stress in wire ropes. In that paper Mr. Chapman gives for a 3¼-in.-circumference rope (1.034 in. diameter) a bending stress of 18,945 lb. over a 3-ft. sheave. This corresponds to a modulus of elasticity of approximately 24,300,000 lb., which agrees with Mr. Hardesty's formula. However, Mr. Hardesty is basing his conclusions entirely upon the Chapman experiments, so that the agreement of his formula with the Chapman experiments is by no means conclusive evidence of the correctness of the assumptions which have been made.

The entire experimental proof of Mr. Chapman rests upon a series of experiments made by clamping a piece of wire rope in a solid jaw, suspending this rope vertically and then applying various loads at the end of this rope and recording the deflections. For ordinary testing where the material being tested is a solid, this method would probably give fairly correct results; but in testing wire rope in this manner, very serious complication has been allowed to creep in which completely nullifies the results obtained. This will be readily understood when the structure of wire rope is examined. When the clamp is placed upon the wire rope, it is bound solid and no action can take place. Furthermore, the lower end of the wire rope must be held solid in a seizing of wire. This prevents any play of the strands either at the end of the rope or at the point where they are clamped. The distance in between is so short that it seriously affects the results obtained, because it gives a much greater stiffness to the rope than is possessed by the rope under actual working conditions. Any person who has handled wire rope knows that the effect of binding both ends of a short piece of rope is to render it very stiff. If the piece of rope is lengthened, this stiffness is overcome. However, experiments of this kind, while they are interesting, do not give true results as to the working of a full-length specimen of rope, and this is what the engineer wants to know. Behavior of a short specimen under bending does not concern him. It is what the specimen will do when it is put to work in commercial lengths on a large outfit.

Taking the case already cited, namely, the 1.03-in.-diameter rope working over a 3-ft. sheave, the bending stress on a sheave 1 ft. 6 in. in diameter would be, according to Mr. Chapman, 18.94 tons. A rope of this diameter would have an ultimate strength of 30 tons for crucible steel, or 38 tons for plow steel. It is not an unusual case for a derrick to be equipped with rope working under these conditions, carrying a load of 6 to 7 tons. Were the bending stresses as high as these Chapman experiments would indicate, the life of the rope would be exceedingly short, because the material would be worked at or near the elastic limit at all times, even without any additional load. Other similar cases might be cited wherein these conditions are duplicated. This of itself is conclusive proof that the bending stress cannot be as great as would be computed either by the Chapman formula or by Mr. Hardesty's formula as he proposes it.

Were the stress as high as calculated by Messrs. Chapman and Hardesty, wire rope would give practically no service at all under the conditions noted, whereas we know of numerous cases where ropes have lasted from six to eighteen months under conditions similar to those just noted. The practical results of rope operation offer added proof, therefore, that the bending stress is a much smaller factor than indicated by Mr. Hardesty's calculations.

In a note dealing with the possibilities of the commercial airships, issued recently by the British Air Ministry, it is predicted that future airships will have a capacity of 10,000,000 cu. ft., a propelling apparatus of 6000 hp., and a maximum speed of 85 miles per hour. These ships would be 1000 ft. in length, 150 ft. in overall height, possess a range of 20,000 miles, and could stay aloft for three weeks without requiring refilling. The crew would consist of three officers and 26 men, and the freight capacity would be 200 tons. The cost of a 10,000,000-cu. ft. airship is estimated at between $1,000,000 and $1,500,000. From *Aviation*, February 1, 1919.

RECOLLECTIONS OF ERICSSON

As the ninth of this month marks the thirtieth anniversary of the death of the noted engineer, Captain John Ericsson, it has been thought fitting to recall his many and great achievements, as recounted by his friend, George H. Robinson, in Recollections of Ericsson, a published address which was delivered before the Commercial Club at Providence, R. I., on March 24, 1894. This little book has recently been donated by George L. Shepley to the Society to be placed in the Library, and the following paragraphs are reprinted as showing the variety and scope of Captain Ericsson's work.

In John's earliest boyhood his delight was to be in the mines studying the machinery and making drawings. At the age of nine he constructed a sawmill, using a watch spring for a saw, transformed by the aid of a file borrowed from a neighboring blacksmith, and

John Ericsson, the Thirtieth Anniversary of Whose Death Occurs on March 9

From a Painting Presented to the Society by the Late Prof. F. R. Hutton

from a broken tin spoon he cast his crank. He built a water wheel and attached his sawmill to it, and had the delight of seeing the machinery in actual operation sawing sticks. The next summer he designed a pump for drawing water from the mines. The motive power was derived from a windmill. He had never seen a windmill, but he built it from descriptions given by his father. It failed to work because it had not been adjusted to the changes of the wind. His father, describing a visit to a neighboring mine, spoke of a ball and socket joint. The idea was seized at once by John, and he joined the connecting rod for his crank to the pump lever with a ball and socket joint. From early infancy John Ericsson was connected with great engineering works, the Göta Canal being a marvel of canal building even for the present day.

At seventeen the military spirit took possession of him, and after much opposition from his engineering advisors he was assigned to the 23d Regiment Rifle Corps, with the rank of ensign. Soon after he joined the service orders were given to survey the District of Jemtland, where he was stationed. The work was secured by competition, and Ericsson easily won a prize. Ericsson was so rapid of execution that he performed more than double duty, and he was carried on the payrolls as two persons in order to avoid criticism and charges of favoritism. At the age of twenty-two he constructed the flame engine.

Showing the drawings of his flame engine to King Charles, he was advised to go to England, where he could find a more fitting field for his ambition.

Now followed invention after invention in rapid succession. An engine using steam combined with the gases arising from the combustion of coal; next a start toward his future caloric engine—an engine with two cylinders; in one of these was a loosely fitting piston, and directly under this he placed his fire, the loosely fitting piston actuating his working cylinders. Then he constructed a pumping engine, consisting of a series of cisterns rising one above the other; by ex-

hausting the air from these cisterns in succession the water was raised to the desired height.

In 1828 he constructed an air compressor, which was placed in successful operation in the mines near Truro, in Cornwall. It had an air cylinder of twenty inches diameter and five feet stroke.

In 1828 he patented artificial draught, a year before Stephenson made his reputation by the application of the same principle to his locomotive "Rocket." The year 1828 was marked by another revolutionary invention by Ericsson, the steam fire engine. He built several, but a generation passed before his invention was used, and then his fire engine came into service almost without change.

Now comes the era of locomotive building. The officials of the Liverpool & Manchester Road published an advertisement offering a prize of £500 for the best locomotive conforming to certain stipulations. Five months were allowed for completing the engine. Of the twenty-two weeks, fifteen had passed before Captain Ericsson learned of the competition. He had seven weeks only to make his plans and build his machinery. He had never built a locomotive. John Stephenson was engineer of the Liverpool & Manchester Road, and had been five years at the head of an establishment manufacturing such locomotives as were in use in the colleries; and he had the further advantage of controlling the road that ordered the trials, and the sympathy and support of its officials. His locomotive "Rocket" was virtually completed before Ericsson's "Novelty" was begun. Stephenson tested the "Rocket" in actual practice and remedied its defects, that would have been fatal if left to the day of trial. Ericsson could make no test before trial, and on that day he had to adjust the wheels of the "Novelty" to fit the track. Stephenson had been obliged to conceal the speed he hoped to attain, and ten miles had been spoken of as the limit of possible speed.

For the trials five engines entered; three were of little moment. The contest was between the "Rocket" and the "Novelty." Stephenson depended on chimney draught. Ericsson provided his engine with artificial means for supporting the combustion in the boiler furnace. A blowing machine was applied, moved directly by the engine so that the supply of air was greatest when the engine worked at maximum speed. The result was the "Novelty" shot by the "Rocket" like a projectile. The "Novelty" did a mile in fifty-six seconds. The second day the "Novelty" blew out several tubes and Ericsson withdrew her from the contest. The following year Ericsson built two locomotives—the "King William" and the "Queen Adelaide." To these was applied for the first time the link motion for reversing steam engines.

In 1830 he patented an apparatus for making salt from brine. In 1831 a rotary engine; two were built on a large scale, one being placed in a steamship. The next year he applied a centrifugal fan blower, driven by a separate small engine, to the steamer "Corsair." The independent blower system is now universally adopted, but not one in ten thousand who uses it knows to whom he is indebted.

In 1833 he took out his first patent for caloric engines. The use of high temperature in the air engine suggested another step with steam. He followed with his "Superheating Condenser Steam Engine." The deep-sea sounding machine, known as Ericsson's Sea Lead, was his next important invention.

In 1836 he patented an automatic file-cutting machine. The next greatest gift to this century—the invention that revolutionized commerce, that made possible the utilization of that other great invention, the cable—was the screw propeller. This was the first direct-acting screw-propeller engine ever built.

In 1854 Ericsson sent to Napoleon III a plan of a monitor, differing only from what is known as the original "Monitor," in that the turret was a rounded dome. These plans were not adopted, but the Emperor was greatly interested, acknowledging them personally and sending Ericsson a gold medal testifying his appreciation.

In 1862, when the days of our Civil War were darkest, the Southern Confederacy was fitting out the "Merrimac"; with her they hoped to capture every port on the seaboard, destroy our commerce and compel the surrender of Washington. Ericsson, the best-equipped American of the day, was entirely ignored. He had become a citizen in 1848. His friend, DeLamater, was familiar with the plans sent to Napoleon. These plans had been the result of thirty years' study, and were conceived in his boyhood. "You assume correctly," he wrote to his friend Fox, in 1875, "that the plan of the 'Monitor' was based on the observations of the behavior of timber in our great Swedish lakes. I found that while the raftsman in his elevated cabin experienced very little motion, the seas making over his nearly submerged craft, those seas at the same time worked the sailing vessels on their beam ends." He saw then the impregnable warship and only waited the call.

On August 3, President Lincoln approved an act appointing a board to determine upon building ironclad steam vessels. An advertisement inviting proposals was published. One of the first sets of plans recommended for adoption by the Committee was presented by C. S. Bushnell, and he was awarded a contract to build the vessel known as the "Galena." He consulted Mr. DeLamater, many of the naval men having doubted her ability to carry the stipulated amount of iron. Mr. DeLamater advised him to go to Captain Ericsson, whose opinion would settle the matter definitely and with accuracy. He called on Ericsson, laid the matter before him and was requested to call the next day for his verdict. It was entirely favorable. Captain Ericsson then produced his model and plan of a monitor sent to Napoleon. He found a most willing champion in Bushnell, and gave him both plan and model to present at Washington.

The next day the board condemned the plan. Bushnell labored with them and won over Admirals Smith and Paulding, who promised to report favorably if Captain Davis would join them. Captain Davis told Bushnell "to take the little thing home and worship it, as it would not be idolatry, because it was in the image of nothing in the heaven above or on the earth beneath, or in the waters under the earth."

Bushnell felt that the only way to succeed was to have Captain Ericsson present in Washington. He came to New York, saw Mr. DeLamater, and together they went to Beach Street. The exact facts were not given to Captain Ericsson, but he was told that some explanations were needed that he alone could make. He went to Washington that night. He was told as soon as he appeared before the board that his plans had been rejected. His indignation impelled him to withdraw at once, but he wisely asked why the plan was rejected. He was told the vessel lacked stability. He explained with elaborate demonstration and so convincingly that Commodore Paulding said frankly and generously: "Sir, I have learned more about the stability of a vessel from what you have said than I ever knew before." He was told the next day by Secretary Welles that a contract would be awarded, and asked to proceed at once with the work. The contract was signed October 25, 1861. The keel of the "Monitor" was laid on the same day. Steam was applied to the engines at DeLamater Iron Works December 30th. She was launched January 30th, and practically completed February 15, 1862. She made her first trial trip February 19th. Ericsson's work during that three months was herculean. Not only the necessary labors, but the worries from continued doubts sent from Washington required almost superhuman power.

The "Monitor" left New York harbor March 6, 1862, commanded by Commodore Worden. She arrived at Hampton Roads on the morning of the 9th, and before the sun set that day the famous battle of the "Monitor" and the "Merrimac" was done. What was due to the man whose brain had conceived and whose will had directed this mighty work that had delivered a nation? The "Monitor" conquered the "Merrimac" before payment had been made, before she had been accepted by the Government.

The war vessel was changed in one day. The monitor type became the war vessel of the world.

Ten years later we had the "Cuban scare," and the "Dictator" was hurried into active service. She left for the rendezvous in charge of her consort, who lost her off Savannah during a bad storm. The consort put into that port, and it was telegraphed from there that the "Dictator" was lost and all on board. Captain Ericsson was overwhelmed at the news, but, seeking a cause, he finally concluded that her steering gear had become disarranged. The next morning Captain Ericsson sent word: "He had been thinking all night, and had concluded that her steering gear could not get disarranged. The "Dictator" would report at Key West within twenty-four hours." She arrived at Key West a few hours later.

In 1869 the Spanish government wished to protect Cuba from filibusters and insurgents. Captain Raphael de Aragon came to Messrs. DeLamater & Co. commissioned to spend a considerable sum, but without any plan. Naturally, Ericsson was consulted. He had just been studying the defense of Sweden and suggested a scheme at once; to build thirty gunboats, each armed with a 100-pound gun mounted on her bow. He named two conditions only—to make his plans without submitting, and that DeLamater should execute the contract. These thirty boats were completed in thirty weeks, and some years later the designer and builder each received from the Spanish government the Commander's Cross of the Order of Isabel la Catolica, in recognition of their services.

Ericsson now was at work on harbor defense, and developed, after years of trials, the "Destroyer," which carried a submarine gun and discharged a projectile thirty feet long, loaded with three hundred and fifty pounds of explosive. For General Grant a test was made, and she performed what her designer claimed for her. She hit a target ten feet square, ten feet below the surface of the water, and traversed the distance—300 feet—in less than three seconds' time.

I am aware of what injustice I am doing Captain Ericsson's work; I cannot even speak of his conclusive researches regarding solar heat, of the solar engine he built and ran in Beach Street, developing ten horsepower from the direct rays of the sun; of the caloric ship "Ericsson," of his numberless achievements. The history of his honors and decorations almost universally conferred would alone considered make an interesting talk. He was recognized by every Government in Europe and by most of the leading societies in the world. He received in 1862 for his "Caloric Engine of 1858" the gold and silver Rumford medals. The prize was founded in 1796 by Count Rumford, a native of Concord, N. H., and was in the gift of the American Academy of Arts and Sciences. They awarded it in 1839 to Robert Hare 43 years after its foundation, but 23 more passed before another was found worthy of the award.

On March 9, 1889, on the anniversary of the battle of the "Monitor" and the "Merrimac," came to this man rest.

On August 23, 1890, the remains of Captain Ericsson were placed on board the "Baltimore" and sent to Sweden. His native government asked it. His adopted government granted it with every honor possible, sending him home on her finest warship.

ENGINEERING CONDITIONS IN FRANCE

Return of American Engineer-Delegates Who Have Been Conferring with French Engineers on Reconstruction Problems. Meetings Held in Boston and New York

As announced in The Journal for December 1918, an invitation was extended to the American Society of Civil Engineers by the Société des Ingénieurs Civils and the Committee of the French Engineers' Congress, for a delegation of American engineers to go abroad to discuss some of the problems involved in the rehabilitation of France. The delegation was organized by the Civil Engineers with the coöperation of the other American national societies, and Past-President Charles T. Main attended as delegate from The American Society of Mechanical Engineers.

During the visit the French Congrès Général du Génie Civil passed a resolution asking the formation of a permanent Franco-American Committee and the French members of such a committee were duly appointed by the Congress, consisting of a general secretary and the presidents of the five committees with whom the members of the American delegation had been coöperating, as follows: Ports and Navigable Waterways; Water Power; Roads; Agricultural Development and Technical Education. To meet the desire of the French engineers the American delegates consented to act temporarily as members of the international committee, and pending action in the matter by the councils of the several American societies.

It is a pleasure to note that a return trip by a delegation of French engineers is expected to occur this month.

The American engineers report a successful and interesting trip and upon their return two meetings were held, one in Boston at which Past-President Main was welcomed and one in New York where addresses were made by several members of the delegation. Reports of these meetings follow, together with the text of a brief address made by Mr. Main at Martigues on the occasion of entertainment by the Chamber of Commerce of Marseilles.

Dinner in Boston for Past-President Main

The January meeting of the Boston Section, which was held at the Engineers' Club, January 31, was devoted to welcoming Past-President Charles T. Main on his return from France in connection with the rehabilitation of that country. Mr. Main was first welcomed at a dinner of about fifty members, after which he addressed an audience of members which filled the auditorium of the Engineers' Club.

The questions which the party of engineers, of which Mr. Main was a member, were asked to consider included commercial ports, water power, roads, technical education, mines, mining and agriculture. Mr. Main covered many phases of the work accomplished by the American engineers, and the following are a few of the points mentioned:

The French engineers are very capable. Their knowledge of theory is perhaps better than ours. Their plans are made very thoroughly; but due to the almost universal lack of standardization, with every man doing his work in his own personal way, the facility with which operations are completed seems relatively slow.

In Paris a munitions works capable of turning out 20,000 shells a day was begun in May 1918 and completed in four months. This plant was of sufficiently substantial construction and was admirably arranged for speed and economy of producing shells. In another place a plant was constructed which at the time of the signing of the armistice was delivering 25 tanks a day.

The coal shortage of France is leading to consideration of hydroelectric development, especially of the waters from the Alps and Pyrenees. This power is being largely used for electrochemical industries and the electrification of railroads is being very seriously considered. The hydraulic turbines which are used are of efficient design and contain wheels similar to those in a steam turbine.

A Franco-American Engineering Committee was formed. The American representatives were asked to serve as members of this Committee, which they agreed to do temporarily until they could report to their different engineering organizations.

A visit of the French engineers to the United States was arranged for March next, when they will study the electrification of railways and visit the larger manufacturers of railway and power-plant apparatus.

The actual damage to France caused by the war has been estimated at about \$14,000,000,000. This is for physical damage only, and does not include consequential damage. This approximate estimate of losses is divided as follows:

For buildings	20,000,000,000 francs
For furniture	5,000,000,000 francs
For grounds, cattle and forests	10,000,000,000 francs
For industry	20,000,000,000 francs
For public works	10,000,000,000 francs

It has been estimated that at least 250,000 buildings were totally destroyed, 250,000 partially destroyed, and at least 250,000 acres of land so devastated as to require restoration.

The French laws are such that an alien cannot hold more than one-third of the capital stock of a French company, which leaves the control in French hands.

Contrasting French technical schools with American schools, the French seemed to require less mechanical equipment; and the actual working out by the student of problems similar to those encountered in the daily practice of engineering, the actual handling of equipment such as electrical machinery and the doing of work on machine tools in the school shops, was much less common than in America.

The ability of the Americans in forcing construction work made an impression on the French, who intimated that some Americans might be desirable as superintendents and foremen in their plants.

The suggestion of the French to improve transportation by the construction of more canals was not favored by the American engineers, because under the average conditions in America railroads have proved more advantageous.

Engineering Problems Connected with Reconstruction

Address By Past-President Main at Martigues, France

We consider it a very great honor and privilege to be allowed to come to France to discuss with you the problems of reconstruction and redevelopment. We have, in our own country, many problems of reconversion from war to peace activities. We were unprepared for war, which was a possibility, and we are unprepared for peace, which is a certainty.

There are now before Congress two bills contemplating the creation of a commission for the discussion of such problems as labor, capital and credit, public utilities, demobilization of industrial and military resources, foreign trade, continuance of existing industries, agriculture, adequate production and effective distribution of coal, gasoline and other fuels, shipping, shipyards, ownership of yards and ships, housing conditions, technical education, the supply, distribution and availability of raw materials and foodstuffs, conservation of natural resources, transportation by rail and water, reorganization of Government bureaus on an economical and efficient peace basis, and consolidation and amendment of acts of Congress.

These are only a repetition of your own problems. In each of the belligerent countries there are the same problems to face, except that you have the additional one of the reconstruction of the devastated territory. We shall be very glad if we can be of any assistance to you in any of these problems.

Nearly all of the problems suggested are directly and indirectly engineering problems, and the assistance of engineers will be

needed now more than ever before, and the engineers should look upon them with a broader vision and should take a more active and helpful attitude toward public affairs and industrial relations which they have considered heretofore beyond the scope of their work.

You have asked us to consider with you the problems of Harbors, Water Powers, Roads and Pavements, Agriculture and Technical Education.

We have visited some of your ports and are very much impressed with the great possibilities of their further development. It would be presumptuous of us to attempt in the short time we have given the subject to say which is the best method of development.

The question of roads and pavements is a more definite one, and our committee has made its report with definite recommendations.

The problems connected with agriculture are so involved in the laws of France that we may not be able to give the advice you desire, but our committee has made a report which may be helpful.

Your technical schools are good, but we think it would be of great benefit to this country if we could have an exchange of professors and some of your professors and students could spend a year in some of our technical schools.

We have seen some of your water-power developments and have had presented to us in detail several projects for the development of hydroelectric power. The possibilities appear to be satisfactory for the development and use of some or all of these, especially when considering the high price and the possible shortage of coal.

The problems of water-power development are the same in all countries, with varying local conditions, and are largely problems in economics. It cannot be expected that private individuals or corporations will invest in enterprises of this sort that do not promise a fair return on the investment. If the cost of construction for a given project is so great that a fair return cannot be earned, it will remain undeveloped, unless the Government assists in financing it. Such assistance would be warranted if in addition to the power generated there were public benefits to be derived, such as prevention or diminution of floods, irrigation, or conservation of fuel, which would preserve for future generations the heritage which properly belongs to them.

Nearly all of the developments in our country use all the flow of the stream for some months in the year, and for the remaining months there is a deficit of water power which is supplied by steam power. The economic limit of development is also one of economics and can be solved within reasonable limits. As the requirements of business grow more exacting, it becomes absolutely necessary to have constant power assured.

In our own country considerable attention is being given to the construction of storage reservoirs, but no great progress has been made in the actual construction of such reservoirs for power purposes only. We have had very little encouragement for water-power development owing to the laws and the attitude of the law makers. A water-power bill is now under discussion in Congress, and it is hoped that a bill will be passed which will be liberal enough to stimulate developments. We were surprised to see in the vicinity of Grenoble two high-head powers, which were originally developed in 1868-1869, thus antedating any of the high-head developments in America.

Transportation problems are getting to be very serious with us. At least one-quarter of the transportation is for the coal used by the railroads. The development of electric transmission of power has made it possible to change many of our previous methods of doing business, and we are now discussing the feasibility of constructing steam plants near the mouth of the mines and at tide-water of larger capacity than have previously been built. We are also considering the further and more efficient development of water power, and the running of great connecting trunk lines for the transmission of electric current and the electrification of the railroads. If these projects could be carried out a large portion of the railroad equipment would be released for other purposes and less coal would be burned.

It appears to us that these are the general lines along which you are proceeding and should proceed with your future developments. The principal projects should be considered together, and the successive developments made as they will best fit into the general plan. Competition may be ruinous, but concerted effort will prove to be successful.

We have been privileged to visit some of the devastated areas and to get a definite idea of the damage done to your country. We cannot express the depth of our sympathy. We can be of some assistance to you in transmitting our impressions first hand to the citizens of our own country.

Our delegation is deeply indebted to you and to every one for the gracious courtesy which has been so uniformly accorded us. We shall carry back to America a memory which will last as long as we live. On behalf of our delegation, I desire to thank you all for these courtesies.

Engineering Delegates Tell of Their Observations Abroad

On February 10 the delegates to the French Engineering Congress presented to a meeting of the four engineering societies, held at New York, an informal report of their trip and of their impressions of engineering conditions in France.

Dr. George F. Swain described the work of the Congress and spoke interestingly of certain aspects of the present situation in France. Speaking of Waterways and Transportation he said in part:

"France has done more than any other country in Europe to develop a system of internal waterways, canals and navigable rivers. All of these are owned and maintained by the government, which has assumed the debt and pays the interest on the debt and maintains the river and canal work. The man who wants to operate a boat on a canal simply buys the boat and operates it; and when one pays for canal transportation he simply pays the boatman his charge, whatever it is.

"The railroads are dominated by the government, but of the seven railroads of France, six are owned by private corporations while the seventh is a state railroad. Even for private corporations the state assumes the risk of all funds for construction. The companies pay all expenses of maintenance and operation. They pay due taxes to the government and they are allowed to earn a dividend for their stock holders which amounted, three years ago, to something over 4 per cent.

"The French have a great idea of developing waterways and the only point in which the members of the delegation were not quite in accord with the French engineers was with regard to their plans for spending large sums of money in building canals and making rivers navigable. Apparently no study was being made of the economics of these questions; no statistics of transportation, no study as to whether they could get any return from the expenditure."

With regard to technical education, one of the subjects investigated, Dr. Swain said:

"I think the French appreciate that with them as with us, the events of the last few years ought to lead to changes in educational methods. It is a great thing to have one nation learn from another and the best time to learn is when a man is young. We emphasized at every opportunity the desirability of having Americans go to France to study and Frenchmen come to America to study.

"Their engineering schools are in the hearts of the cities where they cannot grow, where they have no room for laboratories or any expansion. One of the ministers said they were going to appropriate large sums for technical education, and I think they will. I hope they will open their schools to foreign students without undue petty requirements or restriction and I think there will be, in the future, an interchange of our young men with their young men. I think there is a good prospect of that proceeding."

Mr. George W. Tillson, a civil engineering delegate, gave an account of French plans and methods of road construction. In the course of his remarks he said:

"I, personally, was considerably surprised to find that the

question of roads was one for discussion, because I knew that the French for many years had the reputation of having probably the best system of roads in the world. I was surprised that they should ask this new country of ours for anything in the way of information on that subject, but, when we came to confer with them, it was very simple."

It had been pointed out to the American delegates, however, that the development of motor traffic necessitated new methods of construction and the two methods which seemed to appeal to the French engineers were the construction of asphaltic macadam by the penetration method and by the mixing method.

"We told them," Mr. Tillson said, "of the miles of concrete roads that have been built in this country during the past ten years and the good results that have been obtained and that they could expect better results in France because they did not have the great ranges in temperature which we have here and which cause cracks in the concrete. They were, however, inclined to disapprove of this method because some years ago a concrete road had been unsuccessful, and so without further experiment they had dropped this manner of road building. We urged further experimental work and while our ideas did not appeal very strongly to them, the Congress, nevertheless, agreed to recommend the use of concrete where the materials were so convenient that it would be cheap."

The question of finances as related to road building was of special interest according to Mr. Tillson. American methods would not do, for while they liked the idea of a special assessment, such as we have in this country, and seemed to think that it would be proper that the abutters on the road should pay a certain amount of the cost, under present conditions in France they thought it would be hardly possible to bring it about.

The Mining Engineers were represented by Mr. E. G. Spilsbury, who described a trip to the devastated coal regions of Lens. Before the war this section had 60 mines and 18 were models of mining appliances.

The buildings were all stone or concrete, surrounded with steel structures, washeries and grading machinery with massive steel and concrete storage bins and loading equipment. Of all this nothing remains except tangled masses of broken steel. Not content with letting these structures take their chance of being wrecked by shell fire, the Huns systematically cut the steel supporting legs of the railroad ways and with cables to heavy motor trucks pulled them over. Every hoisting pump and machine was either dynamited or broken up with sledges and every boiler showed signs of having been exploded from the inside, besides the shell perforations in some of the steel domes. The electrical generators and motors had been taken out and presumably shipped to Germany.

The mines were flooded by cutting ditches to some of the shafts and laying pipes to the more distant ones through which they turned the waters of the Somme canal.

It is estimated that it will take 30,000,000 hp. for a year and a half for dewatering. They have a small surface coal deposit about 12 miles from Lens where they are now building a power station from which to run pumps. A thing which was very apparent to the delegates was that the French are not seeking the help of foreign engineers to aid in this work. They have plenty of talent of their own and they are going to use it and use it more or less exclusively.

Hydroelectric developments were discussed by Mr. Lewis B. Stillwell. There is at present, according to Mr. Stillwell, 4,500,000 to 6,000,000 undeveloped horsepower in France, and while our assistance in its development will be welcomed, we can teach the French practically nothing in the technicality of the hydraulic art and the construction of factories. The only matter they may have to learn from us in respect to the work, is that our experience has been on a somewhat larger scale, and with higher pressures. We can, however, assist them in standardizing their plants and systems. Even now, such important factors as frequency and voltage are not standardized, and interconnection, which is so desirable, cannot be accomplished until a standard is universally adopted.

They will also have to carry out the idea of standardization in great detail, if they wish to get the cost of production down to a reasonable basis. At present, the idea of individuality is carried to an extreme that is astonishing to us. The smaller manufacturer who makes a lamp socket, for example, or the retailer who sells the lamp socket will call on the manufacturer to make his a little different from the other kind, on the theory that having obtained his original customers he can hold them as they cannot get that particular type anywhere else.

Other speakers of the evening were Mr. George W. Fuller, who discussed French agriculture and finance; Mr. A. M. Hunt, who outlined the French plans for developing their ports and the proposed east and west railroad to Basle, Switzerland; and Mr. Nelson C. Lewis, who described a trip through the "Smiling Valley of the Marne."

Past-President Charles T. Main, who represented the A.S.M.E. on the delegation, was unable to be present, due to an engagement at Boston.

FUEL PROBLEMS OF THE PACIFIC COAST

The Possibilities of Fuel-Oil Conservation Through Its Economical Use and the Development of Hydraulic Power

In harmony with the spirit of the times, fuel conservation vs. the great demand for power occasioned by our many war industries, was the subject for discussion at a joint meeting of the local sections of the A.S.C.E., A.S.M.E., A.I.M.E., A.I.E.E., and A.C.S. at San Francisco shortly before the signing of the armistice. Although the problems of peace now occupy our minds, we must be governed by realities, and much of the discussion given at that time is pertinent to the reconstruction period through which we are now passing.

In addition to the papers which are abstracted below and which bear directly on the subject indicated in the title, others were presented by Major George F. Sever, U. S. A., Capt. Robert W. Brewer and Prof. Edmund O'Neill, respectively. Major Sever told of the careful study he was making of the electric power situation on the Coast for the Government; Captain Brewer gave particulars regarding the various methods and devices employed in conserving fuel in England; and Professor O'Neill pointed out the numerous ways in which the chemist had been of service in solving problems connected with the economical burning of fuel.

Fuel Conservation

A. E. Schwabacker[1]

In presenting his subject Mr. Schwabacker outlined the plans of the U. S. Fuel Administration for carrying on its important work. He said that America's war needs called for 100,000,000 more tons of coal in 1918 than in 1917, and 200,000,000 tons more than in 1914. This tremendous increased demand had to be met by most intensive work in three directions: increased production, efficient conservation, and a distribution which would insure against lost motion.

While every European country had decreased its coal produc-

[1] U. S. Fuel Administrator for California.

tion since the war began, the United States had increased its output by 50,000,000 tons during the first year of the war; 735,000,000 tons of coal were necessary for our railroads, ships, war industries and people; 100,000,000 tons had to come from the anthracite fields and the remainder of the amount from the bituminous.

In 1917 there were produced about 330,000,000 bbl. of oil, and in 1918 an additional amount of approximately 23,000,000 bbl. was required.

Two limiting factors in the production of coal were labor and transportation. With a decreased labor supply, and increased demand, full production had to be obtained by greater efficiency of mine workers and conservation by industrial and domestic consumers. The Production Bureau of the United States Fuel Administration appointed a special committee at each mine. Three members were chosen by mine operators, and three by the workers. This committee urged miners to work eight hours a day six days a week, to report the number of tons produced, and to discourage shortages of hours or absence from duty.

Before the war the demand for domestic coal during the summer was so light that miners would often seek other occupations. The Fuel Administration encouraged the early buying and storage of coal by patriotic appeals to consumers through a "Buy Early" campaign. This was a tremendous success and kept the demand upon many mines during the summer months up to maximum.

The Fuel Administration created a labor bureau, wherein the matters pertaining to labor in the coal-mining industry remained under the jurisdiction of the United States Fuel Administrator. Strikes in the industry were reduced to a minimum, thanks to the efficient work of this bureau.

A zoning system which eliminated cross-hauling of coal and avoided waste of transportation was estimated to save over 20,000,000 car-miles a year in the movement of coal. A consequent saving of fuel that would otherwise be used in this transportation was also made.

Before the organization of the Fuel Administration shipments of bunker coal to seaports contained as high as 10 per cent of foreign substance. Strict regulations introduced later, however, prohibited the delivery of any coal to Atlantic or Gulf ports for bunkering purposes that was not up to the Fuel Administration's specifications.

Fuel oil also had to be conserved to the utmost for the use of ships. Mr. Rossetter, Director of Operations of the United States Shipping Board, had advised that the emergency fleet could be operated by American seamen in competition with foreign vessels manned by cheap Asiatic labor, providing fuel oil was burned instead of coal.

The speaker said that the experience of H. R. Collins, of the Fuller Engineering Co., with many grades of coal, indicated that every solid carbonaceous fuel from lignite to the graphitic anthracites of Rhode Island, would yield its maximum measure of heat if burned in pulverized form. The cement industry alone, in California, consumed 1,700,000 bbl. of fuel oil per annum. If California low-grade lignites and sub-bituminous coals were pulverized and utilized as fuel to serve this industry, approximately 350,000 tons of coal in the pulverized state would release for ship's use 1,700,000 bbl. of fuel oil.

The Fuel Administration had endeavored to stimulate development of hydroelectric power to serve as a substitute for fuel oil and coal. Central generating stations were recognized to have far greater possibilities for fuel conservation than smaller isolated plants, and the elimination of less efficient plants was being urged.

Interconnection of power companies had been accomplished in many localities through the efforts of the Fuel Administration. Substantial savings of fuel oil and coal had been made possible, particularly in those communities where water-power plants had been interconnected with those operated by steam. By the closing or consolidation of many so-called "less essential" industries, supplies of fuel, raw materials and man power had been made available for war industries.

Lightless nights were estimated to have saved 500,000 tons of coal. Skip-stop systems on street railroads promised to save 3 per cent of fuel consumption and the daylight-saving plan had saved approximately $1\frac{1}{2}$ million tons of coal per annum.

Production of Energy

A. M. Markwart[1]

Mr. Markwart drew attention to the vital importance of developing the water-power resources of the country. Our coal measures, he said, were sufficient for several generations, but production had already reached the point which, with the supply of oil, would answer the most essential needs only if these supplies were guarded by the most careful restrictions as to their use. Naturally, in increasing the supply of energy, we should give some consideration to that form which would best serve our present and future needs.

The production of coal took an enormous amount of man power each year, the value of which was lost after the coal was consumed, and the natural resource was diminished accordingly. This was equally true of oil, whereas the human effort expended on the creation of a hydroelectric plant was much less and it was spent but once; its result was conserved throughout the plant life, and a corresponding amount of wealth was created.

In developing the greatest natural resource of the country—"white coal"—a beginning had barely been made. Here was a practically inexhaustible supply of energy. The undeveloped water power of the nation had been variously estimated at from 55 million commercially to 225 million horsepower theoretically. Accepting the lower estimate it was said that 40 million of this was to be found in 13 western states and mostly under Federal control. Of this there was perhaps 5 million in the state of California, but not over half a million of which had been developed. The total developed water horsepower of the United States was stated to be about $6\frac{1}{2}$ million, and the steam-engine horsepower, including railroad locomotives, 28 million. It was evident that there were great water-power opportunities, many of which were favorably situated for immediate development, to satisfy the needs of a wide and constantly increasing consumption.

The laws under which water power might be utilized, however, were so stringent that there had been a stagnation in water-power development. While in normal times policies were deterrent, in war times they were practically prohibitive, and the obstacles to be encountered were so numerous that corporations could not undertake any kind of expansion whatsoever. To develop a hydroelectric project in California it was necessary to obtain permits from the Forest Service (if public lands were involved), the State Water Commission, the Railroad Commission, the Commissioner of Corporations, and the Fuel Administration; and then, when all of these permits had been obtained, it was necessary to secure a certificate from the Capital Issues Committee that the issuance of the securities in connection with the project was not incompatible with the interests of the United States. And after all this had been done, the War Industries Board, the Railroad Administration and the Selective Service Boards would thus determine respectively whether or not the necessary materials of construction might be obtained, transportation arranged, and men secured to accomplish the physical work. These restrictions were doubtless necessary to safeguard the interests of the public and to maintain the conduct of the war, but they did not facilitate the development of this enormous wealth of potential energy.

It would therefore seem that sane, accelerant effort should be directed toward the utilization of hydroelectric power rather than exclusively toward the exhaustion of coal and oil, with the consequent waste of man power and absorption of transportation facilities. Water power was now locked up by prohibitive restrictions. We should have done with this kind of conservation and should proceed with the development and utilization of this tremendous resource in order to save for posterity some of those non-renewable natural resources upon which this generation was drawing so heavily.

[1] Civil Engineer.

Gas as a Conservation Measure

J. A. Britton[1]

The essential and fundamental elements of conservation are being taught the American people of today, who are rapidly learning their lesson and who patriotically desire to conserve that which the Government requests them to conserve. In reference to the economies of heat, light and power under the conditions of distribution as they exist in the north central part of California, the alternatives for artificial gas are electricity, wood, coal, oil and the residual products of crude oil.

Electricity, while fulfilling every expectation as a means of light and power, has never measured up to the standard of other means for producing heat. Heat generated by means of electric resistance can never be a successful competitor of gas where the materials from which gas is derived are readily obtainable. It is also conceded that the transporting cost of coal and oil from which gas is made, to the point of manufacture, is materially less per heat unit than the cost of conducting electric energy to the point of its conversion into heat. The use of electricity for heating therefore becomes at once an economic waste of material and man power. The same truth would apply to lighting except for the diversified uses of electric energy, its adaptability and the personal care that is necessary in the use of gas and oil.

The lack of a good quality of bituminous coal in California renders its use as a competitor of oil or gas at once out of consideration. When one considers the enormous amount of labor required in the mining, transportation and distribution of coal, and the lack of efficiency in its application to the production of heat, and the necessity for the removal of the residuals of combustion such as clinker and ash it is evident that it may be dismissed from this discussion. The chief consideration can safely be given to the relative merits of oil used directly and of oil transformed into artificial gas by the modern process which is essentially Californian in character.

In the modern process of gas manufacture from crude oil it is safe to estimate that not more than 7 gal. of oil is used, for all purposes, in the production of 1000 cu. ft. of gas having a thermal value of 550 B.t.u. per cu. ft., 70 per cent of which is applied to effective work in modern domestic appliances and more when used in large industrial installations. The distribution of gas requires no transportation or man power nor are these involved in the disposal of residual or by-products. It is available to the smallest consumer as well as the largest and has been a most important factor in war work.

The gas company in delivering gas to the consumer eliminates the coal bin, and provides hauling of material to any waste from the kitchen or factory. A much higher percentage of the total heating value is utilized than in any other form of fuel. The use of gas means conservation of man power. for all equipment is ready and manufacturers and industrials need not stop other important work to supply the needs of gas companies.

Oil-transmission lines deliver the material to the plants and men and transportation facilities are released for other work. Engineers, firemen, laborers, horses and wagons and the minor materials necessary in the operation of small steam plants can be dispensed with if gas is the fuel. Insurance rates are lower, for the fire hazard is reduced to a minimum.

Future Requirements of Oil

D. M. Folsom[2]

No one can measure with any degree of accuracy the quantity of oil under ground and no oil company can ever hope to secure in storage above ground more than a few months' supply of crude oil or any petroleum product. A change in the demand for refined products is immediately reflected in the entire industry. While it was rash to predict the future, the speaker said, he would attempt to point out in a broad way the future requirements of oil on the Pacific and particularly to emphasize the dependency of Pacific industry and commerce upon oil.

If the United States is to meet successfully the industrial and political problems which will arise after the war it must be done through increased domestic development and through the expansion of our foreign commerce. Furthermore, every boat that operates successfully on the Pacific under the American flag must be an oil burner, and eventually these boats will be equipped with internal-combustion Diesel engines. There are two reasons for this. In the first place the coaling stations of the world are under the control of either the English or Japanese nations, but more important than this is the fact that only through the use of oil can America meet the cost of competition under the handicap of the high wages which this country pays its seamen.

Oil is a natural fuel for ships: compared with coal it is cheaper, easier to handle, and more efficient in use. It gives a longer steaming radius to vessels. The amount of oil required to supply our new boats will tax our resources to the utmost. At present we are not producing in this country enough oil to meet our own domestic requirements and the present estimates of the Shipping Board call for an additional eighty million barrels, or 25 per cent of the present production, for the support of the new merchant fleet.

This can only mean one thing—a smaller quantity of oil for use on land. It is inconceivable to us as Americans that our fleet will not be a success, but we will be unable to compete successfully in the commerce of the world unless we provide oil for this fleet by conservation and substituting other fuel or power on land for the fuel oil we are now consuming.

On the Pacific Coast this presents an acute problem worthy of the best talent in the engineering profession. Oil is our best fuel, and California oil supplies two-thirds of the power, light and heat over the western third of the United States.

If we are to expand our own trade and develop products to supply cargoes for our ships, we must have fuel for factories, mines and farms. With the necessity for decreased use of oil, where is the Pacific Coast to get this power? I believe there is no single solution, but instead a joint solution to this problem. Oil must be used more efficiently both on land and on ships through the development and increased use of the internal combustion engines, and on land hydroelectric power must be developed and used on a greater scale than ever before.

Intelligent conservation means efficiency in the use of our fuel—not curtailment that cripples industry. Intelligent conservation also requires development of natural resources now utilized. Regardless of the cost in money or the labor involved, the streams of the Pacific slope must be made productive of power.

This program brings an opportunity to engineers—in fact it brings more than an opportunity—it is an obligation to each society of engineers and each individual to get out of the technical groove and to use imagination, to use initiative, and to think in terms of the future.

Electric Consolidations and Their Relations to Fuel Conservation

H. G. Butler[1]

Since the beginning of the war the Government has gradually eliminated all the more conspicuous forms of waste, and it will be necessary to continue this policy after the war if we are to compete successfully with the industries of Europe, all of which have been speeded up for war production in such a way that the speed can be maintained after peace comes. In France, to cite only one instance, 180,500 hp. has been installed since 1914 on three rivers of the Alps. The magnitude of this development can be appreciated when it is understood that it would carry about 50 per cent of the peak load of all the power plants in the state of California north of Merced.

Production all hinges on power; power reduced to its simplest

[1] Vice-President and General Manager, Pacific Gas and Electric Co.

[2] U. S. Fuel Administration, Oil Division.

[1] Power Administrator.

terms means one of two things, fuel or water. The first step in the program of this country, beyond all question, should be to harness the streams.

There has lately been a move all over the world to interconnect independent power plants in the same locality, and interconnection has been held forth as a panacea for many of the ills to which the electrical industry is heir. The fact that interconnections are being made throughout the United States and other countries indicates that the mutual savings of the interconnected companies are great. They would be much greater, however, if the diverse interests of each company were harmonized and the entire situation in any given territory were handled as a unit. For a supply of 500,000 kw. for war industries in the East it has been estimated that isolated plants, in comparison with central stations, require for installation twice the investment and for operation four times the coal, four times as many coal cars with their complement of locomotives, track and terminal facilities, and four times the man power. Again it has been estimated that if the whole of England were linked up with central stations located at economical points near the coal supplies 50,000,000 tons of coal per annum would be saved.

It is impracticable to attempt to show the actual savings which could be made in fuel by either interconnection or consolidation, because there are many unknown factors in each case and which vary from day to day. Broadly speaking, consolidation would conserve fuel in five ways:

1 It would improve the yearly load factor and the daily load factor because of the greater diversity of load, thus increasing the efficiency of the steam plants; instances of which are the consolidation or interconnection of two companies, one having a large lighting load in the winter and the other a large irrigation load in the summer, or of two companies, one having an industrial load and the other a street-railroad load.

2 In the case of companies having both water- and steam-power plants, the combined operation of water-power plants of different physical characteristics, as for instance a plant with natural stream flow but without storage and a plant with a large forebay, would permit the carrying of peak loads by water power which, without combination, would necessarily be handled to a large extent by steam by the company having the natural stream flow developments.

3 It would permit the load to be blocked out to the more efficient steam plants, so that the less efficient plants would operate only on the peaks or would shut down if the combination had excess generating capacity.

4 In making extensions the combined companies would install larger and more efficient units than the several constituent companies, if each company should make its own extension. In the larger plant higher-class boiler-room supervision would result in fuel economies.

5 Under consolidation existing plants would be enlarged and new plants would be built in locations better adapted to handle the consolidated load, thereby saving fuel through reduced line losses.

As a by-product of consolidation, the loads which could be safely allotted to a certain generating equipment are materially increased and it would be feasible to apply to regular service a large portion of that generating capacity of the companies which would be otherwise held in reserve, because the interconnected transmission lines would make the reserve capacity of any one division available for the whole consolidated system.

In several of these instances it is possible that the mutual benefit to the interconnected companies would lead them to operate their plants to effect these economies; but in many cases commercial, legal and other reasons would interpose objections to the use of the plants in this manner, which could be overcome only by consolidation.

The economies effected in the use of fuel are only one phase of the whole question of consolidation. Consolidation results in saving man power, in conserving capital and in reducing operating expenses; but perhaps after all the greatest gain would be found in the fact that under consolidation the problems which arise in the territory of the consolidated companies would be approached and solved with a mind single to giving the best service for the least cost. Consolidation does not necessarily mean government or state ownership. Until the means of transmission shall have been improved the problems of the electrical utilities in each locality must be solved locally, and in no section of the country is the industry of such magnitude that it cannot be organized and managed by private capital. So many of the motives which urge men to put forth the best that is in them are lost under government ownership that it should be resorted to only after everything else has been tried and has failed. Some way surely can be found to secure both the benefits of consolidation and of private enterprise. Possibly the ultimate solution of the matter will be found in some partnership arrangement whereby the state or nation will do more than regulate but less than own and operate the electric utilities.

Sources of Energy Supply

P. M. Downing[1]

The development of the art of transmitting electric energy long distances has made possible the development of many water powers remote from suitable manufactures or railroad centers, and has been of particular importance in California where there is an abundance of potential water power and a dearth of fuel.

Water-power development in this state has been about equally divided between the northern and southern portions. In 1900 the aggregate installed capacity of all of the plants in the northern part was approximately 15,000 kw. In 18 years this has increased to over 375,000 kw., or at the rate of over 20,000 kw. per year. In addition to this there are also installed steam-generating plants having an aggregate capacity of approximately 187,500 kw., and yet with all of this development California is today facing one of the most serious power shortages in its history. In 1917 the five large power companies in the northern part of the state generated 1,507,000,000 kw-hr. Approximately 16 per cent of this was produced on steam, requiring 1,195,000 bbl. of oil. The peak load during the year was 265,000 kw. The load, both energy and peak demand, is increasing at the rate of 10 per cent per year. To meet this increase there will have to be provided each year additional facilities having an energy-producing capacity of not less than 150,000,000 kw-hr. and a peak capacity of not less than 26,500 kw.

The winter of 1917-18 was one of abnormally low precipitation. Without the usual late storms during the past spring, the stream flows during recent months have established new minimums. The steam plants which heretofore have always been considered as reserves to be used only in emergencies, have been called upon to operate up to their maximum capacity throughout the entire 24 hours of the day. During the past few months approximately 40 per cent of the energy supplied in the northern part of the state has been produced on steam, 40 per cent from stored water, and 20 per cent from natural stream flows.

A forecast of the future is not so bright. The only additional energy that will be available other than that due to a more nearly normal season, is 60,000,000 kw-hr. from the systems of the California Oregon Power Co. and the Northern California Power Co., and an additional 75,000,000 to 100,000,000 kw-hr. from the increased steam plants of the Pacific Gas & Electric Co. On the basis of an annual increase in load amounting to 150,000,000 kw.-hr., this additional energy, even with normal water conditions, will hardly be sufficient to carry the load through the year 1919.

Unless other facilities are obtainable by 1920 there will be a more serious shortage beginning with that year, which will be cumulative until other facilities are provided. No new hydro developments are under way at the present time, and in view of the scarcity of labor and material no new installation of any size can be made in less than two years. Without additional hydroelectric power to relieve the situation, there will be required for steam generation by 1920 between 3,000,000 and 3,500,000 bbl. of fuel oil—an increase of between 500,000 and 700,000 bbl. per year.

[1] Chief Engineer Electrical Department, Pacific Gas & Electric Co.

District Steam Heating as Related to Fuel Conservation

H. S. Markey[1]

District steam heating affords a means for the conservation of fuel. The records of district steam heating over an area of approximately 56 city blocks in the business, hotel and apartment-house districts of San Francisco, and operated in conjunction with a main steam-electric generating station, show, for example, a considerable saving.

The steam is supplied from two well-equipped and efficiently-operated central stations and is delivered through underground pipes. Such a system should be economical in the use of fuel oil, especially if turbo-generators are interposed between the boilers and the consumers, because electric energy so generated reduces the load on the main steam-electric generating stations.

The fuel burned in the stations during the twelve months ending with August 31, 1918, amounted to 129,893 bbl. Maximum and minimum months were January (16,043 bbl.) and August (7102 bbl.).

During the same twelve months the stations produced 6,411,990 kw-hr. Maximum and minimum months were January (947,030 kw-hr.) and August (319,590 kw-hr.). In addition to the electric energy some power is developed in a pair of large steam-driven elevator pumps, but as this power would have to be estimated, no account is taken of it in the records. A comparatively small number of consumers who are not within reach of the exhaust mains are served from a high-pressure main with steam direct from the boilers.

Because of the electricity generated the district steam system is credited with fuel, the exact amount of which can be determined only from thermodynamic considerations. An allowance which is practically correct can be made as follows: The use of steam turbines in the line increases the fuel consumption by 8 per cent or 10,340 bbl. per year. The main station generates from 80 to 240 kw-hr. per barrel, depending on the load, the average for the twelve months being 195.2. The electricity generated at the steam stations, therefore, reduced the year's consumption of fuel at the main station by 32,900 barrels. The difference, 22,510 barrels, was actually saved. This amounts to one barrel for each 285 kw-hr. generated at the steam stations. The high efficiency of the steam-heat stations is due, of course, to the fact that the heat contained in the exhaust from the turbines is not rejected to a condenser or the atmosphere.

The steam-heat stations are therefore to be credited with 22,510 bbl. for the 12-month period, 3325 bbl. for January and 1120 bbl. for August, leaving 107,383, 12,718 and 5982 bbl. chargeable to steam heat for the year, for January and for August, respectively.

The steam delivered to consumers is all metered with the exception of about 5 per cent, which is used in open-jet apparatus and which must be estimated for each consumer using such apparatus. This estimated quantity is added to the registration of the consumer's meter each month. Including the open-jet steam there was delivered to the consumers during the 12-month period 306,978,000 lb. of steam, and during January and August 41,609,000 lb. and 14,914,000 lb. respectively.

The steam is supplied to the consumers at an average pressure of 5 lb., and by the steam tables each pound carries 1156 heat units above 32 deg. fahr. The condensate leaves the premises at a temperature of from 100 deg. to 180 deg. fahr. above 32 deg. To get an even figure assume 156 deg. as an average. Then each pound of steam passing through the premises leaves behind it 1000 heat units. This is the difference between heat put in and heat rejected and is therefore the useful heat delivered to the consumer.

The useful heat delivered to the consumer per barrel of fuel, works out as follows:

For the 12-month period	2,860,000 units
For January	3,270,000 units
For August	2,500,000 units

[1] Engineer, City Electric Co., San Francisco.

Assuming 6,000,000 units as the heat value of a barrel of oil, the overall efficiency is:

For 12 months	48 per cent
For January	55 per cent
For August	42 per cent

The variation in the demand for steam is such that for three or four months the larger of the steam-heat stations is not operated and for about two months during the winter both are needed. This condition affects the efficiency unfavorably.

Fuel would be still further conserved if there were twice as many consumers connected to this system so that its efficiency would be maintained the year round. During the winter peaks additional steam could be supplied direct from boilers held in reserve for that purpose. The amount of fuel burned under these boilers for a month or two would be small compared to the saving effected at the main steam-electric generating stations in a year.

Railroad Electrification as a Fuel-Conservation Measure

W. J. Davis, Jr.[1]

In making a study of the possibilities of conserving our available supply of fuel through the electrification of the railroad systems of the United States, there are two points from which the subject may be viewed:

1 The possible saving that may be effected by the replacement of the steam-locomotive equipment now in use with electric locomotives supplied with power from modern steam-electric generating plants of large capacity, suitably located with regard to cheap fuel and water and distributing over large areas through high-voltage transmission systems.

2 Saving to be expected by comparing the possible performances of modern compound steam locomotives using high superheat with a system of electrification and power supply as above described.

Basing calculations on pre-war conditions, it is found from the Reports of the Interstate Commerce Commission that the total gross ton-mileage movements of the railroads in the United States for the year 1914 were approximately as follows:

	Ton-Miles	Per Cent of Total
1 Bituminous coal	166,400,000,000	15.93
2 Anthracite coal	38,200,000,000	3.66
3 Railway-company coal	57,600,000,000	5.51
4 Miscellaneous freight	372,040,000,000	35.65
5 Locomotives	148,200,000,000	14.20
6 Locomotive tenders	74,630,000,000	7.15
7 Passenger cars	186,890,000,000	17.90
Total	1,043,960,000,000	100.00

In estimating the gross freight-ton mileage it has been assumed that the net ton-mile movement of the freight alone will be approximately equal to that of the cars. This assumption applies of course only to the first four items.

Assuming that the complete electrification of the railroads is feasible and desirable, it is at once apparent that a considerable saving may be made in the total ton-mileage shown above. In the third item of the table, railway-company coal, the ton-mile movement may be reduced to about one-third by the greater economy of electric power generation and a still further reduction will follow due to the location of many of the central power plants near the mines and to the use of such hydroelectric power as may be available. It would appear fair to assume, therefore, that the ton-mileage now required for the movement of railway company coal may be reduced to about 25 per cent of item 3, or 14,400,000,000 ton-miles. The saving in this item would be approximately 43,200,000,000 ton-miles or 4.15 per cent of the total.

[1] Engineer, General Electric Co., San Francisco.

The sixth item, ton-mile movement of locomotive tenders, may be eliminated completely, making a possible reduction of 74,630,000,000 ton-miles or 7.15 per cent of the total by the use of electric locomotives. We therefore find that the total ton-mile movement of all of the railroads in the year 1914 would have been approximately 926,130,000,000 if all of the roads were electrified, a saving of 11 per cent.

In estimating the fuel consumption of the electric power plants required for the above movement, we can take as a basis for our calculations the results of some tests made on the Chicago, Milwaukee & Puget Sound Railroad, between Three Forks and Colorado Junction. The net energy consumption in a round trip over this section of heavy grades and curvature, using regenerative braking, was 23.75 watt-hours per ton-mile at the locomotive, including power required for all of the auxiliary apparatus. The energy consumption of the same train on level track of the same curvature as determined from the known train weights, profile and locomotive efficiency, was found to be 20.4 watt-hours per ton-mile. These results are of particular interest as they show that with electric locomotives and regenerative braking it is possible to eliminate a large proportion of mountain grades in so far as they affect the power required for moving the trains.

It will be seen from the above that highly efficient compound non-condensing steam locomotives of modern type operating in railway service as it exists today would be expected to use more than 2.5 times as much fuel as is required by an equivalent electric system. If we assume the total fuel requirements of the two systems to be in the ratio of the estimated economies shown above with allowance for reduced ton-mileage of items 3 and 6 in the ton-mileage table, the saving in fuel on this basis for 1914 would be 79,400,000 tons.

In our final consideration of the possibilities of fuel conservation by electrification of the railroads, we must not overlook the fact that in large steam-power plants it is feasible and often economical to burn low-grade coals, whereas the steam locomotives require the higher grades of selected lump coal. This will release a large part of our highest-grade fuel which may be applied to our growing merchant-marine demands and to household uses.

Assuming a transmission efficiency of 72 per cent from the power-station bus bars to the collectors of the locomotive, the energy consumption at the power house, using the larger test result as a basis for calculations, is found to be 33 watt-hours per ton-mile.

Assuming then a total ton-mile movement of 926,130,000,000, the energy consumption required by complete electrification would be 30,500,000,000 kw-hr., to which should be added 20 per cent for shifting and yard movements and additional requirements of suburban passenger service, making 36,600,000,000 kw-hr. as the total energy consumption for the completely electrified system. On the basis of an operating economy of 1.84 lb. of coal per kw-hr., the annual fuel requirements for electrification would be 33,700,000 tons of coal. As the actual amount of coal consumed by the railroads in 1914 for locomotive use alone, including an allowance for fuel oil on the basis of 4 bbl. of oil per ton of coal, has been found to be approximately 120,000,000 tons, the total saving to be expected in case of complete electrification would be 86,300,000 tons. This is about one-sixth of the total coal production of the United States.

The point may be raised that the above calculations are hardly fair to the steam locomotive as we are comparing a highly efficient modern electric-generating system with a variety of steam locomotives, many of them of old and inefficient types, and that modern compound steam locomotives using high steam pressures and high superheats might accomplish almost as great a saving as would be obtained by electric haulage. That this can not be true is due to a number of factors inherent to the two systems. The effect of these factors may be seen from the following tabulated calculations in which the economy of a large turbo-generator station operating under steam conditions demonstrated to be

(Concluded on page 292)

DAVID MOFFAT MYERS ON FUEL CONSERVATION

At the Refrigeration Session of the Annual Meeting in December, David Moffat Myers, Advisory Engineer of the U. S. Fuel Administration, discussed in a brief address the engineer's part in carrying out the object of the United States Fuel Administration, which was to obtain the fuel required for conducting the war. He said when he went to Washington a year earlier he found that the only kind of conservation practiced was saving by curtailment. When, however, the four national engineering societies had appointed a committee, of which Professor Breckenridge was chairman, that coöperated with the Bureau of Mines and some officers of the Fuel Administration, a plan of action was adopted which solved the problem of fuel shortage with least inconvenience to all concerned. The guiding motive was "maximum production with minimum waste." Instead of saving coal by shutting down factories, they were kept going at higher efficiency, so that a saving of 10 to 25 per cent was made in their coal consumption, a saving which, during the first six months of this program, starting May 1, 1918, was equivalent to 7,000,000 tons of coal per annum from the power plants alone, plus 5,000,000 tons saved in other directions.

During 1918 a force of 1500 volunteer engineers, including a large representation of The American Society of Mechanical Engineers, gave their efforts to the work of inspecting and advising power-plant operators in the economical generation of steam and power. The demand for coal increased so rapidly during the war that by the end of 1918 the United States would have produced and distributed 100,000,000 tons of coal more than during the year 1916.

Mr. Myers then described how the Fuel Administration proceeded to enlist the coöperation of industrial plants. It was recognized that during the war there was little opportunity for improving the existing equipment of plants, but it was entirely feasible by education to impress upon the operators the necessity for fuel conservation and the means available for effecting it. In addition to personal visits by the representatives of the Fuel Administration, lectures were arranged to reach a large audience. At such lectures a number of lantern slides were made use of, which served to bring out in a simple manner the several fundamental rules to be observed in the economical operation of steam and power plants. Reports received at Washington served to prove that the entire campaign was very successful in both small and large power plants. These slides were also exhibited at this meeting and explained by Mr. Myers.

The speaker further related how in the beginning of the work failure had been predicted because of the attempt of the fuel engineers to go into a man's plant with the intention of telling him what to do. It was decried as paternalism. But the results showed that with the possible exception of one, all of the states endorsed the procedure of the administrative engineers; and directly after the signing of the armistice, when there was talk of the dissolution of the Fuel Administration, requests poured in from all parts of the country to continue the good work. In reply to these requests a conference was held early in December 1918, attended by Van. H. Manning, Director of the United States Bureau of Mines, Dr. Otis Smith, Director of the United States Geological Survey, and Dr. H. A. Garfield, United States Fuel Administrator, at which it was decided to merge some departments of the Fuel Administration into the other two Government departments named. For example, the work of the Conservation Bureau as well as the engineering program would be taken over by the Bureau of Mines. In conclusion Mr. Myers asked the engineers present to continue to loyally support the conservation movement until the new organization was ready to relieve them of this work.

At this session, which was held jointly with the American Society of Refrigerating Engineers and presided over by Dr. D. S. Jacobus, two papers were also presented: namely, The Development of a Standard Refrigerator Car, by Dr. Mary E. Pennington, of the Food Research Laboratory, U. S. Department of Agriculture; and Refrigerating Plant Efficiency, by Victor J. Azbe.

Chairman Jacobus in opening the discussion inquired of Mr. Myers whether in his opinion the excellent results achieved in war time were likely to continue after peace had been declared, when one of the actuating motives, namely, patriotism, would not be as strong as during the war. He further would like to know whether, in Mr. Myers' opinion, the power given the Fuel Administration to cut off the fuel supply in case there was undue waste, which was not corrected, had any important influence. Mr. Myers responded that in no case had it become necessary to actually cut off the supply because the idea of conservation had met with widespread favor, and he believed that the good results would be likely to continue if means were provided for properly carrying on the movement after the war.

plant with the object of improving it to earn a fee. From the speaker's sad experience he feared that hereafter the operating engineer, especially in a small plant, would have the same difficulty as formerly in convincing the management that he should be supplied with the equipment and instruments required for economical operation.

Joseph Harrington, Fuel Administrative Engineer for Illinois, at the suggestion of Harold Almert, described a chemical method of removing soot from boiler tubes which, he declared, was very effective. It consisted simply in throwing coarse salt upon the incandescent bed of clean fuel once every day. This would fill the furnace with dense white fumes, chlorine gas, which would attack and loosen the soot, whether it was a boiler or a domestic furnace,

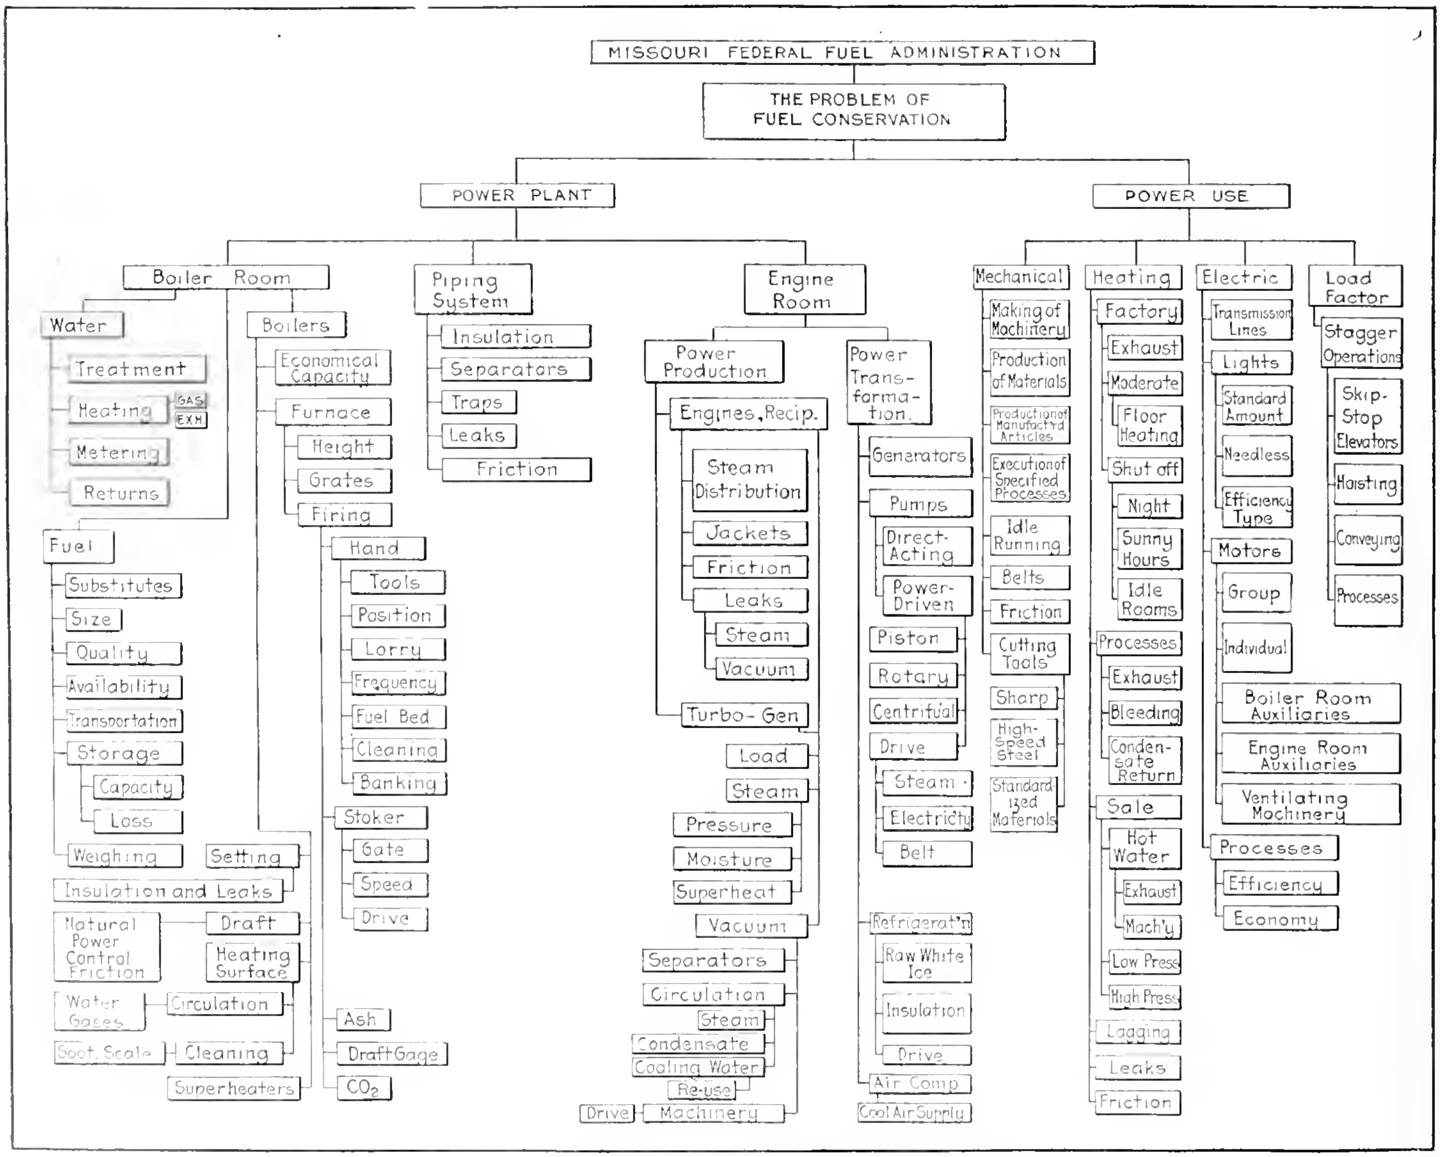

Fig. 1 Problem Chart Used by Fuel Administration in Missouri

Edward N. Trump thought it a good plan to have every plant in the country fill out the questionnaires and have the statistics thus obtained tabulated; the Bureau of Mines could then step in where required and encourage the saving of fuel.

Edgar G. Scott felt that a great deal of the success of the fuel-conservation plan was due to the fact that it reached the owners and managers of plants who ordinarily paid little attention to their cost of power because it represented only a small percentage of the cost of doing business. No doubt the presidents of companies realized that the best engineering skill was behind the questionnaires, and that the force of the national engineering societies supported the cause. Hence their attitude was more friendly than in the case of a single engineer coming into their

and whether hard or soft coal was burned. The soot greatly interfered with the rapid transmission of heat, and it was therefore important to remove this obstacle to fuel economy. A pound or two applied once or twice a week would keep a domestic furnace in good condition. In the case of a 300-hp. Stirling boiler, equipped with Green chain grate, burning Illinois coal, five ordinary coal scoops of salt were being introduced, one at a time. It took about half an hour for each scoopful to disappear. It might take half a day to thus clean a dirty boiler, but if this treatment was applied every day or two, the boiler would always be clean. After two years no sign of corrosion or deterioration of the brickwork would be detected.

Mr. Myers estimated from the results of an accurate test made

two years ago on a 5000-hp. boiler installation in a steel mill that even with the periodical manual removal of soot once every three days, the soot increased the coal consumption on the average by 6 per cent.

THE FUEL ADMINISTRATION IN MISSOURI

THE very thorough manner in which the work of the Fuel Administration, outlined above by Mr. David Moffat Myers, has been conducted in the various states and districts throughout the country, is well illustrated by the following account of the Fuel Administration movement as carried out in Missouri and particularly in one district of that state. The information was supplied through the courtesy of Prof. H. Wade Hibbard,[1] Mem. Am.Soc.M.E., District Engineer in the Fuel Administration of Missouri. Accompanying it were the problem chart shown in Fig. 1 (p. 270) and the district organization chart shown in Fig. 2. These were presented by Professor Hibbard at an early fall meeting of the state and district officers of the Coal Conservation Section of the Fuel Administration.

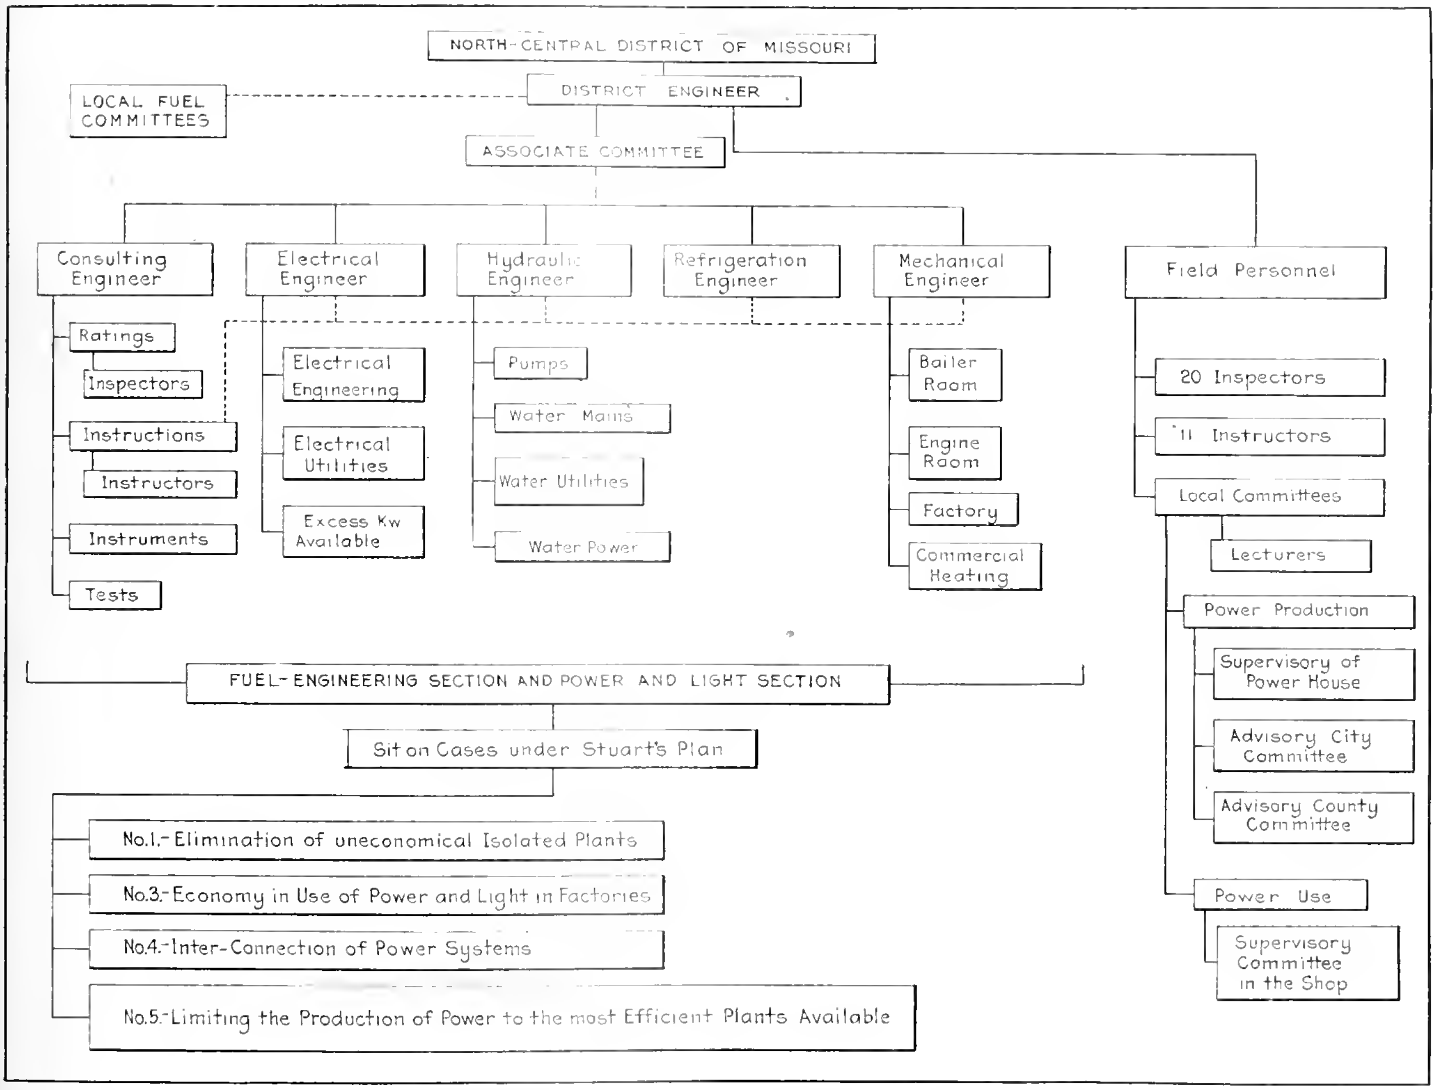

FIG. 2 ORGANIZATION CHART USED BY FUEL ADMINISTRATION IN MISSOURI

ORGANIZATION AND CONDITIONS IN THE STATE

The work of fuel conservation in power plants and factories was being successfully carried out over a very large area of the United States in the second year of the war. The Coal Conservation Section of the United States Fuel Administration, although centrally administered, permitted autonomy as regards organization within the different states. The centralization or distribution of power plants in a state, its topographical divisions, the availability and concentration of Engineers suited for the work—all had their influence in determining the form of a state's organization.

In Missouri the State Administrative Engineer is Mr. J. A. Whitlow, Mem.Am.Soc.M.E., an engineer in the Public Service Commission which patriotically permitted him to devote his entire time to this work. His office was already located in Jefferson City, the capital, and at the geographical center of the state. Under him there are eleven District Engineers, each also already located within his district, and serving without pay.

The state is almost square, measuring 314 miles by 353 miles. It has two large manufacturing cities, St. Louis and Kansas City, respectively, in its extreme east and west, with many small cities scattered over its rich agricultural northern half, separated by the great barrier of the Missouri River from a more sparsely settled southern half, broken up by the Ozark mountain region. In the southwest there is a populous mining district and along the Mississippi and Missouri Rivers are numerous cities of moderate size. These features indicated a suitable division of the state, and also produced variations of organization among the Districts.

PROBLEM CHART

The purpose of this chart (Fig. 1) is to show in classified graphical form the items in power plant and factory affecting the use of coal, with their interrelationships. The chart serves as a guide to office and field work, and eventually would have

[1] Prof. Mech. Engrg., University of Missouri, Columbia, Mo.

been placed in the hands of every inspector and instructor, and posted in each power house and factory.

In its Power Plant Section this chart bears some resemblance to that used by a power-plant designer, but it will be noticed that a great number of items are omitted which such a designer would use. His need is for a statement of the inter-relations of every piece of machinery, equipment and apparatus which by any possibility could enter into his design, while this chart considers that subject purely from the viewpoint of coal saving.

A similar comment should be made regarding the Power Use Section. Naturally the details of every industry could not be included in such a published chart, but only the more general features common to a large number of industries in the state. The Committee on Power Use, mentioned in the Organization Chart in Fig. 2 as in each factory, would work out the additional items for its own chart along the lines suggested here. This local work would be under the help and guidance of the visiting instructor and the engineers of the Fuel Administration.

Organization Chart

The chart in Fig. 2 gives the organization as developed in the district of which Professor Hibbard had charge. The office was at Columbia, thus permitting the use of the volunteer work of a number of men connected with the School of Engineering and the power plant of the University. The local fuel committees had been previously appointed by the state fuel administration, headed by Lieutenant-Governor Crossley, and were at the county seats which are the chief centers of population and industry in the eighteen counties of the district. These committees had charge of fuel requirements, production and distribution, and were naturally closely interested in this work of fuel conservation.

Quite different from the practice followed in some neighboring states, this district made use of inspectors and instructors living in different parts of the district. In the summer of 1918 the District Engineer visited every important power plant, and from their chief engineers selected the best for his purpose. Several men were traveling engineers of pumping stations for oil pipe lines or connected with railways. Some were general managers of power plants with engineering education. Where desirable, employers were interviewed and gave hearty and patriotic consent that their subordinates should devote part time to this work. In a district where the power plants are scattered over an area of 140 by 133 miles, it seemed impossible to carry on this work of inspection and instruction thoroughly and efficiently by men located in one city, even though the men were available, as they were not. As the work was entirely without salary the men could not be expected to be away from home for considerable periods.

Large-scale maps were used showing each man's territory, cities and their data, with railroads and time tables and some automobile routes; charts with power plants under each man, with dates of assignments and visits; 10 by 12 card indexes of each town and its factories, with all names, facts, characteristics and other desirable data; maps for routing of lecturers and films; "tickler" indexes for keeping track of the work; and other time-saving devices familiar to the organizing and management engineer.

Under Field Personnel and Local Committees in Fig. 2 will be noticed the Advisory City Committee. These committees are made up of owners and chief engineers of all the plants in the city, with the leading chief engineer as chairman, unless an inspector or instructor resides there. Local enthusiasm is thus intensified, and the smaller chief engineers get the benefit of advice from their more expert associates.

"Send a Miner Substitute to Pershing" was the slogan adopted and spread among all the power plants of the district. They all knew that the general was born at Laclede in the district. In the Civil War a drafted man could send a substitute in his place. In the present war men beyond draft age, or rejected or deferred because indispensable, were as intensely patriotic as those who went. They enthusiastically took up the slogan in fuel conservation. Any man who was the means of saving one coal-miner's annual output thereby released that man to carry a rifle in France or drive a ship rivet or make a shell. So if owners and engineers and firemen and shopmen could send their "miner substitutes" to establish freedom and liberty in the world, they were exceedingly glad to do so. Coöperation with the Fuel Administration became an easy task; they were not only waiting but aching "to be shown" how they could help.

Those whose hearts have been in this conservation work of the United States Fuel Administration hope that this most widespread university or engineering-extension scheme will in some form be continued by the Government, that the new efficiency, the management engineering in power plants, may carry on its far-reaching education and save human effort in a fundamental industry supporting all the industries.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of Mechanical Engineering by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in this journal, or brief articles of current interest to mechanical engineers.

Proposed Modified Form of Screw Thread as an International Standard

To the Editor:

Numerous commentaries have been written upon the advantages of standardization of engineering productions for use in this country. Now the theme has grown, until today the topic is International Standardization and the question becomes one involving consideration of manufacture in all countries; also of what changes may be made without disrupting business.

Those versed in screw-thread matters have from time to time expressed themselves regarding the shortcomings of the Sellers or U. S. Standard form of thread, particularly in the finer pitches. Among those that have so expressed themselves are Messrs. L. D. Burlingame, Ellwood Burdsall, E. H. Ehrman, F. O. Wells and E. T. Bysshe. The consensus of opinion has been that the crests and roots of screw threads should be flatted to a greater extent than in the U. S. standard thread.

Suggestions have been made for a thread form flatted more than the U. S. Standard thread which might serve as a basis for an international standardized screw thread. Figs. 1 and 2 show respectively the suggestions of Mr. Burdsall and of Messrs. Bysshe and Ehrman.

The diagrams suggested are basic and do not include such details as crest or root clearance, depth of engagement, etc. They lend themselves well, however, to the application of liberal clearance and tolerance without reducing the depth of engagement below that in some of the existing standard profiles.

Assuming a standard pitch, it appears that the following conditions must be met:

A standard thread profile must be

1 No greater in depth than the shallowest existing thread
2 Equal or greater in depth of engagement than the least depth obtainable in any of the existing threads
3 With crest or root clearance sufficient to provide for tool wear in manufacture, and for service

4 Equal to or better than existing profiles in withstanding mistreatment
5 Such as to permit a latitude in the shape of the tool crest
6 No more difficult of production in respect to tools, gages, or product than in any of the present systems
7 With pitch diameter no less than any existing thread profile
8 With elements of thread profile the same; or if there are differences they must be within the commercial tolerance allowed, if internationalism is to be considered
9 With strength of screw equal to or greater than in prevailing systems.

Having in view these axioms, we must consider the principal systems now in use. There are the U. S. Standard and Whitworth systems, both of which have admitted disadvantages, of which the following are the most prominent:

a U. S. S. Root: This is admitted to be too narrow, especially in the finer pitches, and the truncation triangle too small (1) to secure a stable crest in the tool, or (2) to obtain adequate root clearance in the product.

b Whitworth Crest: The depth of engagement is needlessly reduced by at least 0.9 of the height of the rounded crest.

c Whitworth Crest: The apparent advantage of the rounded crest to withstand marring in handling is offset by the difficulty (1) to accurately produce it in the tool and gage, and in the product; (2) to vary it sufficiently to provide adequate clearance, or even necessary tolerance without reducing the depth of thread bearing in a greater ratio.

d Whitworth Angle: An angle of 55 deg. is more difficult to reproduce than the U. S. S. 60-deg. angle.

e U. S. S. Crest: While this crest may not hold its theoretical shape in the tool as well as does the Whitworth crest, the cause may not be due entirely to profile; in all probability it is due partly to its relative narrowness. On the other hand its production, both in the tool product and the gage, is attained and maintained with much greater facility than is the shape of the Whitworth crest.

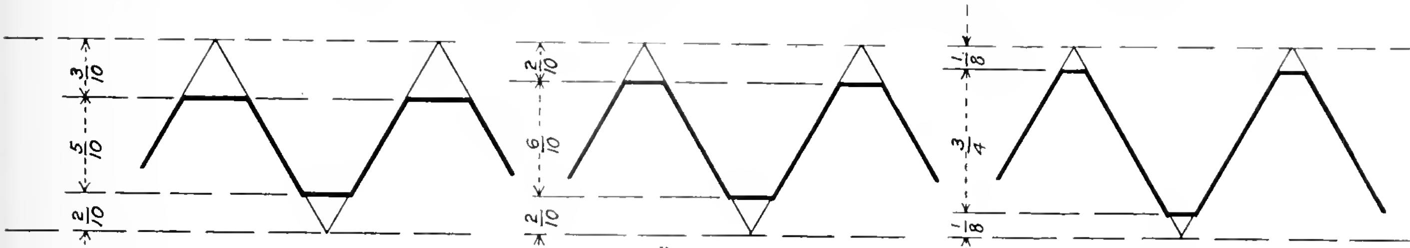

FIG. 1. Suggested by E. Burdsall.

FIG. 2. Suggested by Ernest T. Bysshe and Edwin H Ehrman.

FIG. 3. U.S. Standard. Present.

The modified form of thread suggested by Mr. Burdsall has an increased area of 17, 19 and 24 per cent, respectively, for $\frac{1}{4}$-in., $\frac{3}{8}$-in. and $\frac{1}{2}$-in. bolts, and under test has shown an increased strength at root varying between 11 and 12 per cent. None of these bolts failed by stripping.

The form of screw thread used on the well-known Liberty engine furnishes an excellent example of the possibilities and advantages that are to be gained through a greater truncation than that which obtains in the U. S. Standard thread.

At a meeting of the Gage Committee of the British Engineering Standards Association in September, 1917, a modified form of thread was proposed having the thread truncated slightly at the crest and slightly deepened at the root, the angle of thread and the effective diameter to remain the same. Arrangements were made with a few manufacturers to make sample screws of this modified form of different metals and forward a report.

Owing to the fact that the British manufacturers were then in the stress of high production, a thorough trial was not possible, and the Committee, as a result of the reports received, made the following recommendations:

It was considered undesirable to recommend to the Designs Department the adoption of this flattened form of thread as a compulsory measure, but that tolerance of large amount might be given at crest and root. (See C. L. 4102, British Engineering Standards Association.)

All authorities have agreed that the condition governing the fit of a screw is that the engagement must be as much as possible on the side of the thread, and that the crest and root must clear.

Experience has shown that the sharp "V" thread is impossible to produce because the point of the tool wears so rapidly, producing a screw which will only interchange with difficulty.

The U. S. Standard and Whitworth threads are modifications of the sharp "V" and overcame the low-production manufacturing difficulties of the day now past.

In this communication it has been shown that engineers in widely separated localities have developed independently the same idea, and the feasibility of the features mentioned has been demonstrated by the Liberty engine. Therefore, is it not possible that the proposed modified screw thread contains the fundamental characteristics for modern large-production manufacture and for international agreement?

Great progress in individual standardization of screw threads has been made by the manufacturing countries of the world, but the master mind always considers the future and introduces these questions:

1 Has the best form of screw thread been adopted?
2 When definitely promulgating standards, should other manufacturing countries be considered?
3 After the recent stress of high production, can we complacently look on and consider the science of perfectly manufacturing screws to be thoroughly understood, and further progress impossible?

It seems illogical to suppose that the modern engineer will answer affirmatively to the first and third questions.

The National Screw Thread Commission is about to publish a tentative report, with recommendations on Screw Thread Form, Pitches, Classification and Gaging. This report considers only the form of thread in use in the United States, but since it is but a tentative report, the merits of a modified form of thread may be considered, and the door to international standardization not be closed.

Robt. Lacy,
Lieut. Engrs., U. S. A.

Washington, D. C.

Marine Practice in Valves and Fittings

To the Editor.

Professor Christie's paper in Mechanical Engineering for February, on the state of shipbuilding standards, is particularly opportune, coming at a time when the experiences of manufacturers and shipbuilders alike have pointed out the great hindrance to production occasioned by insufficiently or improperly standardized equipment.

Standards. About three years ago the writer questioned an experienced naval constructor as to why the A. S. M. E. standards in flanges and fittings had never been adopted by the Navy, and was informed that the requirements necessitated the use of stronger materials in order to cut down the weights. This would indicate a tendency to ultra-conservatism among shipbuilders rather than dependence on facts and logic.

The weight of piping in a ship probably never reaches five per

cent of the total weight, and any increase in weight due to the adoption of standard dimensions and materials would be measurable in hundredths of a per cent. A striking example of the need for standards is found in the case of brass and copper tubing. Almost without exception in the trade, brass and copper tubing is made in standard O. D. sizes, yet shipbuilding orders are for the most part specified by I. D. sizes; and the writer has found the use of 12 or 13 different gages on *each size* of tubing between $1\frac{1}{2}$ in. I. D. and 5 in. I. D. Such a condition is not merely uneconomical; it is ridiculous. Many times orders from the same yard differ by one or two thousandths of an inch for the same I. D. sizes, and in many cases the gage is expressed in ten-thousandths. Very likely this last is chiefly due to some conscientious but recent technical graduate. No doubt there is good reason to save money on this expensive material by keeping down thickness, but certainly three to four gages in each size would entirely cover the requirements, especially since the stresses involved in piping under temperature variations are so nearly indeterminate. Most of the failures in piping have been due, not to bursting stress, but to abuse in erection, water hammer, and insufficient provision for expansion.

The objections to copper piping are the expense, both for material and fabrication; low tensile strength; and unsuitability for superheat. Steel piping meets these requirements much better, the sole objection to it being possibility of quicker corrosion. The corrosion from the steam side is of no more importance than in land practice, however, and the exterior corrosion, as Professor Christie suggests, should be cared for by suitable painting. Properly covered pipe should be safe from external corrosion, provided the covering is kept unbroken (particularly around joints) and well painted. The covering presents a considerable resistance to the flow of salt water along the outside of the pipe, and if the pipe has a fairly high temperature there is little or no danger of any liquid ever reaching the pipe itself, as at the slow rate of absorption the liquid is evaporated before it can reach the metal.

Expansion. More reliable provision for expansion can be made in a material of high elastic limit like steel than in copper, as indicated by experience with corrugated copper expansion joints of multiple bellows type.

These joints have not been treated as *springs*. They are deformed by the movement beyond the elastic limit, and dependence is placed on the ductility of the material to withstand such heroic treatment. This statement can be readily proved by compressing a copper joint to its full rated capacity; it will not return to the original face-to-face dimensions.

The consequence of this has been that the weakest convolution takes most of the bending, resulting in a fracture. This condition has been partly avoided and the life of the joint increased by adding spacing rings inside and outside the corrugations, limiting the movement of any individual corrugation, and more or less equalizing the deformations. If this type of joint were made of steel and treated as a spring, with no deformation exceeding the elastic limit, no trouble should be experienced. The success of this joint has been successfully proven by an English company manufacturing corrugated-steel barrels, which has brought out a perfectly satisfactory steel joint without spaces. An Australian (Beiliez) company has also developed a process for making corrugated pipe either in straight lengths or bends, which has from 15 to 20 times the flexibility of uncorrugated bends. We therefore have available suitable means for taking care of expansion without resorting to packed expansion joints of the slip type.

Piping. The enormous and successful use in land practice of the lap or Van Stone joint, and also of the welded header-and-line joint casts a doubt upon the wisdom of excluding them from marine work.

No tests have been published showing any well-grounded reason why these devices cannot be successfully used for marine work. One of the particularly advantageous features of the lap joint for marine work is the loose flange and consequent ease of alignment of bolt holes.

The tendency in land practice is to increase the use of welded work, and the writer has expressed the opinion that for extreme pressures and temperatures welding should be universal.

Valves and Fittings. The writer believes in strict specifications for the material for high-pressure steam valves. Cast steel should be used for all high-pressure steam work; the use of semi-steel is unsafe, as the mixtures are unreliable. It would be better to encourage the development of a cheaper steel casting than this hybrid material of uncertain characteristics.

The writer's practice on high-pressure work is to use flanged joints on everything of 3 in. and over; on low-pressure work (except for drainage piping under very light pressure) flanged joints on 4 in. and over. No trouble has been experienced with the smaller screwed work.

The use of gate valves should by all means be encouraged; for all line purposes they are as tight as globe valves and of course much reduce friction loss. For throttles and stop valves the globe or angle type will necessarily be retained.

Flanges. The writer does not feel that the revival of six-hole flanges in the small sizes noted by Professor Christie is either necessary or desirable. The stresses involved for all sizes under the A. S. M. E. standards were figured from the same basis; consequently there is no excuse for a change on that ground. But the six-hole flange permits of only two positions of a standard drilled fitting, whereas the four-hole drilling permits of four. This is of very considerable value if field or special drilling is to be avoided.

Another desirable consideration in favor of the purchase of standard accessories such as reducing valves and relief valves, is that the makers of these devices are doing nothing else, and are selling the goods on their merits. The designs are therefore more likely to be satisfactory than where produced by marine designers to whom they are only an occasional undertaking.

The lavish use of brass and copper pipe could probably be much reduced without any decrease in reliability. For instance, brass pipe is now much less used for boiler-feed lines, except for the short section between the feed-regulating valve and the boiler drum.

Another cause which enormously restricted the output of the tube mills was the requirements for condenser tubes. The Government and consequently the shipyards maintained for over two years three inspection tests of such tubes that were incompatible, and in fact that forced the manufacturers to make a tube that was not desirable. The three tests were the hammer, pin and compression tests. The hammer test (crushing the tube flat to three times gage overall) and the pin test (expanding $16\frac{2}{3}$ per cent in diameter) would be satisfactory if a soft tube were furnished. But the compression test (loading with definite weights across the tube and limiting the permanent set) requires a hard tube which in view of the season certain to occur is very undesirable. The reason for its adoption was ostensibly to guard against crushing by packing too tightly with the corset lacing.

As a matter of fact, a hard tube can be crushed by abuse in packing as well as a soft tube, and further, corset lacing was abandoned years ago by up-to-date power-plant operators for fiber ferrules, which are a better material and with which it is difficult to crush any tube. The hard tube is certain to cause trouble if expanded into the tube sheets (as in the destroyers), yet it required two years' effort to get the compression-test limits raised from 0.005 to 0.020. With regard to both condenser tube and all other brass and copper tube the Society would confer a lasting benefit, increase tube capacity, and decrease cost, by standardizing the sizes and specifications.

R. J. S. Pigott.

Bridgeport, Conn.

We are advised by Dr. William Paul Gerhard that in the Annual Report of the Library Board, published in the February 1919 issue of Mechanical Engineering, p. 183, an error has been made in stating that the collection of books on gas engineering was presented by him to the American Gas Institute. Dr. Gerhard states that these books were originally donated by him to the Illuminating Engineering Society, and transferred to the Library by that society, with his approval.

ENGINEERING SURVEY

A Review of Progress and Attainment in Mechanical Engineering and Related Fields, as Gathered from Current Technical Periodicals and Other Sources

AERONAUTICS

The Aeroplane in Curvilinear Flight (*Schaerer. Aero. Club Bulletin*, Nos. 8 and 9). The article describes an investigation into the attitude taken up by an aeroplane in curvilinear flight. It is admittedly only a very approximate method, assumptions being made in order to simplify the mathematics. When an aeroplane turns, it banks, and if the banking is excessive the machine sideslips inward, the opposite being the case if the angle bank β is not large enough. First of all the author examines the relation between β and other quantities, defining the machine and the motion.

If ρ be the radius of curvature of the path and V the velocity, then the angle of bank β is given by $\tan \beta = V^2/\rho g$, assuming the sine law for the resistance of the planes.

A few remarks are made on the gyroscopic effect of the airscrew either in assisting or opposing the banking movement, together with a consideration of the difference in the lifts on the two wings due to the circular motion.

The effect of the angle of the rudder is next examined, and an expression is derived for the radius of curvature of the path. If F_s be the area of the rudder, and a the initial value $(t = 0)$ of the angle through which the rudder is turned, then the component forces acting on the rudder parallel and perpendicular to the longitudinal axis of the machine are respectively—

$$R_s = v^2 F_s \sin^2 a \, \psi \gamma / g$$
$$A_s = v^2 F_s \sin a \cos a \, \psi \gamma / g$$

γ = the density of the air and ψ is a constant coefficient. The latter force produces a moment about the vertical axis through the center of gravity and if the average be l, M can be written in the form

$$M = C \sin 2a$$

C being assumed constant and equal to $\psi \gamma l v^2 F_s / 2g$, and the moment produced by R_s neglected in comparison with M. Further neglecting the opposing moments due to difference of the relative speeds of the outer and inner wings, the equation

$$\frac{d^2 \phi}{dt^2} = \frac{C \sin 2a}{J}$$

is obtained, where ϕ is the angle between the original rectilinear flight path and the axis of the machine at time t, and J the moment of inertia about the vertical axis through the center of gravity.

On the integration this gives the angular velocity

$$w = \frac{C \sin 2a}{J} t$$

and the angular displacement $\phi = \dfrac{C \sin 2at^2}{2J}$ and since $\phi = vt/\rho$,

$$\rho = 2vJ / C \sin 2at$$

In actual flying the banking of the machine due to difference in the speed of inner and outer wings will cause the machine to "take the curve" and the centrifugal force will balance the lateral force so as to do away with sideslipping.

It is admitted that the above formula for ρ is only a rough approximation, assuming as it does the constancy of a and v. At large values of β, M is usually small; for the extreme case $\beta = 90$ deg., it vanishes. J also ceases to be a principal moment of inertia for values of β other than 0 deg. or 90 deg. Still it is claimed that the approximation is good for the values of β up to about 25 deg. Further,

$$\tan \beta = \frac{v^3 F_s l \sin 2a}{4gJ}$$

Finally a few calculated values of β are given for $a = 5$ deg. and 10 deg. and for values of t varying between $t = 1$ and 20 sec., and the personal element introduced into the control of the machine is discussed. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 1, Jan. 7, 1919, no. 3838, p. 22)

Douglas Automatic Aeroplane Ignition Interrupter. The Douglas interrupter was primarily developed for military planes but it may find application also in peaceful aeronautics.

In the event of the propeller's breaking there results a seriously unbalanced condition of the plane. In a tractor plane the tendency is to go into a dive and in a pusher plane to go into a tail stall, and either type of machine is apt to pass into a spin as a result of the unbroken propeller blade tending to swing the machine around a neutral point between the center of pressure of the unbroken blade and the center of torque.

In addition to this the unbalance of the power plant itself due to the unequal torque is apt to break a gasoline line and cause fire.

The operator cannot always be relied upon to cut off the power quickly enough, since the time interval per revolution for aeroplane engines at full throttle varies from 1/23 to 1/27 of a second and conditions may get beyond repair long before the aviator realizes what is wrong with the plane.

The interrupter acts automatically and through practically instantaneous action cuts off the power, thereby confining the danger to the initial breakage, which is seldom serious in itself, provided it is not followed by unbalanced power development. Such an interrupter is probably particularly valuable in the case of twin-engined planes, as such an accident happening to one engine would cause the good engine to suddenly swing the machine around and probably into a spin.

It may be added that, from this point of view, the interrupter practically plays the part of the self-locking differential as preventing the skid of an automobile on a slippery pavement, though acting in an entirely different manner mechanically.

The instrument is very simple and may be briefly described as consisting of a suitably pivoted metal bar so mounted as to swing in a plane transverse to the axis of rotation of the propeller.

Under normal operating conditions the free movement of this bar is confined to a very limited arc in its plane of movement by means of tension springs. The amplitude of this movement is determined by the weight of the bar, the intensity and frequency of the transverse vibrations of the engine and the opposing strength of the springs confining it. An intense oscillating shock trans-

verse to the engine such as an unbalanced engine propeller torque reaction resulting from the breaking of a propeller at speed or similar causes will force the bar to swing through its full amplitude, raise a trigger usually held by a compression spring and in this way interrupt the ignition through grounding the magnetos.

On the other hand, there is a compression spring—in itself presenting an unbalanced force—which is designed to prevent the bar from disengaging the ignition latch as a result of cylinder misses coinciding with bad vibration periods of the engine, lateral shocks to which the plane may be subjected at landing, etc. In this way the interrupter automatically differentiates between harmless vibrations and intense oscillating shocks transverse to the axis of the engine which may cause a dangerous state of dynamic unbalance.

It was feared at first that the presence of this instrument would be apt to complicate ignition, particularly so on the Liberty engine where the double distributor system is used. Actually, however, it has been found that no trouble results from its installation.

Two types of interrupters have been developed; one of the Mecca type for magneto ignition, and the other of the breaker type for battery-generator engines, such as the Liberty. (*Aerial Age Weekly*, vol. 8, no. 23, February 17, 1919, pp. 1121 and 1141, 4 figs., *d*)

Italian Aircraft Engine as Redesigned in U. S. A.

THE KING-BUGATTI AVIATION MOTOR, G. Douglas Wardrop, Mem.Am.Soc.M.E. An interesting feature of this motor is that it represents practically a foursome assembly. There are four carburetors, each supplying one block of four cylinders and likewise four magnetos, two on each side of the engine (Fig. 3).

The carburetors are specially designed Miller, feeding through separate water-jacketed manifolds. They are set low so that gravity feed may be used and all four are identical, there being no rights or lefts.

Fig. 1 shows the carburetor assembly, which apparently does not very materially differ from the ordinary Miller carburetor.

The throttle valve is of the barrel type; the axes of all valves being parallel with the center line of the engine, the two carburetors on each side of the engine being operated by one shaft which is connected with the valves at each end through adjustable couplings. The shafts on the two sides of the engine are connected so that all four valves move in unison, the valve openings being synchronized by means of adjustable couplings.

From the float chamber which is controlled in the usual manner the gasoline enters the jet holder in which there are seven jets with drill sizes from No. 76 for idling to Nos. 76, 75, 71, 68, 57 and 53. These jets progressively come into action as the throttle is opened, thus gradually giving an increasing supply of gasoline.

Gasoline is drawn into the jet through the small hole in the bottom of the threaded end, mixing with a certain amount of air sucked in through the four holes drilled in the barrel of the jet just above the threaded portion. This air is taken from the outside through the upper 3/16-in. hole in jet holder and passes down around the outside of the jet to the four holes mentioned above. The major portion of the air enters the carburetor through the lower end of the venturi, which is 3 in. in diameter, passes up around the jet bar holder, combining above this with the rich mixture from the jets to form the proper mixture for combustion.

Assembly of the altitude valve is shown on drawing (Fig. 2). This valve operates by turning the lever which is attached to the altitude-control valve. This valve has two openings in its seat which when in the open position register with two similar openings in the stationary cover, thus making two free passages to the outer air, the size of these passages being governed by the position of the lever.

There are four outlets (Fig. 2), one of which connects to each of the four elbows, opening directly into the top of the float chamber. The float chamber is always in direct connection with the venturi through a 5/64-in. drilled hole opening into the venturi about 1/4-in. above the jet holder and into the float chamber well above the gasoline level. Opening the altitude-control valve decreases the vacuum thus increasing the flow of gasoline through the jets.

Oiling is by pressure feed and spray. There is one pressure and one scavenging pump, both of the rotary-gear type. These are located at the front of the engine, driven directly from the crankshaft through a pin and slotted coupling, Figs. 4 and 5. This coupling is squared to the pump shaft but is not pinned, thus relieving the shaft of any end driving pressure. The gears in both pumps are the same except that the scavenging pump gears have a wider face. The oil is forced into the pressure line running the entire length of the crankcase. An adjustable pressure-regulating valve is located in the crankcase front-gear cover, generally set so that the pressure gage which is connected to the rear end of the main oil line in the crankcase registers about 30 lb.

This valve has holes drilled through the head so that there is always a certain amount of oil discharged on to the gears.

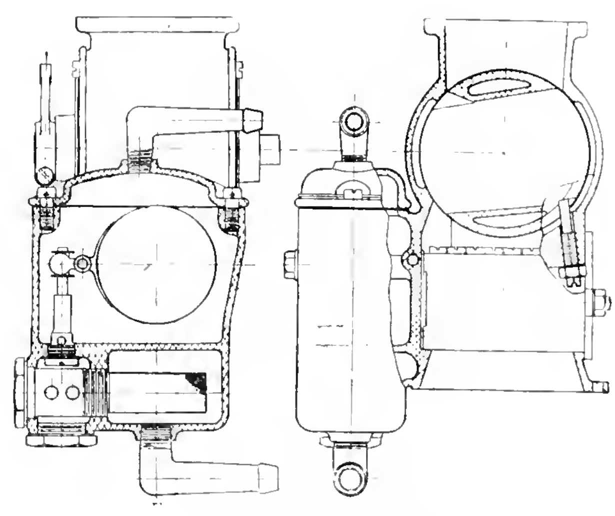

FIG. 1 CARBURETOR ASSEMBLY

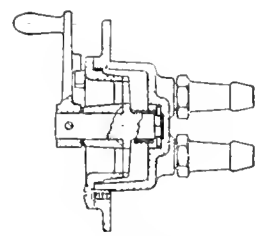

FIG. 2 ALTITUDE-CONTROL-VALVE ASSEMBLY

Cooling water is circulated through the engine by means of a centrifugal pump, see Fig. 6, driven from the rear end of the left-hand crankshaft by a pin and coupling the same as used on the oil pump.

The cooling system from the pump inlet to the outlet elbows on the front cylinders holds $4\frac{1}{4}$ gal. of water.

The pump impeller is $5\frac{1}{8}$ in. in diameter with eight vanes, the web being drilled with eight 3/8-in. holes on a circle of 2 in. diameter to equalize the water pressure.

The pump shaft is packed with a graphite-asbestos rope packing, automatically held together under compression by a coiled spring acting on the gland.

The pump shaft is hollow, the rear end being in direct communication with the water in the pump case. Water entering the shaft is pumped out to the shaft rear-bearing surface through a 1/8-in. hole. Any leakage of water past the asbestos packing is drained outside of the crankcase through a 5/8-in. cored hole in the water-pump body. The front bearing on the pump shaft is lubricating by spray from the crankcase which collects on the shaft-bushing support and drains down into a 1/8-in. hole leading

to the bearing. Any oil leakage from the front end of this bearing returns to the pump, and slight leakage from the rear end of the bearing is drained outside of the crankcase with the water leakage from the rear bearing.

There is one water inlet to the pump $2\frac{1}{4}$ in. in inside diameter while the single outlet is $2\frac{3}{16}$ in. in diameter. Water from the pump is forced up into an aluminum pipe with one branch leading to the rear end of each of the rear cylinder blocks, water entering the cylinders at the top of the water jacket on the exhaust side. A certain amount of the water circulates through the inlet manifold jacket, the remaining filling the cylinder water-jacket space.

Cylinder blocks are cast with integral water jackets, except the sides below the inlet and exhaust ports, which are covered by an aluminum water-jacket plate held in position by screws.

The construction of the water passages in the head of the cylinder is such that the valve stems and exhaust passages are very thoroughly cooled.

All four cylinder blocks are identical, the water passing from the rear to the front cylinder blocks through openings similar to the inlet opening, leaving the front blocks through another similar opening.

The crankshaft is made in two pieces connected at the center by a taper and key drawn up with a nut. Each section of the shaft forms a four-cylinder shaft with the throws all in one plane, the throws of the two sections being assembled at right angles. In assembling the rear end of the front half is immersed in boiling water the tapering end of the rear section which is cold is then slipped into position and the parts drawn together by the nut, using a long-handled wrench. The rear end of each complete shaft has clutch teeth cut on it for attaching the starter. All bearings including the connecting-rod bearings, with the exception of the center main bearings, are undercut. This results in a total shortening of the shaft of approximately 4 31/32 in. This results in a considerable saving in the weight of various parts, while still allowing ample bearing surface. The crankshaft main bearings are bronze bushings babbitt-lined. They are not relieved at the parting line and in the majority of them there are no oil grooves at all.

Contrary to the system used in the Liberty engine, the cylinders are of iron cast in blocks of four. The water jacket is cast integral, with the exception of the sides of the cylinder block below the inlet and exhaust ports, which are covered with the cast aluminum plate attached with screws. The cylinders are bolted directly to the top of the crankcase without the use of a gasket, but a gasket is used between the water-jacket aluminum plates and the cylinder. Provision is made for a liberal circulation of water in the neighborhood of the valve ports, seats and guides. The spark plugs, of which there are two per cylinder, are located at the side of the combustion chamber in close proximity to the

inlet valves and are well cooled by the circulating water. (*Aerial Age Weekly*, vol. 8, no. 22 and 23, Feb. 10 and 17, 1919, 51 figs., *d.t*)

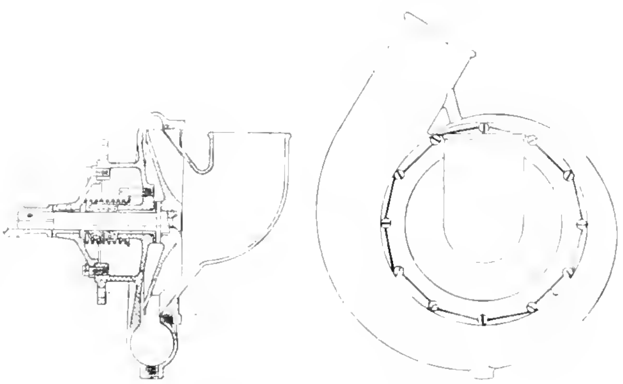

FIG. 6 WATER-PUMP ASSEMBLY

CEMENT AND CONCRETE

INFLUENCE OF VIBRATION UPON CONCRETE (*Deutsche Bauzeitung*, Sept. 28, 1918). In concrete construction it is generally believed that vibration during the period of setting has a bad effect, so that it must be prevented as much as possible. On the other hand, tests made by von Bach in 1905 on the frictional resistance of iron reinforcement in concrete showed that this was increased by vibration during setting and varied inversely with the quantity of water present in the concrete mass.

The German Committee for Reinforced Concrete decided to make further tests to verify von Bach's results, and the figures are set forth in a pamphlet of 88 pages, with 33 tables and numerous photographs of fractured test beams. The vibration or shaking is divided into three classes, which are described in detail. The test beams of a transverse section 20 cm. by 30 cm. were laid across supports 2 m. apart. They were made of concrete composed of 1 part cement to 4 parts of gravelly sand, or 1 part cement, 2 of sand, and 2 of syenite broken fine and reinforced with iron rods of 16 mm. section. Both kinds of concrete were used in three degrees of dampness. Fluid concrete is more sensitive to vibration than concrete with less water. The precise figures for surface friction in the iron are not given. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 2, no. 13, Dec. 24, 1918, no. 3619, p. 364)

GAS PRODUCERS (See Mechanical Processes)

HYDRAULIC MACHINERY

A New Type of Water-Turbine Governor

WATER TURBINE AT THE HYDROELECTRIC PLANT AT KUBEL, SWITZERLAND. Description of a new turbine and governor installed at a Swiss hydroelectric plant by the Escher-Wyss Company.

This turbine was installed in 1915 and is rated at 2500 hp. at a speed of 500 r.p.m. The turbine presents several interesting innovations both on the hydraulic and the electric end. Thus, the alternator bed has to support only the weight of the shaft end and the rotor, but does not have to take care of any load coming from the turbine itself, as the axial thrust is hydraulically balanced by means of a special device. This balancing is produced by the pressure of the water circulating in two annular passages located on each side of the runner. To make this possible, the runner has its two faces carefully ground and so arranged that there is an interval of a few tenths of a millimeter between the runner faces and the corresponding surfaces of the side bracket on one side, and the discharge pipe on the other side. If the runner should shift from its central position the pressure, because of the change in volume of the interval, will rise in one of these annular passages, while it will fall off in the other, and this will tend to bring the runner back into its central position.

The most interesting feature in the installation is the new type of Escher-Wyss governor. Its general construction is shown diagrammatically in Fig. 8, and its essential characteristic lies in the fact that the interruption in the governing movement is as a rule produced just at about the same time when it is necessary.

The double servomotor (2-3) is located in the casing (1), which also serves as an oil reservoir. The movements of the double piston are transmitted by a special articulated lever (4) to the governor shaft (5), which, in its turn, operates the governing organs of the turbine. The distribution of pressure on both sides of the servomotor is effected by means of the valve (7-7*a*) also located in the casing, while the gear pump thus forces by the passage (30) oil under pressure to the centrally located chamber (31) of the governor valve. The same chamber (31) has connected to it the safety valve (8) loaded by means of a spring which regulates the maximum pressure of the oil in the governor. The chambers (32 and 32*a*) respectively located above and below the governor valve provide a means of escape to the oil and are directly connected to the reservoir (1), while the central chambers (33 and 34) are connected by passages (33*a* and 34*a*) to the respective cylinders (3 and 2) of the servomotor, in addition to which these two sides of the servomotor can be placed into communication by means of a valve (9). The edges of the governor valve as well as the distribution valve (7 and 7*a*) have only a very small amount of play when the governing mechanism is in its neutral position and the pump works then at only very low pressure, but this pressure automatically rises when governing becomes necessary so as to overcome the resistance of the servomotor.

The stem of the distribution valve has two collars (12*a*) the purpose of which is to limit its movements, and the distribution valve itself acts through two double levers (11 and 11*a*) between which is located the dashpot (18). This action does not occur directly by means of the centrifugal pendulum (13), but is effected through a device called pre-command, the construction of which has been described on other occasions. This pre-command device is embodied into the upper part of the centrifugal pendulum and, among other things, comprises a differential piston (35). The spring pendulum operates solely the spindle (14), which, turning with the pendulum, makes an integral part therein and influences the distribution of pressure in the differential piston.

A special arrangement is described for very large governors. The operation of the governor during the process of speed regulation is as follows: As soon as the speed of the turbine and that of the spring pendulum (13) rises above the normal value the spindle (14) is raised and the opening in the diaphragm (37) closes so that the whole pressure is applied under the piston (35).

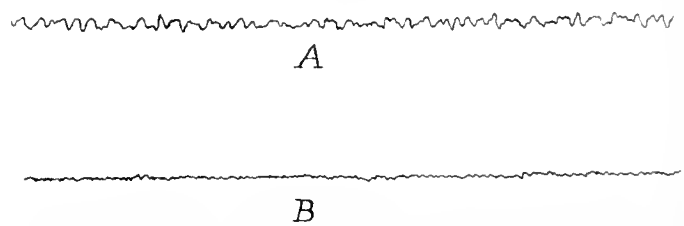

FIG. 7 TACHOGRAMS WITH THE OLDER TYPE OF ESCHER-WYSS GOVERNOR (A) AND THE NEW GOVERNOR (B) OF THE SAME COMPANY

This piston follows the movement of spindle (14) and raises the operating lever (11), which then instantaneously turns around point (19).

The casing of dashpot (18) is then carried away by the larger spring inside of it and the operating piston (7) is also raised by the casing (18). Since the entire travel of the piston is very slight, a short movement of the spindle (14), that is, a very small change in the number of revolutions, is sufficient to displace over its entire path the piston of the distributing valve and thus communicate the greatest possible speed to the servomotor.

When the piston (7) is in its upper position, this on one hand produces communication between cylinder (2) of the servomotor and the oil pump, and on the other hand opens the connection between cylinder (3) and the outlet passages, which results in a

movement from left to right and produces the closing of the double piston of the servomotor. During this process of governing the number of revolutions of the turbine per unit of time will rise until the servomotor has attained a position corresponding to the new load. During this time the piston (7) preserves its highest position and the cylinder of the dashpot cannot, of course, move any further. Nevertheless, under the influence of the continuing increase in speed the spindle (14) continues to rise together with the pre-command piston (35) and lever (11). As a result the piston enclosed in the dashpot (18) is displaced upward and compresses the upper spring still more. But as soon as the speed of the spring pendulum decreases to such an extent that the spindle (14) and hence the pre-command piston (35) begin to fall down, the cylinder dashpot (18) instantly joins its piston because of the oil contained therein. This new position is shown in Fig. 8 at the top and to the right. Because of this the piston of the distributor valve (7) is instantly brought to its middle position and the movement of closing is interrupted, which always happens immediately after the peak of the speed curve is exceeded or at the moment when the position of the servomotor corresponds to the new load. Then, under the influence of the larger spring on the dashpot, the easing of this latter is gradually brought to its middle position and the proper velocity corresponding to the new load is established.

On the other hand, if the speed of the turbine falls below its normal value because of the overload, the same operations take place in an inverse order. In both cases the auxiliary mechanism (16) operates in the usual manner and may be adjusted for either positive or negative effect and for isochronous regulation. The most usual system in the case of turbines driving three-phase generators is to give the auxiliary mechanism a slightly positive action corresponding to only a part of the pendulum motion, while the other part of this motion is likewise used but for varying the speed.

In order to increase the sensitiveness of the apparatus, the pendulum used runs at a very high speed and its inertia masses are reduced to the strictest minimum. Further, the hydraulic pilot piston (35) is located in the immediate vicinity of the pendulum which leads to complete suppression of disturbing oscillations. It is claimed as a further advantage of the new governor that all of its rotating parts are located inside of a casing which prevents projection of oil outside; also, the oil reservoir is completely enclosed and is thereby protected from access of impurities.

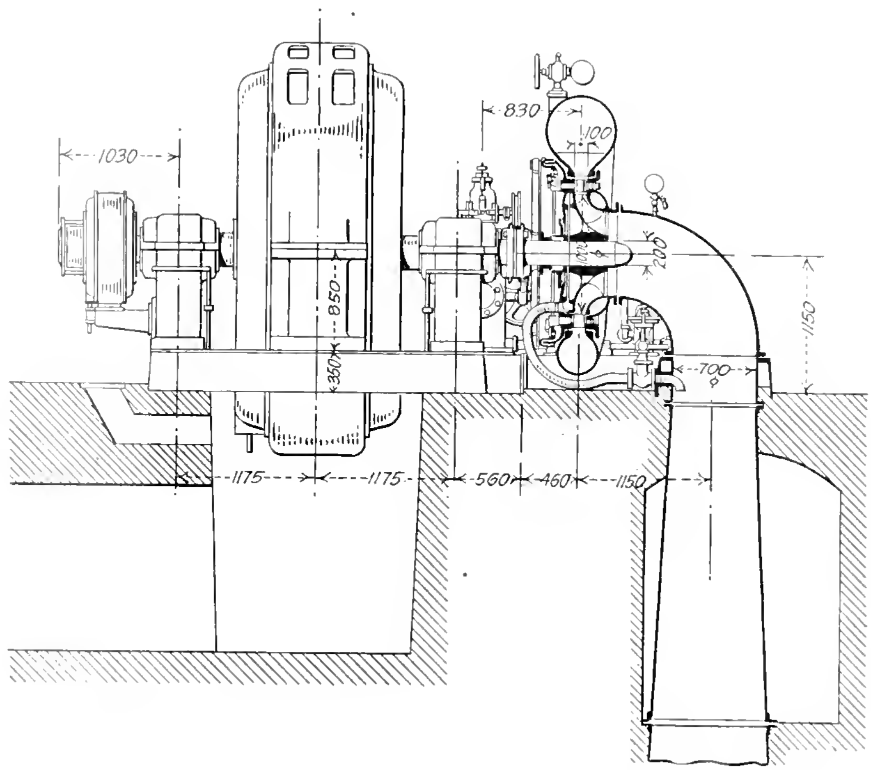

Fig 9 Axial Section of the Swiss Hydraulic Turbine at Kubel

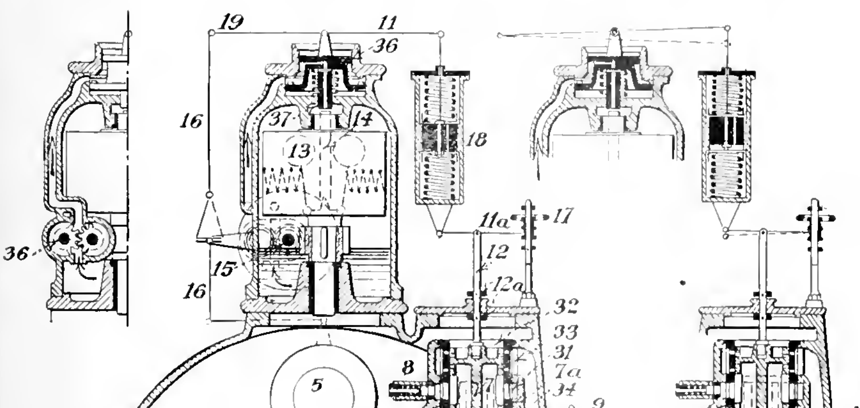

Fig 8 Section and Details of the New Governor on the Kubel Hydraulic Turbine

Acceptance tests were carried out in October 1916 and are claimed to have given excellent results. Of particular interest are tachograms taken; the first (A) on six turbines equipped with the old-style governors, and the second (B) on six other machines equipped with the new governor. A glance at the two curves indicates the great improvement made by the use of the new apparatus (Fig. 7). (La nouvelle turbine de 2500 ch de l'usine hydro-electrique de Kubel près Saint-Gall (Suisse), P. V. *Revue Générale de l'Electricité*, vol. 5, no. 1, Jan. 4, 1919, pp. 19-25, 9 figs., *dA*)

INTERNAL-COMBUSTION ENGINEERING (See also Aeronautics)

The High-Compression Oil Engine, W. G. Gernandt. Comparative discussion of high-compression oil engines of various cycles, covering the four-stroke constant-volume or Otto engine, the Diesel or high-compression engine, the Hvid engine, the McClintock and the Gernandt engines. The writer gives in each case a brief summary of what he considers the advantages and disadvantages of each cycle.

In the Gernandt engine the fuel is injected into the combustion chamber by supercompressing a portion of the products of combustion which have been trapped at the time the pressure in the cylinder has attained its maximum. Mechanically this can be accomplished in various ways, depending on the general design of the engine, and the trapping chamber may be actually sealed by the use of valves between the supercompressing means and the combustion chamber, or be in direct communication with the combustion chamber through very small injector holes.

The injection itself takes place as follows: Taking the case of a four-cycle engine the fuel is deposited during the suction stroke in a small chamber between the combustion chamber and the supercompressing means. This fuel is metered and passed through a mechanically timed valve. During the compression stroke the fuel attains the necessary temperature and the pressure rises in the fuel chamber. When the piston reaches its upper dead center the products of combustion previously trapped are supercompressed mechanically and forced through the fuel chamber and into the combustion chamber. (This sentence is repeated verbatim from the original article. From it, it would appear that combustion takes place previous to supercompression.)

It is claimed that, contrary to what occurs in the Diesel engine, the injection gas is highly heated and refrigeration has been practically eliminated, the amount of fuel necessary for injection being so small that the burning effect has not been impaired. Also there is no burning of the fuel until it is actually injected into the combustion chamber.

It is claimed that actual tests on this method of injection have shown promising results. No data of tests are, however, reported in the original article, except in answer to some questions during discussions. From these it appears that the engine which gave promising results is a 4-in. by 6-in. single-cylinder stationary engine in which the speed ranges from 200 to 860 r.p.m. No data as to horsepower developed are given. The compression is about 450 to 500 lb., depending upon the fuel used. The control of the engine is entirely by the amount of fuel burned. The needle valve regulates the quantity of fuel. Runs have been made at speeds as low as 200 r.p.m.

No data are given as to the amount of power developed at the various speeds. (*Journal of the Society of Automotive Engineers*, vol. 4, no. 2, February 1919, pp. 112-118. 3 figs., *cd*)

MACHINE DESIGN

INVENTION IN SMALL MECHANISM (*Technique Moderne*, October 1918). The small mechanism to which the present article alludes is that of a size most commonly used in watchmaking, etc.

It is not sufficient to have a knowledge of kinematics and forms of mechanisms to be able to design machines. It is necessary, first, to be familiar with the characteristics of small mechanism, then to know how to state a practical problem for solution, so as to be able to unite the experimental data which are concerned and to think out tests on apparatus which are the embryos of the machines to be built.

The choice and the design of cams play the principal share in this second part of the realization of an industrial invention: they are governed by simple rules that are ignored by too many inventors, whereas if these rules are followed the efficiency of the machine can often be increased.

The author treats the subject in considerable detail over eight pages of the journal. The first portion deals with the general problem; this is followed by a section dealing with the classification of types of cams and study of motions caused by cams and rollers. Section 3 discusses the stages of a mechanical invention, and, finally, the author illustrates his idea by describing a complicated machine for making the paper tubes for cigarettes. The object is to show that there are rules and methods of procedure which should be followed in the process of mechanical invention, and that if they are carefully followed far better results will be attained than if mere rule-of-thumb methods and random experiments are made. The author, Mr. Emile Belot, has successfully designed a large number of machines for industrial purposes. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 1, Jan. 7, 1919, no. 3750, p. 8)

MACHINE SHOP

BOILING TANKS IN LOCOMOTIVE WORKSHOPS (*Organ für die Fortschritte des Eisenbahnwesens*, Oct. 1, 1918). In the locomotive repair shops at Karlsruhe steam-heated boiling tanks have been installed, in which the parts of locomotives and vehicles are cleaned before they are repaired. The tanks are large enough to receive the bogie frames, and the installation comprises the boiling tank containing the washing fluid; the rinsing tank, in which the boiled articles are treated with cold water; a tank in which the washing fluid is cleaned for use again; and an overhead crane. In one installation the washing fluid is heated by the admission of steam through nozzles, and in the other it is heated by steam coils. The advantages and disadvantages of the two systems are discussed in the article. The working drawings to scale are reproduced in plates, which are bound up with the journal.

The washing fluid consists of 100 grams of 80 per cent caustic soda to 1 liter of water, the whole kept at a temperature of 80 deg. to 90 deg. cent. The use of steam boiling nozzles is not recommended, as the solution is gradually weakened; heating by steam pipes is much better, but the water must be kept stirred. The fluid is pumped out of the boiling tank and lifted to the storage tank at high level by a centrifugal pump, the suction pipes inside the boiling tank having nozzles pointing upward. The stirring of the boiling liquid is now effected by means of a jet of air under pressure. Complete bogie frames can be thoroughly cleaned in 50 to 70 min., and the air jet is only required for the last 15 min. The cost of steam is the most important factor. The boiling tank is 7 m. long by 3.213 m. wide by 1.500 m. deep, and the author gives calculations for the consumption required. Most of the dirt falls to the bottom of the boiling tank, and the proposed filtering apparatus in the high-level tank is not yet perfected. With the large new apparatus it is found that a saving in cost of cleaning of 40 per cent is effected, as against the former system, in which small tanks and steam nozzles were employed, and the cleansing is far more thoroughly done. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 2, Jan. 21, 1919, no. 3839, p. 39)

THE EFFECT OF TEMPERING ON WATER-QUENCHED GAGES. The following information has been supplied by Automatic and Electric Furnaces, Ltd., 6, Old Queenstreet, London, S. W.:

Two gages of $\frac{3}{4}$ in. diameter, 12 threads per inch, were heated in a Wild-Barfield furnace, using the pyroscopic detector, and were quenched in cold water. They were subsequently tempered in a salt bath at various increasing temperatures, the effective diameter of each thread and the scleroscope hardness being measured at each stage. The figures are in 10,000ths of an inch, and indicate the change + or — with reference to the original effective diameter of the gages. The results for the two gages have been averaged (Table 1).

TABLE 1

Thread	After quenching	Tempering Temperature, Deg. Cent.					
		220	260	300	340	380	420
1	+25	+19	+17	+15	+13	+11	+11
2	+18	+12	+11	+ 9	+ 6	+ 5	+ 5
3	+12	+ 6	+ 5	+ 3	0	0	0
4	+10	+ 4	+ 4	+ 2	. .	0	— 1
5	+ 9	+ 4	+ 1	+ 2	0	0	0
6	+ 9	+ 4	+ 3	+ 2	0	0	0
7	+10	+ 5	+ 5	+ 3	+ 2	+ 1	+ 2
8	+ 8	+ 4	+ 3	+ 2	0	0	+ 1
9	+ 9	+ 4	+ 3	+ 2	+ 1	+ 1	+ 1
10	+ 9	+ 5	+ 5	+ 3	+ 2	+ 2	+ 2
11	+ 7	+ 4	+ 4	+ 2	+ 1	+ 1	+ 1
12	+ 9	+ 5	+ 5	+ 5	+ 4	+ 4	+ 3
Scleroscope	80	70	70	62	56	53	52

Had these gages been formed with a plain cylindrical end projecting in front of the screw, the first two threads would have been

prevented from increasing more than the rest. The gages would then have been fairly easily corrected by lapping after tempering at 220 deg. cent. Practically no lapping would be required if they were tempered at 340 deg. cent. There seems to be no advantage in going to a higher temperature than this. The same degree of hardness could have been obtained with considerably less distortion by quenching directly in fused salt. It is interesting to note that when the swelling after water quenching does not exceed 0.0012 in., practically the whole of it may be recovered by tempering at a sufficiently high temperature, but when the swelling exceeds this amount the steel assumes a permanently strained condition, and at the most only 0.0014 in. can be recovered by tempering. (*The Engineer*, vol. 126, no. 3286, December 20, 1918, p. 537, *ep*)

MACHINE TOOLS

Precision Lathe for Cutting Screw-Thread Gages

A British Precision Screw-Cutting Lathe. Description of a machine tool made by Alfred Herbert, Ltd., of Coventry, England, designed for the single purpose of cutting the thread on a screw gage. It is capable of cutting a screw up to 3 in. long on a cylinder up to 6 in. long and up to $2\frac{1}{2}$ in. in diameter.

Although the machine is intended solely for cutting screw threads, it is a true lathe and not a screw machine. The work revolves on centers and the cutter is a single-point tool clamped to a slide rest. The cutting movement on the tool is controlled by a lead screw and both the turning and the traveling movements are positively related by toothed gearing controlled by a single belt drive.

The main difficulties in cutting accurate screw threads on an ordinary lathe arise from—(1) Imperfect alignment between the axis of the work and the line of travel of the tool, a condition which may be due to distortion of the bed, warn centers, looseness of the spindle, etc.; (2) irregular or unsteady travel of the saddle; (3) want of means for making small corrections in pitch; (4) errors in adjusting the tool in the slide rest to the correct height and angle, and (5) the faulty clearing of the tool at the end of the cut and advancing it with the precise addition for the new cut.

These and other difficulties can all be overcome on an engine lathe by an experienced man of careful method, provided he be allowed a large proportion of non-cutting time. But even with the best of the engine lathes and the best of men screw cutting demands very close and sustained attention. The new lathe has been designed to facilitate thread cutting on screw gages and similar high-precision work.

A general view of the lathe is given in Fig. 10. The stands of the bed are inverted cast-iron boxes with walls of uniform thickness. The arrangement of the feet is shown in section at *A* in Fig. 12. The foot is a bolt with a ball-head extension which rests in a cup within a socket. One foot is secured against horizontal movement by making the cup a close fit in the socket, while the others have a little play to accommodate the movement caused by the expansion of the bed under a change of temperature. All three feet are held down to the stand securely but not harshly. The makers hold that distortion of lathe beds is mainly due to tying the bed down at four or more points and so producing on one hand a permanent stress by reason of inequality of pressure at these points and varying stresses by reason of the lack of freedom for expansion.

In the headstock both centers are stationary or dead. The work piece is fixed in with a carrier and is driven by a box pin. It should be borne in mind that only the screw cutting is done on this lathe, the piece being previously finished to thread-crest diameter. The driving plate *A*, Fig. 11, revolves on a bearing surrounding the fixed headstock center, and has spur teeth cut on its rim. The driving spindle is driven by a three-step pulley, and has a pinion *B* at one end gearing with the driving plate and a pinion *C* at the other end gearing with the change wheels. When a gear train is set the plates carrying it are rigidly bolted to the frame, so that the wheels work steadily together. The wheels *A* and *B*, Fig. 11, reduce the driving-plate speed to one-fourth of the belt-pulley speed; therefore the pinion *C* makes four revolutions to one revolution of the work piece. The lead screw is cut with eight threads to the inch.

The lead screw is short (it does not reach to the back of the driving belt) and lies well above the lathe bed and between the V-guides of the saddle. This position gives a more direct pull than does the usual under saddle frontal arrangement.

The lead-screw nut is carried on a bracket rising from an extension of the saddle. It is not a split nut, the arrangement

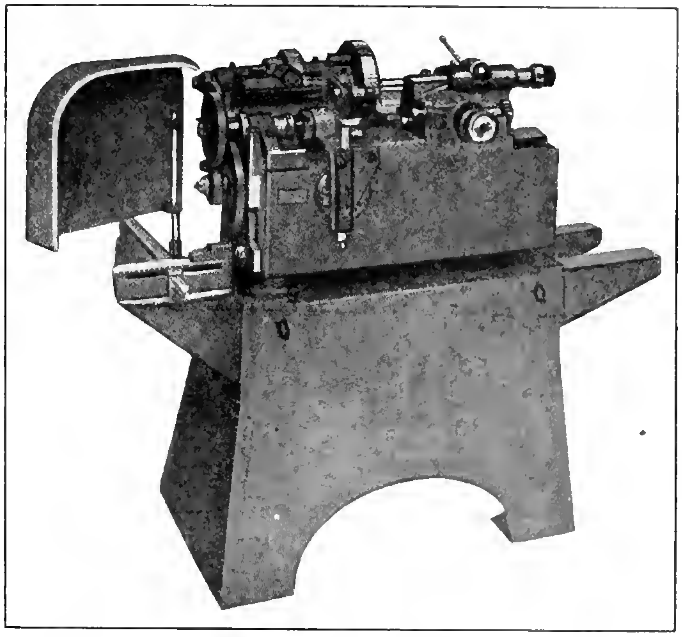

Fig. 10 General View of Precision Screw-Cutting Lathe

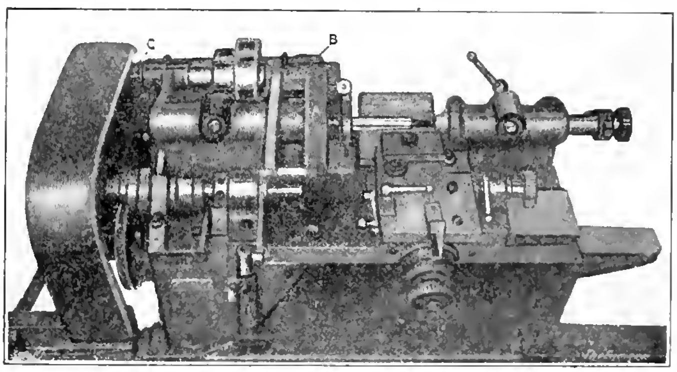

Fig. 11 Plan View of Precision Screw-Cutting Lathe

being that the reverse motion is obtained from the countershaft which is fitted with a two-speed reversing gear.

If the thread is cut correctly to pitch in the soft steel the pitch will be short when the steel is hardened. It is therefore necessary that a screw of, say, sixteen threads to 1.000 in. should be cut as sixteen threads to, say, 1.001 in., but this margin will vary with different steels and perhaps with different diameters. An extremely delicate means of varying the pitch is therefore necessary, and it must act evenly on every thread. This variation is obtained by the gear shown at the front of the lathe in Fig. 13. The vertical sliding rod carries a peg passing through its lower end and projecting into the slot plate attached to the bed of the lathe. The upper end of the sliding rod is attached to a lever arm controlling the lead-screw nut. The casing in which the rod slides is rigidly attached to the saddle and moves with the saddle in its travel. If the slot is set parallel with the lead screw the nut will be held stationary and the pitch of the thread will be cut true to the change-wheel setting. If the slot is set at an angle to the lead screw the sliding rod will move vertically and partially rotate the nut. The slot plate is graduated round its edge so that it may be

easily set to produce a variation of pitch either above or below the change-wheel setting. The graduations indicate 0.0001 per inch of screw to be cut.

The tool as shown at B in Fig. 12 is of special construction. The stock or shank is round in cross-section and is ground parallel to $^3/_4$ in. diameter, less half a thousandth. The total length is about $3^3/_4$ in. The grinding and lapping end to any angle, and to the necessary degree of accuracy, is provided for in a way which it is claimed puts this usually difficult operation within the reach

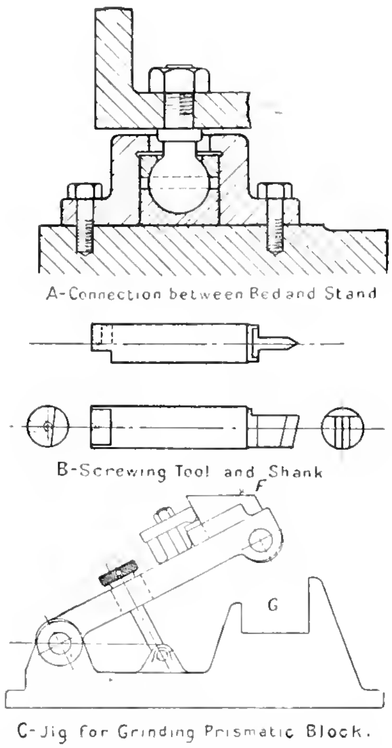

Fig. 12 Details of Precision Lathe

of an unskilled operator on a surface grinding machine. A block for holding the tool by its shank is provided in a jig on a box-like base which may be secured to a grinding-machine table. The holding block rests at an angle on a prismatic block which sets the surface to be dressed parallel with the grinding table. Everything, it is stated, is easily adjusted and secured so that by passing the tool under the grinding wheel the correct angle is obtained. The grinding of the prismatic block is provided for by a jig, as shown at C, Fig. 12, in which a sine bar is embodied so that the surface of the block to be ground may be easily and rapidly set to give the correct angle. The calculations of the precise angles of the prismatic block reduce to finding the thickness of a packing piece to be laid under the free end of the sine bar. The various thicknesses have been tabulated for all required tool angles. In Fig. 12 (C) the surface of the prismatic block to be ground is indicated at F and the space for the packing piece at G.

Where gages are being produced in quantity the roughing and finishing cuts for the thread may be taken on successive settings of the lathe or in two or more lathes operating in series. It is claimed that on this lathe unskilled operators are enabled to produce screw threads of the greatest precision that can be measured. One horsepower is required to drive the lathe and the total weight of the machine is a little over 14 hundredweight. (*The Engineer*, vol. 126, no. 3287, December 27, 1918, pp. 558-560, 9 figs., *d*A)

MEASURING INSTRUMENTS

Centrifugal Tachometers, Conical-Pendulum Type

Centrifugal Tachometers on the Principle of the Conical Pendulum (*Zeitschrift d. s Vereines deutscher Ingenieure*, Nov. 16 and 23, 1918). The article is in two parts and describes five main types of centrifugal tachometers. The general theory of each type is given, and the relation between n, the revolutions per minute, and α, the angular displacement of the arms of the conical pendulum, is worked out. There is for each type a variable β, such that $n = f(\alpha, \beta)$, and a series of characteristic curves of n against α are drawn for a range of values of β.

a Conical pendulum with flat-spiral-spring control. In this instrument the shaft, whose revolutions are to be measured, carries two arms in the form of a cross, each of which can turn about its center, i.e., about an axis at right angles to that of the shaft. Each arm also carries a ball at each end. The couple due to the centrifugal forces on the balls is balanced by that due to the pull in a flat spiral spring whose plane is parallel to the two arms.

The variable parameter β in this case is the angle α_0, which is the value of α when n is zero. The characteristic curves show that positive values of α_0 up to about 30 deg. give the best range of measurable speeds, and the most open space. α_0 is positive when the zero position (spring unstretched) is such that the spring is extended when the arms begin to move outward and away from the axis.

The angular movement of the arms is communicated by means of a pair of links to a sleeve which slides on the revolving shaft. The axial displacements of the sleeve are transmitted by means of a connecting rod and crank to the scale pointer. An excellent

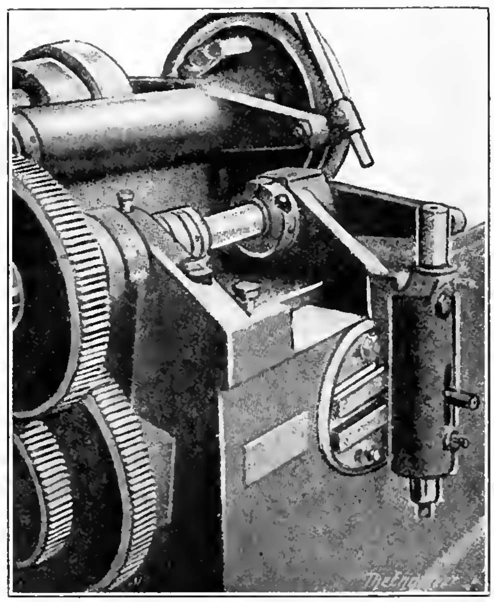

Fig. 13 Lead Screw and Nut of Precision Lathe

uniform scale over a fairly wide range of speeds can be secured in this manner; the best results are obtained if the joint of connecting rod and crank lies above the crank center when the shaft is at rest, assuming the axis of the shaft to be vertical.

b Conical pendulum with gravity load. This is an instrument on the principle of the Watt governor. It can only be used for limited ranges of speed. Characteristic curves are shown in which the variable parameter is the ratio between the distance of the hinges of the arms carrying the balls from the axis of rotation and the length of the arms.

c Conical pendulum with linear-spiral-spring control. This scheme is the basis of successful types of accurate tachograph. The pendulum masses are joined directly by the spring, and their arms are hinged about the ends of a bar which is at right angles to, and turns with, the shaft whose revolutions are to be measured. The angular movements of the pendulum arms are communicated by a link mechanism to a sleeve on the shaft, and the sleeve's movements are directly transmitted to the pen which traces a record on a revolving drum.

The characteristic curves are drawn with the unstretched length of the spring as the variable parameter. They show that the

principle is only applicable to cases where the speeds to be recorded are merely comparatively small variations from a constant mean.

d Centrifugal tachometers with differential gear drive. In these instruments the principle of the foregoing centrifugal tachometers, viz., a conical or rotating pendulum controlled by means of springs, is utilized, but the method of registering the deflection of the arms is essentially different. In outline the method is as follows: The displacement of the rotating pendulum masses produces a relative motion between two concentric shafts, one of which is connected to one side of the differential gear, and the other (a hollow shaft) is driven directly through bevel gearing from the main shaft. This hollow shaft has a speed of rotation equal and opposite to that of a second hollow shaft, also driven from the main shaft by bevel gearing, and connected to the other side of the differential gear. The above-mentioned relative displacement of the concentric shafts can therefore be seen as a displacement of the axis of the two middle wheels of the differential gear with respect to the axis of the shaft, and this latter displacement is registered by the indicator. The arms carrying the rotating pendulum masses have their hinges at opposite ends of the diameter of a rotating disk mounted on the hollow shaft, and the axes of the hinges are also those of a pair of toothed wheels which gear with a pinion on the inner shaft. Any displacement of the arms gives rise to a turning of the toothed wheels, and therefore to a relative movement between the two concentric shafts.

If the centrifugal forces on the rotating masses are balanced by flat spiral springs, then the characteristic curves are similar in character to those of type *a*. There are no improvements in the characteristics as compared with type *b* when the two means of the present kind of tachometer are joined by a linear spiral spring. An instrument can, however, be devised which gives an excellent linear relation between n and α and over a very wide range of speeds. The essential point of such an instrument is to choose suitably the position of the fixed end of a straight spiral spring which is attached at its other end to one ball only. The axis of the spring should be roughly at right angles to the mean position of the arm carrying the ball.

e Centrifugal tachometers with combined spring and gravity loading. The example given of this type is a combination of types *b* and *c*, and its characteristic curves are certainly an improvement upon those of either *b* or *c*, both as regards range and approximate proportionality between n and α. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 2, Jan. 21, 1919, no. 4015, p. 58)

MECHANICAL PROCESSES

Making Seamless Tubes. Description of the process of manufacture used at the plant of the Standard Seamless Tube Company at Economy, Pa., particularly interesting because of the fact that the plant has only been recently erected and therefore embodies the latest ideas in equipment and methods of manufacture.

The plant is equipped to make boiler tubes for stationary and marine boilers and for locomotives from 1 to 4 in. outside diameter, both hot-rolled and cold-drawn as well as seamless steel tubing for various mechanical processes.

Both basic open-hearth furnace and electric (Héroult) steel are used. Considerable care is used to remove all surface defects from the blooms, air-operated chipping hammers being provided for this purpose, the work going on day and night, with electric illumination during the latter period. Each workman engaged in chipping is required to wear goggles so as to protect his eyes against possible injury.

From the chipping house the bloom goes into a continuous heating furnace and from there it is delivered by a charging machine to a 23-in. bar mill. This mill consists of eight stands of three-high rolls arranged in parallel and driven by a motor through reduction gears. Two electrically driven tilting tables are placed on the front and rear sides of the roll stands. From the bar-mill rolls the bar is transferred by a runout table to the hot saw, which cuts the bar either into merchant sizes or to the size which the piercing mill is working.

This latter is of the Stiefel type and is electrically driven. In the mill the bar is passed through it over a mandrel, as shown in Fig. 14. After a hole has been pierced through the center of the bar the resultant tube is passed successively through a set of 22-in. electrically driven rolls and over a mandrel until the proper diameter and thickness are obtained.

The tube is then transferred to an expanding mill and thence through reeling mills from which it goes to a sizing mill where it is brought to final size according to specifications. If the size is found to be above specifications, the tube is passed through a continuous heating furnace and then through an electrically operated continuous reducing mill, which is expected to bring it up to the size called for in the order.

Every tube is inspected for wall thickness and interior imperfections, which is done by holding an electric lamp at one end while the inspector looks in from the other.

Fig. 14 Section of Solid Steel Bar During the Piercing Process (Left) and Section of Tubing During the Cold-Drawing Process (Right)

Another section of the plant takes care of the production of cold-drawn tubing. In this process one end of the tubes is heated in a gas-fired electric furnace and the heated end is pointed by means of a Yeakley-type power hammer. The tubes are then pickled in a solution of sulphuric acid and rinsed in water in order to remove as far as possible all scale which adheres to the surface. A lubricant is then applied to the surface of the tube after which it is passed over a shafting and fed into a die. It is then drawn to the size called for in the order. The drawing machines are both of the single-chain and double-chain types.

The drawing makes the tube extremely hard and brittle, so that it becomes necessary to put it through a process of annealing. Tubing intended for mechanical purposes is given only a slight anneal, while boiler tubing is made fairly soft. (*The Iron Trade Review*, vol. 64, no. 4, January 23, 1919, pages 259-264, 11 figs., *d*)

MOTOR-CAR ENGINEERING

Steam Agricultural Tractors, Dahme (*Zeitschrift des Vereines Deutscher Ingenieure*, Nov. 16, 1918). This article, which is well illustrated and is to be concluded in another issue, describes the latest road tractors constructed by the firm of R. Wolf, A.-G., in Magdeburg.

The boiler is tubular and is designed for pressures up to 10 atmos. The superheater is in the smokebox and consists of a large number of vertical spiral wrought-iron tubes of small diameter, which are set in parallel groups and through which the steam passes, flowing in a direction opposite to the passage of the exhaust gases to the smokestack. Steam temperatures up to 350 deg. can by means of this superheater easily be obtained.

The superheater and the boiler tubes are cleaned by means of a number of small steam jets playing into the smokebox in both directions, which effectually remove all matter adhering to the tubes.

The bunker is of sufficient size to take fuel and water for a 20- to 30-km. run, and the engine is supplied with a steam-jet suction pump for procuring the water en route.

The control of the engine is so arranged that it can be driven forward or reversed by the movement of a single lever. The steam supply is automatically controlled for hills, so that it is increased for ascending and decreased for descending. This arrangement can be put out of action whenever a very heavy load is being hauled, by the adjustment of a single screw.

In running this tractor as a stationary engine a great advantage is the fact that it runs as satisfactorily on the reverse as the direct, and, in consequence, crossed belts can be eliminated, and the automatic control is a great assistance in dealing with sudden intermittent heavy loads.

These engines are equally suitable for all kinds of road traction, driving sawmills, threshing machines, and the like. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 1, Jan. 7, 1919, no. 3746, p. 7)

POWER PLANTS

Elimination of Oil and Air from Feedwater (*De Ingenieur*, Nov. 9, 1918). In a paper read before the Department of Marine Engineers of the Royal Institution of Dutch Engineers by J. C. Dijxhoorn, the importance of perfectly clean feedwater for steam boilers is dealt with. The presence of cylinder lubricating oil in the condensed water is always a likely source of trouble. Numerous devices are resorted to in order to overcome this, as, for instance, trays with suitable porous material through which the water can move forward and backward while the oil is deposited on the material; coke filters, in which the oil adheres to the surface of the coke; or pressure filters, in which the contaminated water is forced through filter cloths which retain the oil.

None of these appliances have succeeded in completely removing the oil, because it is in an emulsive state and divided into globules of less than 0.001 mm. diameter, which can pass through the finest filtering medium. Various precipitants are mentioned, but success depends in every case on subsequent filtration of the water through large sand filters.

The tiny globules of oil can be made to coalesce by passing an electric current through the water, and the author describes an apparatus he has designed for this purpose, using continuous current at 110 volts while the water flows through the feed pipe. The electrically treated water is then sent through a pressure filter consisting of perforated cylinders covered with cloth and enclosed in a strong vessel provided with inlet and outlet stop valves. Such a filter has very little effect on ordinary feedwater, but, as the electric process described above causes the oil globules to coalesce, the whole of the oil is effectively retained, leaving pure water only to pass through.

A pressure gage on the filter indicates the condition of the filter cloth, which must be changed when the pressure rises much above boiler pressure. It is also important to remove the air from feedwater, and the author describes a special apparatus he has designed which automatically accomplishes this. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 1, Jan. 7, 1919, no. 3760, p. 10)

Elimination and Recovery of Oil from Feedwater. (*De Ingenieur*, Nov. 30, 1918). An account is given of an oil-recovery plant used at the Central Station in Flushing. It is similar to the Perrett plant used in England during the last 15 or 20 years. The feedwater is first allowed to flow through a brickwork tank having baffle plates with openings at the bottom, while the oil which rises between the plates is removed through a valve and freed from water and dirt by being passed through a centrifugal separator.

The feedwater is then conducted to a second tank fitted with metallic baffle plates charged with continuous current at a pressure of 8 volts. Emulsified oil again separates as a layer between the plates, and can be recovered as before. The feedwater is finally passed through a coarse filter, which removes the last traces of oil. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 2, Jan. 21, 1919, no. 3905, p. 41)

RAILROAD ENGINEERING

Heavier 2-10-2 Type Locomotives Built for the Pennsylvania Lines. Description of the locomotives built for the Pennsylvania Lines West of Pittsburgh by the American Locomotive Company. These locomotives are notable for two reasons: First, the total weight is greater than that of any engines of this type previously built and yet they are able to operate on 23-deg. curves. Next, they are equipped with pilots capable of meeting requirements for road or yard service. Also these locomotives are extremely heavy though they are to be used on a division with low grades. Locomotives with five coupled pairs of driving wheels and a lateral-motion driving box on the front axle cannot traverse curves sharper than 16 deg., and the present locomotives had to be equipped with the Woodward floating axle on the front and rear drivers to enable them to pass 23-deg. curves.

The equalizing system is considered to be a very unusual departure from standard American practice, namely, a four-point suspension. The leading truck is equalized with the front driving wheels; the three center drivers on each side are equalized together and the rear drivers are equalized with the trailing truck. The valve motion, which is of the Walschaerts type, has an extremely long travel which is secured without excessive angularity by the use of a long radius rod and a long link combined with an eccentric crank of large throw. This gives a travel of $8\frac{1}{2}$ in. The experience with consolidation locomotives has shown that the theoretical advantage of long valve travel is borne out in actual practice.

It is interesting to note that tubes of $2\frac{1}{2}$ in. diameter are used in the boiler. It is stated, in this connection, that while the total heating surface is decreased by the use of such large tubes, experiments have demonstrated that as tubes are lengthened beyond a certain point the evaporation does not increase proportionately. The most desirable ratio of length to internal diameter is approximately 100, such a ratio being secured in this instance by the use of $2\frac{1}{2}$-in. tubes. (*Railway Age*, vol. 66, no. 4, January 24, 1919, pp. 249-251, 3 figs., *d*)

New Departure in Firebox Construction. Description of an installation recently tested out on a Chicago, Milwaukee & St. Paul locomotive designed by the Nicholson Firebox Company, of Chicago, Ill.

The installation as shown in Fig. 15 is called a thermic siphon and is so disposed as to displace the arch tubes hitherto depended on to support the firebrick. Each element consists of an approximately square plate of firebox steel folded on itself along a diagonal in such a manner as to resemble a flattened cornucopia. The lower extremity of the siphon is flanged into tubular shape and is inserted into and secured to a throat sheet of the firebox, giving to the tubular portion a slope corresponding to that of the customary arch tube.

The purpose of the use of thermic siphons is double: namely, to utilize to better advantage the radiant heat transfer available, and to accelerate the water circulation within the boiler.

Practically all of the heat absorbed by the heating surfaces of the ordinary firebox is radiated from the fuel bed and from the flames to the heating surface. The siphons break up the flame into several channels, thereby increasing the flame radiating surface, which is equivalent to increasing the firebox heating surface, so that with the same flame temperature a greater quantity of heat may be radiated to the surfaces of a firebox thus equipped.

Referring to Fig. 16, it appears that firebox *B* equipped with the siphons evaporated approximately 5000 lb. per hour more than firebox *A*. While the shape of the flame passages in *B* would tend to increase the heat absorption from the hot gases by direct contact or convection, the amount of heat so absorbed would still be very small compared to the amount of radiant heat absorbed from the flames.

The second purpose of the use of the flame siphons is that of increasing the amount of water circulation. The volume of water

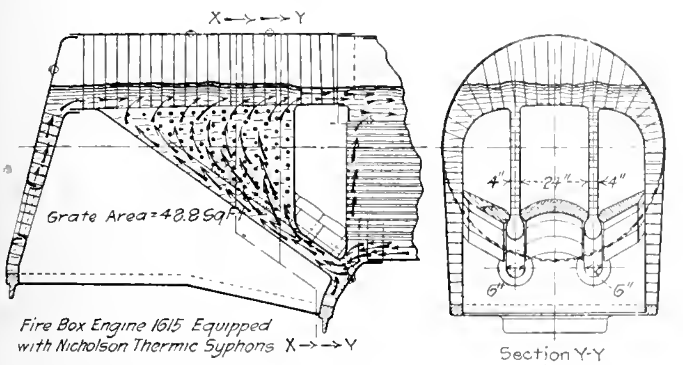

Fig. 15 General Arrangement and Scheme of Operation of the Nicholson Thermic Siphon for Locomotive Boilers

circulated through a pipe, such as an arch tube exposed to the high firebox temperatures, seems to be greatest when the volume of water and steam discharged at the outlet are about equal, and this condition prevails when high firebox temperatures are obtained. The ratio of the average cross-sectional area of the water passage of the siphon to the perimeter, or the heating surface, is practically the same as that of an arch tube, and it is reasonable to suppose that under similar conditions of temperature the proportion of water and steam discharged would be the same. Assuming, however, that under normal conditions of working and firebox temperatures, the steam leaving the outlet of the siphon carried with it only half its volume of water, the circulation through the two siphons is found to be sufficient to cause all of the water in the boiler to pass through them every five minutes, and at the highest rate of working the velocity of circulation practically would be doubled.

With such high velocity of circulation as is here indicated and with such large volume of water siphoned through the inlets in such a short space of time, it is apparent that no cold water could collect in the belly of the boiler, or remain there long.

The siphons are located so as to take advantage of the natural trend of circulation in the boiler and give greatly added velocity to it. The cold water fed in finds its way to the bottom of the boiler and slowly travels back toward the firebox. The siphons draw their water supply from this ordinarily cold zone at such a rapid rate that the cold water fed in is quickly drawn back to the throat and siphoned through the hottest zone of the firebox where it is heated up to the temperatures of the steam and partly evaporated.

The water at steam temperature discharged from the top of the siphons travels forward toward the front flue sheet, thereby tending to draw the cold water up from the bottom of the side and back water legs. Under such conditions of circulation the water is maintained at a nearly uniform temperature throughout the boiler, and this should result in a marked decrease in the prevalent boiler troubles due to the unequal contraction and expansion caused by wide variations in the temperature of the water in different parts of the boiler.

The article describes in some detail and illustrates the method of attaching the siphons. (*Railway Review*, vol. 64, no. 2, Jan. 11, 1919, pp. 47-51, 5 figs., *d*)

Three-Cylinder Locomotive for Constantinople (*Zeitschrift des Vereines Deutscher Ingenieure*, Nov. 9, 1918). A ten-coupled three-cylinder goods locomotive supplied to the Constantinople Military Authorities, by Henschel, of Cassel, is described and illustrated. The advantage of the three-cylinder type over the two- or four-cylinder types, especially for goods locomotives, are clearly pointed out. Tests were made with two three-cylinder locomotives, one with all three cylinders horizontal and the other with the two outer cylinders horizontal and the middle one inclined upward at 1 to 6.143. By having three cylinders, the large diameter (686 mm.) required for a two-cylinder engine was avoided. The starting of the three-cylinder type is better owing

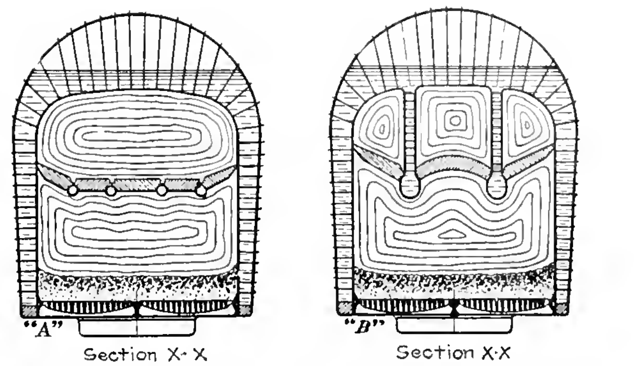

Fig 16 Flame Radiation in Locomotive Fireboxes with and without the Use of Nicholson Thermic Siphon

to the distribution of the turning force on the three-crank axle, and the draft on the fire is more regular owing to the 50 per cent increase in the number of the exhaust blasts. The angle of 120 deg. between the cranks as obtained on the three-cylinder engine is the most efficient turning angle.

The locomotive was designed for a maximum speed of 45 km. per hr. and to pull 500 tons up a gradient of 1 in 20 at a speed of 15 km. per hr. The leading dimensions are as follows:

Cylinders, diameter	560 mm.	Adhesive weight	78,600 kg.
Piston stroke	600 mm.	Tender wheels, diameter	1,018 mm.
Driving wheels, diameter	1,250 mm.	Tender wheel-base	3,300 mm.
Leading wheels	820 mm.	Tender water capacity	12 cu. m.
Total wheel-base	8,500 mm.	Tender coal	7,000 kg.
Total boiler pressure	13 kg. per sq. cm.	Tender weight empty	18,170 kg.
Area of grate	4½ sq. m.	Tender weight loaded	37,170 kg.
Heating surface of firebox	16.13 sq. m.	Total wheel-base for locomotive and tender	15,000 mm.
Heating surface of tubes	225.22 sq. m.	Overall length of locomotive and tender	18,235 mm.
Heating surface of superheater	80.88 sq.m.		
Weight empty	82,560 kg.		
Weight loaded	91,290 kg.		

The engine has 80 mm. sideplay each side on the front wheels and 25 mm. on the second and fifth coupled wheels for turning curves. The center line of the middle inclined cylinder passes 100 mm. vertically above the center line of the crankshaft. The two outside cranks are set at an angle of 120 deg. to each other, and the middle crank at an angle of 130 deg. 31 min. to the right-hand crank and 108 deg. 29 min. to the left-hand crank.

Ten of these locomotives were supplied to the Military Authorities at Constantinople. Several goods and passenger engines of the type have been supplied to the Prussian State Railways. (*Technical Supplement to the Review of the Foreign Press*, London, vol. 3, no. 1, Jan. 7, 1919, no. 3747, pp. 7-8)

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer.

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

The House passed a bill on February 18 extending the life of the Screw Thread Commission for one year. The matter at this writing is now in the Senate for approval. The commission, it will be remembered, was appointed for six months in October, 1918, by the Secretary of Commerce. While its work has advanced to a point where a tentative report is being prepared, the added time is much needed for the proper completion of so important and intricate a matter.
